Now it is the firſt Article only which we ſhall at preſent conſider, ſince we apprehend the Things which concern that will be the moſt readily underſtood, by Perſons not very converſant in Affairs of this Nature, and will the ſooneſt anſwer Expectation, where there are proper Opportunities of carrying them into Execution. Things of immediate Uſe to us, being of greater Conſequence than the moſt curious Speculations in which we are leſs intereſted. PYTHAGORAS's Rule is excellent. "Search profitable Knowledge. "Whatever Time is ſaved, Inconvenience re- "moved from, or Advantage gained to a Gentle- "man's Servants in his own Family, or to or "for his Tenants or their Servants, out of it, "ſo much additional Wealth he certainly ſaves "or gains yearly in his Expences, or to his "Eſtate, either directly or in the Conſequences "of it."

This Rule is alſo applicable to every Farmer and Labourer, and indeed to every Station of Life, from the Coronet to the Cottager.

But as Examples and Inſtances make deeper Impreſſion than Rules or Precepts, I ſhall here mention a Caſe of my own, in a Particular of this Nature.

When I purchaſed the Eſtate I ſince lived at; I found a Well, with its uſual Conveniences, about ſixty Yards from the Kitchen Door, and when

I had fixed a Pump there, ſtill found the Expence of carrying Water, taking in Brewing, Waſhing, and other Accidentals, full half a Crown a Week: on which I laid the Water into the Houſe from a Ciſtern, placed under the Pump; which was covered and contrived ſo, that it muſt be near full before the Water could flow out at a Spout, near the Top of a Ciſtern, before the Men Servants, or Neighbours, could have any for their Uſe, or receive it in under Ciſterns for Horſes or the Cattle to drink at. By which Means the Houſe was generally ſupplied with Water, without the Servant's going out to pump.

The whole Expence was about eight Pounds, and one Pipe was laid into the Kitchen, one to the Waſh-ſtove in the Brew-houſe, one to the Side of the Copper (for the Level would not carry it into the Copper, but the Water was eaſily laded into it, out of a Tub which ſtood under a Cock cloſe by it) and another Pipe was laid into the Garden, to water that.

I preſume, I need not mention the Eaſe and Saving this one Article procured, beſides the Water's being better and freſher this Way, than the other.

And I believe proportionable Advantages will be found in moſt, if not all, the general Improvements after-mentioned.

Every Farmer will find the Difference of milking near Home, and at a Diſtance; in one Place only, or in different Paſtures.

And every good Oeconomiſt will contrive his Affairs, as far as he can, with Prudence, ſo that what is moſt wanted ſhould be the neareſt, and thoſe at the greater Diſtance which he, or his Family, have leſs Occaſion to reſort to.

The Subſtance of thoſe I call natural Improvements, may be compriſed under the following Heads:

Commodious Buildings;

Laying Farms and Lands conveniently together;

Dividing large Grounds into leſſer of proper Quantities;

Keeping up good Fences and Places for Shelter;

Supplying Grounds with Water to float them, where that can be conveniently done, and making proper watering Places where wanted;

Taking Water off, or draining Grounds which are too wet;

Proportioning Corn Land and Graſs Ground properly for the Farm;

Making good Roads;

And laſtly, I ſhall juſt mention the Alteration Time makes in the Value of moſt Lands; which may be of Uſe to ſeveral Gentlemen and others, to have it obſerved to them.

1. Of commodious Buildings;

We ſhall not, under this Head, launch out into the Manner, Method, or Expence of Buildings at large; which depend ſo much on different Situations, Prices of Materials, and Wages of Workmen in different Places; and which, if expedient, would fall more properly to be conſidered when the Farmer's Houſe and Out-houſes, &c. are treated of: but here I ſhall only obſerve, that large Timber is commonly one of the greateſt Expences of Building, and that great Roofs require the greateſt Expence to ſupport them: and in Farming Affairs a narrow and long Building will commonly anſwer the End full as well, or better than a ſhort and wider one, and that at a much leſs Expence; except where they throw their Corn in order to clean it, which requires Space for that Purpoſe, the Expediency of which Method will be hereafter conſidered.

In other Caſes, having Room to thraſh in the Barn, and a Door toward the South Weſt Wind, the Farmer will ſeldom want a Wind to clean his Corn; and when ſuch a Caſe happens, a Hand Fan will eaſily ſupply the Want of it.

As to Standing for Beaſts, thirteen Feet wide will do for four, whereas ſix require twenty Foot wide; and every Perſon of any Experience well knows, that a Roof of above twenty Foot wide, and the Expence of after keeping it in order, will far exceed that of thirteen Feet wide with the Addition of ſeven or eight Feet more in length for a third Row of Beaſts; which Remark may be eaſily and uſefully applied to many other Caſes.

As to the monſtrous great Barns formerly erected at ſuch a vaſt Expence, as are to be met with in ſeveral Places, they are very little valued now; ſeveral judicious Farmers refuſing to uſe them ſo much as they might: apprehending their Corn and Hay to be better and ſweeter, when ſet in Stacks in the open Air, than when houſed. And in many Places the tying up their Beaſts, at any Time of the Year, for the whole Night, is generally omitted, and they find them to do as well.

But what is of much greater Concern under this Head, is the Benefit which ariſes to the Owner of a Farm, both as to the Eaſe in the Management of it, and alſo as to the preſerving it in a proper State of Huſbandry. When the Buildings are prudently placed in the Ground, in Compariſon of thoſe placed at a Diſtance, or ſituated in low Places from which the Manure can ſcarce be poſſibly returned to the Land again, and what is ſo conveyed is at a great Expence; and conſequently the upper or diſtant Land muſt be gradually impoveriſhed.

Whereas, when the Buildings are on the Level with the Land, and in the Midſt of it, the Manure cannot be loſt, and the whole Courſe of Huſbandry will be carried on with much more Eaſe, and at a much leſs Expence.

The Advantage of ſuch a Procedure I ſaw made very plain, by removing an old Houſe which ſtood in a Village diſtant from the Land, into a proper Place in the midſt of the Farm; by which Means they always milked at the Door; and one Man, Woman, Horſe, and Sledge, managed the ſame in general with as much Eaſe, as two Men, two Women, a Cart and Horſes did before. And any one may eaſily compute how much was got or ſaved by it in the Year.

There are very few large Quantities of Ground, but ſome proportionable Advantages of the ſame Nature may be procured, with a little Diſcretion, at a very moderate Expence.

Lee Walls (as they are called) are frequently erected much in the Shape of a great L, both on Commons, and in large Paſtures, by common

Tenants, to ſhelter Beaſts and Sheep againſt ſevere Storms, and violent Winds from every Point of the Compaſs. The Benefit of them is very well known; and I have often wondred that ſomething of this Kind is not more frequently to be met with in many Grounds near London, and ſeveral of the Marſhes in Kent and Eſſex, where there are ſo few Out-fences to ſhelter the Cattle from Wind and Weather.

A ſmall uſeful Building which would very well anſwer this End, might be contrived at little Expence; and eaſily conſtructed ſo as to be taken in Pieces, and carried from one Place, and ſet up in another.

In an Affair I had in a bleak Marſh in Eſſex this Summer, with two Men in one Day I made a Shelter on a riſing Ground for the Workmen, and ſo on, by ſinking the Ground above a Foot, and making the Side Walls and back Part of the Turf and Soil, and then covering it with Boards, which anſwered every End propoſed, and will do ſo till the Work is compleat, and the Wood carried away.

When the late Czar of Muſcovy built Petersburg, he contrived the Houſes ſo that one of them might, on Occaſion, be taken down in two Hours, and eaſily ſet up again in another Place.

And when Sir Walter Rawleigh went againſt the Spaniards, he carried all the Parts of the Veſſels he was to uſe there, ready to be immediately joined together when they came to the Place appointed.

A Roof alone might be ordered ſo as frequently to be uſeful to ſet over a Quantity of new Hay in Summer, till a large Rick be made, or even to cover the Rick till it was finiſhed in the Nature of a moveable Dutch Barn; by which Method a good deal of Damage, and a great deal of Trouble, frequently occaſioned by intervening Rains, might be, in a great Meaſure, entirely avoided; and there are few Farmers but ſuffer yearly by Rains one Way or other, before their Hay Ricks and Corn Stacks are ſo well covered as to be effectually ſecured.

Some uſe old Tarpawlins, which may be of ſome Service, and ſo would two or three Fleaks thatched, and hung croſs a Rick, which any Farmer may very eaſily procure, or make for himſelf.

And why might not ſlight moveable Buildings, as above-mentioned, be of equal Uſe to our Horſes and Cattle in Summer, by affording them a ſure Shelter againſt the violent Heats, and other raging Inclemencies then predominant, as they do in Winter againſt Storms, Froſts, and exceſſive Colds.

Our Bodies, and thoſe of our Beaſts, are probably, in a great Variety of Inſtances, more like one another than many Perſons are willing to allow.

Are we not ſubject to the ſame Sorts of Diſeaſes, and are we not alike proportionably ſenſible of Heat and Cold, piercing Winds, and violent Storms.

The Hiſtory of Jamaica aſſures us, that there are Times, when, unleſs the Labourers put on their Cloaths, they will be in great Danger of loſing their Lives; and in ſome Places with us, piercing Blaſts have been almoſt as prejudicial, and ſome Winds certainly ſubject us to particular Diſtempers, which are ſoon perceived, and occaſion others, though we are not directly ſenſible of them at the Time of the receiving the Contagion.

Every Houſewife is ſoon ſenſible of the ill Effects ariſing from the Cows being hurried about in hot Weather, both as to the Goodneſs and Quantity of their Milk. And I know a Farm in Cheshire which, on a moderate Computation, is thought to be damaged five Pounds a Year by the Cows being deprived, by a Navigation, from ſtanding in a River in the Heat of the Day; and the Prejudice to the Paſtures, by their gadding and running about, is very well known.

Any good Workman would eaſily contrive Buildings of this Nature, and we have ſome Plans of ſome ſuch Sort of Buildings, which we ſhall communicate.

The next Head we have to conſider is,

The laying Farms and Lands conveniently;

We have before mentioned two or three Inſtances of the great Advantages of laying Land commodiouſly together.

Every experienced Farmer will allow, that two Acres together, of the ſame conditioned Land, is of as good Value as five half Acres in diſtant Places in the ſame open Field; the Advantage is proportionably greater when the Portions of Land are leſs; and it is not uncommon to find many Parcels of Land both in open Fields, and good Meadows, containing much leſs; which when laid together and incloſed, are often more than double or treble the Value they were before; eſpecially near great Towns, or in Countries where Graſs Ground is ſcarce. And I believe, within my Memory, there have been fifteen hundred Acres of Field Land incloſed near Derby, which from eight or nine Shillings an Acre, whilſt in the open Field, is now let from three Pounds to twenty Shillings per Acre, and on an Average at about thirty Shillings.

This leads us to the dividing one Part of large Grounds from another, in proper Quantities.

This, as to the beneficial Part, depends pretty much on the ſame Reaſoning as the laſt Articles; and to the Inſtances before given of the Benefit of it, I ſhall here add another of a formerly remarkable Piece of Land, called Haddon Paſture, near Haddon in Derbyshire, the antient Seat, and Place of Reſidence, of the Duke of Rutland's Anceſtors. Mr. Lawrence tells us of Mill-Stones dug here: but he errs: this Author ſhould not have been ſo ſevere upon others, unleſs himſelf had been more free from Faults. This was a large Piece of Lime-ſtone Ground, and uſually joiſted by taking in Beaſts from all the Country over.

It has been lately divided into ſeveral Parts, by the Perſon who took it, with Lime-ſtone Walls, and ſet out again to under Tenants for two hundred Pounds per Annum more than the original Rent, or than was made of it whilſt it was kept as a fine Paſture.

I could give ſeveral other Inſtances wherein I have been concerned, of the ſame proportionable Profit ariſing ſolely by the parting large Grounds with Lime-ſtone Walls, in Counties where that Material is to be had; which, though

not

not ſo ſightly, may perhaps be found the moſt beneficial Fences in the whole Kingdom.

Where Lime-ſtone is to be had in the Ground, any thing near, the Stone will be got, led, and walled ſeven Quarters high, for about four Pence per Yard forward: and you immediately enjoy the Benefit of this Fence. The Foundation is but about two Feet broad, there are no Ditches on either Side, or any Loſs of Ground near them; for the Scythe may cut, or the Plow and the Cattle have Shelter and Meat, cloſe to its Side.

Again, here are no Roots to run into and rob the Corn, no Branches to drop on it, nor any Inconveniences of that Kind, which are uſually objected to the dividing Corn Fields into leſs Pieces than ſixteen or twenty Acres; and theſe Walls certainly nouriſh the Land ſeven or eight Yards near them, and receive the Nitre of the Air; for when an old one is pulled down it ſmells ſtrongly of it. Many are very warm againſt any Plowing nearer the Hedges than ſeven or eight Yards; and a very judicious Farmer told me, that he never expects or finds above half a Crop near the Hedges, in proportion to what he reaps in the Middle of the Field.

This Remark therefore ought to be minded, in thoſe Places where the Culture of Corn is principally deſigned. And I have obſerved that near St. ALBAN'S, and toward HEMPSTEAD, the Corn Fields are generally pretty large, twenty Acres or more each.

Where new Hedges are to be raiſed, a good white Thorn is certainly the beſt; and if planted in proper Ground, may be made to ſave itſelf in four or five Years, and one dead Hedge, once repaired, will generally ſerve to guard it till it is ſafe.

I once planted a Hedge of this Kind with ſtrong Sets out of the Woods, of above an Inch Diameter, ſet them eight Inches aſunder, and cut them within eight or nine Inches of the Ground; and ſome of them (which I let grow to try what they would do) ſhot that Year ſix Foot high, and all ſoon made an Hedge for Cloths, when cut and kept in order, four Foot deep, and a Yard over; but theſe Sets were planted in good freſh Soil.

I had pretty much the ſame Succeſs with ſome Thorn Buſhes I removed for the ſame Purpoſe, cutting the Heads in Proportion to the Loſs I apprehended the Roots had ſuffered by being tranſplanted, and they ſoon anſwered what I expected; and I believe the white Thorn, if indulged, would grow large, and be tranſplanted like other Trees. I have let ſome choice ones grow as large as Trees in Fences; and there are ſome ſingle ones on the DERBYSHIRE Moors near MIDDLETON, by YOULGREAVE, which are as large as middling Aſh Trees. Theſe being about a Mile diſtant, are very good Guides to Travellers; and I preſume were formerly planted there for that Purpoſe, there ſtill lying about them many looſe Stones, which I ſuppoſe were Walls round them.

This Method of raiſing white Thorn is not what is uſually practiſed. But I cannot but think, from the Nature of this Shrub, that the Deſign of a Gentleman of my Acquaintance, was both reaſonable and feaſible.

He ſet in two Acres of Ground many Rows of white Thorns, which one out Fence ſecured. Theſe, when grown up, ſupplied him with a ſucceſſive Stock of Thorns; and when he had Occaſion to take in any new Piece, he took Part of this to about a Yard high, and ſet them as a new Fence, the Thorns fenced the Outſide, and the Ground being Corn, and nothing admitted into it after the Corn, at the End of the ſecond Year it made a very good Fence. I ſaw not the Event of this, but another Gentleman aſſured me, he had practiſed it with great Succeſs.

Such a Trial can be no great Hazard, the young Sets may be bought at about four Pence per Hundred, which, at nine Inches Diſtance, will go a great Way; and if they are to be rais'd from the Berry (which generally come not up till the ſecond Year) there is a Method taken from an Experiment of Sir ISAAC NEWTON'S publiſhed by Mr. BRADLEY, of bringing them to ſprout in the firſt Spring, by placing them in Wheat Bran, kept warm, and ſometimes wetted a little. And this I tried, and found they ſprouted in Spring, but if too much wet be given them, it will be in danger of rotting them.

I have a great Diſlike to black Thorns, on Account of their ſpreading (frequently ſeven or eight Yards) in the Ground, and neither they or Crabs muſt be admitted in a cloſe Hedge, they both ſtaining them very ill; as white Thorns will do juſt after cutting, but if a Shower intervene, or a few Day's Time, theſe do little Prejudice in that Kind. And Thorn is of ſo hardy a Nature, as to thrive where few Trees will, ſo it may be uſed as a good high Hedge, or as a Row of Trees, to ſhelter againſt cold bleak Winds; and I have ſeen ſuch a Hedge grow amongſt Elms, which, cut properly, ſeemed to be one entire cloſe Fence, of forty Foot high.

As to dividing of Graſs Ground into ſmall Parcels, many are of Opinion, that one Cloſe of ten Acres will maintain as many Cattle and as well as four Cloſes of three Acres each; the principal Reaſons they give are, that in leſſer Grounds Cattle quickly walk over them, and being ſullied and ſtained with their Feet, they will not care to feed thereon; whereas, in larger Fields they have Room to range and feed, till the ſtained Places be refreſhed with Rain or with the Dews, that there is a Loſs of Ground by Hedges and Ditches, that 'tis eaſier to get Water in a great Piece than a little one, and that Cattle love a large Walk, and like not Graſs under the Dropping of Trees.

To which it may be anſwered, that the dividing ten Acres into four Parts, allowing two Yards for the Hedge and Ditch, takes up but about one ſixth Part of an Acre; that if there be Water it may be eaſily laid to two or three of the leſſer Cloſes, or that may be eaten firſt which has the Water, and then laid to, that the other Hedges and Trees may be kept down, ſo as not to ſour the Graſs much; or if permitted to grow will be of above an equivalent for that Damage. And when they are eaten by Turns, the firſt will be wonderfully recovered and ſweetened, before the Cattle are brought back to it; and it is not to be imagined what Conveniencies ariſe from

four or five ſuch ſmall Cloſes; at the beſt managed Farm I know, they have ſix of them, they can go into or from the fold Yard, in which they can keep their Swine on Clover, and let them out each Night to their Supper; keep a Cow or two on good Graſs, for good Milk and Butter, a Horſe or two, to be ready on every Occaſion, and eat the others as proper, whether they be Turnips, Clover, or Graſs; or lead through them to farther diſtant larger Cloſes, or keep a Piece of choice Graſs, Clover, or Turnips, to top up fat Beaſts with, or ſupport them with at the Time other Paſtures generally fail.

There has been ſo much ſaid of Good Fences, and Places of Shelter, under the former Heads, that I ſhall only mention they are a Security of our Property to us, and the great Preſervers of Peace and Quiet in a Neighbourhood. They preſerve both our Grounds and our Cattle warm and well, and have ſuch viſible Good ariſing from them, that it becomes a Sort of a proverbial Saying, amongſt the Farmers in one of our Counties celebrated for good Huſbandry, That "A warm, cloſe, high Hedge, is half the Cattle's Meat in Winter, in cauſing that which is "given them to do them the more good," which is certainly as juſtly applicable to Shelters in Ground, as to Fences round Ground.

The next Article we come to is, the ſupplying Grounds with Water to float them, where that can be conveniently done, and making proper watering Places where wanted and ſuitable.

Where Lands are ſituated near Rivers or Brooks, or under riſing Grounds above them; the Benefit of floating of Meadows in dry Seaſons (and indeed at other Times) is frequently eaſily and very advantageouſly obtained; for Water is of that ductile Nature, that it may be eaſily guided from Place to Place, and near ſeveral great Towns there are many Meadows which muſt be mowed and cleared by Midſummer, lying common after, which owe their returning Fertility to the Waſh of the Floods overflowing them after the Hay is got in; for which Purpoſe thoſe Banks which were raiſed to ſecure the Graſs, whilſt growing, from Floods, are immediately after opened in ſeveral Places, to enrich the ſame Meadows by all the ſucceeding Floods, till the following Spring, when the Banks are again made up.

This is ſo fine a Way of improving, that whereever Water comes from off rich Lands, or is impregnated with the Waſh of any Town, ſuch a Floating is much to be deſired; and it is a very good Practice to mix Manure with common Water, ſtirring it as it paſſes, as the Water will, this Way, convey it in the moſt beneficial Manner to the Graſs Roots. But where none of theſe are to be had ſometimes in great Droughts, the conveying common Water over the Meadows, will be very beneficial.

But what is more immediately under our preſent Conſideration is, how to provide for that Want of Water, which is commonly the Caſe in Lime-ſtone, Chalk, Sand, and Gravelly Ground, which though they receive their equal Share of Rain and Dew from above, yet being porous and open, the Wet that falls ſoon ſinks into the Ground, and ſo is loſt.

In ſome Grounds of this Nature there are Meers of Water, which ſupply the Cattle with what is neceſſary for them to drink; and where ſuch are not to be met with, there are very few Quantities of Land where, in a low Place, the Rains may not be brought from the higher Ground, and a Baſon, or watering Place, readily made, by laying a proper Mixture of Clay, tempered like Mortar, or by a Bed of Lime-aſſe well beat together; and I am aſſured, worked Chalk will anſwer the ſame End, laid at the Bottom and Sides of a Pit or Pool dug for that Purpoſe, which, if well made, will laſt long and anſwer the Purpoſe, eſpecially at the End of Summer, and in Winter. But Care muſt be taken to cover the Bottom with ſome Sort of Pavement, to prevent the Cattle poaching Holes in it with their Feet; and the Reader need not be told there muſt be ſome Walls to keep the tempered Mortar ſafe on the Sides, as high as it is propoſed the Pool ſhould ſtand with it, and little Cuts, if neceſſary, to bring the Water from above, to the Place prepared for it.

The firſt of this Kind that ever I ſaw, was in a Gentleman's Lime-ſtone Park in Somerſetshire, which the Owner told me coſt him at firſt thirty Pounds, and ſoon failed, but the Breach being found and repaired, it had then ſtood firm many Years, and was a very large one; but ſmall ones are now made, where the Materials are near, for forty or fifty Shillings, and often ſo contrived as to fit two or three diſtinct Parcels of Land, by parting them in the Middle, or by looſe moveable Rails, to lay them to one Side or the other.

The ſame Gentleman had walled his Park high enough to keep in his Deer, with Lime-ſtone Walls, but they being higher than dry Lime-ſtone, will commonly ſtand long. He poured in two Beds of Mortar whilſt it was building, one at about two Foot high, the other about four, and the Wall then ſtood very firm.

Exceſs of Wet is often as prejudicial as the Want of it, which brings me to the Manner of taking Water off, or draining of Grounds which are too wet.

The principal Point, in this Caſe, is to find the loweſt Place by which the Water can be carried off, and there open a wide Trench, of Depth ſufficient to drain the whole, which may properly be kept open; into this ſide Croſs Drains may be laid and covered.

The beſt Method for theſe Croſs Drains is ſaid to be that uſed in Eſſex, by making a Trench near two Foot deep, not above two or three Inches wide at Bottom, then filling it with Thorns, or any rubbiſh Wood, and covering it by turning the Turf downward, and then you may plow. The Difficulty is to lay the Drains in the loweſt Places, in which the Eſſex Men are thought particularly ſkilled.

I have known, where Stones were in Plenty, little Suffs made at Bottom, and ſmall Stones poured on it a Foot deep, ſo covered up, which anſwered very well; and I have alſo known wet Grounds much mended by very ſmall Gutters, of four or five Inches wide, leading to proper Deſcents, and what came from them ſpread on the Ground, to prevent its being trod in again.

These are easily made, and easily kept open, and if deeper than the Roots of the Grass, will, on clayey Ground, carry off the Wet very well.

The proportioning of Corn Land and Grass Ground proper for the Farm, is an Article scarce possible to bring under any general Rules, especially since the new Husbandry has prevailed, by which the Farmer may keep more in Tillage, or Grass Ground of natural or artificial Grasses, as he pleases; and needs not want of either to employ such a Team as he thinks proper to keep, such Cows as he thinks proper to milk, such Cattle as he proposes to rear or feed; in most of which a judicious Farmer, if he has Ground enough, may make it answer any End he proposes, with proper Application of it.

One general Rule indeed there is, which he ought strictly to adhere to; which is, never to have more Ground in Tillage, or appropriated for Hay, than he can husband and dress well.

He had better have two good Acres of Corn than six of bad, or four of middling; and the Expence attending the worst, is as great as that of the best.

The same in Proportion may be said of Hay Ground; and in both Cases, if the worse Sort be pastured, or lie Fallow, it will be of some Benefit, and preparing itself for a future good Crop.

Of making good Roads.

The making Roads good meets with so general an Approbation, through the whole Kingdom, that there seems not to need any thing be said to encourage and influence Gentlemen, and others, to do it about their own Houses, and also to promote it in their own respective Neighbourhoods.

This might be generally compassed by the usual Labour of the Villagers, and a little Money expended under the Direction of a Person skilled in Affairs of this Nature; by which Method I have known Hills, before hardly passable by a single Horse, made almost as easy for a Coach as St. JAMES's Street is; and the Side of a Precipice made a safe common Road, without Danger or Terror to the Traveller, by a Wall being erected next the Precipice, which takes off the Terror, and is a reasonable Security to the Passenger.

The Ease of Mind, the Safety to Man, Horses, and Carriages, the cheap conveying of all Sorts of Portables from Place to Place on good Roads, and the Time saved by it, will soon be an Equivalent for the Expence, and perhaps extend its Usefulness to unexpected Distances; so that it may be a Blessing to a Country, and even to future Generations.

The greatest Improvement of this Kind which I ever knew, was betwixt WYCH and WORCESTER; for when I first travelled that Road they were beginning to mend it, I saw eight or nine Horses hard set to draw a Tun of Salt; but travelling there again some few Years after, I saw no Waggon had above four Horses, and some but three, to draw the same Quantity.

The ROMANS, whose Wisdom we are so ready to commend in some Instances, where they less deserved it, in this Particular certainly demand our Applause and Imitation; for they caused good Roads to be made from Place to Place, wherever their Legions came, and some of their Works of this Nature are still visible and useful amongst us, after all the Length of Time since passed.

To do Justice to CHESHIRE and LANCASHIRE, they have, I believe, laid out more Money in making good Roads, and to better Purpose, though Materials are very dear in many Places there, than any six Counties in ENGLAND, exclusive of Turnpikes; and most Farmers there have a Horse Pavement from their Doors to the great Roads; and some Gentlemen have expended an hundred Pounds, in paving from the Road to their own Doors, which in some Places would, if wisely managed, repair the Roads for some Miles.

It is scarce to be thought how far a good Paviour will carry on a Horse Causey in a Day, I speak within Compass when I name sixty Yards. And I had a Servant of my own, who with a Labourer to assist him, and Teams to lead to him, in a Lime-stone Country, made a new Road above eight Foot wide, and ninety long, in a Day, setting both Outsides with the largest Stones for near two Feet on each Side, where the Wheels run, and filling and raising up all the Middle with what we call Lime-stone Gravel (being small Lime-stone) which if not trod on, in a few Days, will bind like a Rock, and on which the Horses will tread freely, which they never do where the Roads are set with great Stones.

The late ingenious Mr. COOPER, of LEICESTER, who gained so much Reputation by mending their Roads so well, brought all his Work to the following Certainties.

Twenty up-heaped Strikes (or Bushels) were a Load, which, when first measured and levelled as usual, Laths were nailed on the Carts for ascertaining it for the future.

Each Farmer filled his own Cart, and had generally one Penny half Farthing each hundred Yards it was carried.

The Gravel was got and spread at one Penny per Load, and a Person appointed to see all fairly done.

He farther observes, That Water Gravel never makes so fine a Road as what is dug out of the Earth, but where that is easier to be had, being mixed with a sandy Soil to bind it, it will make a good Road.

In some Places we meet with a softish Sort of Gravel, having too large a Mixture of Clay, Marle, or Sand amongst it, which, though laid thicker on the Road than ordinary, will not stand one Year's Wear; and yet we have found that some Gravel, after screening it, as it is done for Gardens, and leaving what falls through behind, to make as good and durable Roads as any we have.

These Particulars I have taken from a Manuscript of that Gentleman's never published.

The last Article I have to mention here is;

The Alteration Time makes in the Value of most Lands.

This Difference cannot be said to be an Improvement, but an Alteration of the Value of Lands, arising chiefly from the additional Quantity

tity of Gold and Silver comparatively brought into these Parts of the World; so that, properly speaking, Gold and Silver may be said to be of less Value now than they were formerly, as an Ounce of either will not now purchase one half of the Quantity of the necessary Provisions for Life (exclusive of the Taxes laid on several of them) which they formerly did, and which it may be proper the Reader should be informed of.

The Rents reserved in Money, in College and other Leases, and the Rents paid in Corn, which in Queen ELIZABETH's Time were of equal Value, now are so different, that they are a full Proof of the Variation; for the half now paid in Corn, Malt, and so on, is at present above three Times as much in Value, as the other Moiety still paid in Money, as I have observed in the several Leases of that Kind which I have been concerned in.

A late Writer seems to think this to have been the single Case of one College, not knowing, I presume, that it was fixed so in general, by the great CECIL, in order to preserve a Subsistence for Bishops, Deans, Colleges, and so on; and if it had not been so ordered, most of those Bodies could not now have possibly subsisted on the Incomes of their Estates.

Hence we may infer, that Lands then let at twenty Shillings per Annum, should now, according to the Course of Things, be of the Value of near three Pounds, unless some extraordinary Circumstance varies any particular Case from the general Rule; as where the great Improvements made by Lime, and artificial Grasses on high Lands have sunk the yearly Value of those low Meadow Grounds, which, being enriched by the Over-flowing of the Rivers from the Lime-stone Mountains, pastured with Sheep, used to be the only Places where Spring Grass, and early fat Meat were to be had: it being also within Memory, how better Families were obliged to lay in great Quantities of Hung Beef for the Winter, very little of that Sort of Meat being then killed in that Season, even in the great Towns; whereas, since the above-mentioned Improvements by Lime, &c. Hung Beef is scarce ever heard of, and fat Beef is now to be had in almost every Village, in every Month in the Year.

There are several other Particulars which might be considered under the Title of general Improvements, but as they may also be treated of under some particular Heads, we shall leave them to be considered as they may fall in properly hereafter.

In the preceding Part of this Work the Reader has been led through all the various Soils usually to be met with in these Kingdoms, and the different Methods commonly taken to improve them by Dungs of all Sorts, as well as by the artificial Manures of Lime, Salt, and the rest: all which have been copiously treated of, and (after some other intervening Articles) the Method and Manner of Plowing, Sowing, Harrowing, and Rolling, have been sufficiently enlarged on; the several Grains, Grasses, and Roots themselves come now to be particularly considered.

But before we enter into the distinct Consideration of the several Sorts of Grains, Grasses, and Roots, usually [illegible] and practised in this Kingdom; we apprehend it will be proper to take a short View both of the Ancient and Modern Tillage, which have prevailed amongst us, which, when done in a plain and intelligible Manner, the Reader will be thereby the better informed, how to form a proper Judgment of the several Advantages and Disadvantages, and know how to govern his own Practice, and to fix to himself a fair Rule for his Conduct.

Of the old Husbandry.

The usual Method of Tillage in the Corn Counties in ENGLAND formerly was, and still is, in those Places where what is called the New Husbandry has not yet prevailed, conducted in the following Manner.

Each several Village in the Corn Counties generally had three distinct common Fields (or Sides, as frequently called) belonging to it, usually of pretty near equal Quantities; which three Fields were appropriated to three several yearly Courses of Tillage.

One of these three, each Year, is appropriated chiefly to Wheat, though sometimes it had Barley in it, and this has always born the Name of the Wheat Field.

The second is called the Pease Field, being sowed, for the most Part, with that Pulse, though Beans and Oats, as found convenient, are commonly sowed therein also.

The third Field, or Side, is called the Fallow Field, as not being sowed at all; but repeatedly plowed, harrowed, and manured, as the Owner judges best for his Land, in order to prepare it for the following Crop of Wheat or Barley, in the succeeding Year.

These three several Names are regularly successively applied to the said several Fields, according to the Course they come in, of being sowed with Wheat or Pease, &c. or lying Fallow.

These were the repeated successive Rounds of the ENGLISH Tillage, in former Ages; and they were found sufficient to produce good Corn, and that in great Quantities; and the same Method is still continued in those Parts of the Kingdom, where what is called the New Husbandry, has not yet prevailed.

The manuring, and two Year's due plowing, the two fallow Years (with proper plowing and sowing the other four Years) were found sufficient to produce four successive reasonable good Crops in the six Years; and those four such Crops again produced a sufficient Quantity of Manure, for the dunging the Ground during the said Circle of six Years.

But when Lime was found to be very beneficial for the producing of good Corn, and has been applied accordingly for that Purpose; where that could conveniently be had, it hath made the well manuring the common Corn Fields much better and easier, and rendered the less Dung necessary for the said four Crops in the six Years.

And though Corn was also formerly sometime sowed in inclosed Grounds, and much more so since the late Improvements made by Clover and Turnips; yet the open Fields always had, and still have the Preference, as producing the best and greatest Corn, and as the least subject

to Smuts and Blights; and it is alſo found, by common Experience, that Corn growing near an Hedge has not uſually ſo great a Quantity as that which grows in the Middle of the Cloſe; the Reaſon for, or Cauſe of which will be mentioned hereafter. The open Fields have alſo more of the Sun and Air, are leſs annoyed by Birds, and have leſs Fences to be taken Care of, thoſe being uſually made by the Lands adjoining to them.

There are ſome Inconveniencies the open Fields were always ſubject to, by their being generally divided into ſmall Parts, and thoſe the Property of different Perſons; for by Reaſon of this the Farmer is obliged to plow always the ſame Way, and never can plow the croſs Way, which is often found very uſeful for the Ground; and there are ſome other Inconveniences which the Owners of Field Lands are ſubject to, in order to preſerve the general Peace and Quiet of the Neighbourhood, ſuch as obſerving pretty much the ſame Times and Seaſons of plowing, ſowing, reaping, and fencing.

The dividing the common Corn Fields into ſo many very ſmall diſtinct Parcels, as they formerly were, and in ſeveral Places ſtill continue to be, to a ſurpriſing Degree, is worthy a diſtinct Conſideration. A Farm of mine, under thirty Pounds per Annum, containing one hundred and fifty-three Pieces, forty of which were not each a Rood, and two Acres no where lying together, and the whole Townſhip being alſo much in the ſame Manner, very few of the larger Eſtates having two Acres together in many Places.

This Method of dividing the Fields into ſo many ſmall Parcels, is generally thought to be owing to a political Deſign of our Anceſtors, to promote the Culture of Corn, by preventing the Fields being incloſed, as they were made the diſtinct Property of ſo many different Perſons.

But I preſume this Method of dividing the Ground was rather owing to the parting it amongſt the Followers and Soldiers of thoſe who ſucceeded in conquering, as a Recompence for their Services, according to ſome of the antient Military Ways of proceeding.

This ſeems moſt agreeable to the old Method of the Saxons, as evidently appears by the cuſtomary Mineral Laws in Derbyshire; by which, though the whole Mineral Field is at liberty for any Perſon to work in, yet if any one finds a Mine there, by that cuſtomary Law, he can take but ſo many Yards as the firſt Proprietor; and every other Subject, and he himſelf may take other Quantities of two and twenty Yards, one after another, till the whole be poſſeſſed or taken; but then, every diſtinct ſaid Number of Yards ſo taken, is a diſtinct Title and Poſſeſſion, and may be ſeparately owned by many different Perſons in Partnerſhip. This and many other Cuſtoms, prove that the Law uſed there is the beſt Remain we now have of the Saxon Method of proceeding, which was ſhort and clear, as the learned Doctor Hickes, and others, well ſkilled in our Antiquities, generally have ſhewn.

The Method before mentioned was, in general, the Courſe of the English Tillage, till the Introduction of the foreign artificial Graſſes, gradually within about eighty Years laſt paſt; and the Advantages by the ſowing thoſe Graſſes and Turnips, in the Incloſures, and alſo now in many of the open Fields, and particularly by that of Clover.

For by Clover and Turnips many of thoſe Lands which formerly were of very little Value bearing little Graſs, and no Corn, have been rendered very profitable as Graſs Ground; and alſo brought to produce very good Corn of moſt Sorts; and thoſe Lands both in the open Fields, and in the Incloſures which formerly were thought to anſwer well to the Plow in the Courſe of Tillage, have been greatly improved even in that Reſpect, by the ſowing of Clover and Turnips; and that third Year, which was before conſtantly in a great Meaſure, loſt by lying Fallow, is now generally made to produce a Crop of Clover or Turnips commonly worth, if tolerably well managed, at leaſt twenty or thirty Shillings an Acre, often more; which Clover and Turnips are ſo far from occaſioning any additional Expence, that they are found much the cheapeſt and beſt Methods of preparing the Land for Corn.

Theſe two, with the other artificial Graſſes, have given a quite different Turn to the general Courſe of our Huſbandry; and where the ſowing of Clover and other artificial Graſſes, and of Turnips and other Roots have prevailed, the Method of managing with and by them, has obtained the Name of the new Huſbandry; to which we may not improperly add the Method of Drill Huſbandry, which, though not ſo modern as ſome pretend, being introduced here by the late Earl of Sandwich, as appears by the Philoſophical Tranſactions *, the Inventor of it being Don Joseph de Lucatello, Knight, who had the ſame publickly tried in Germany and Spain, and had a Patent granted him by the King of Spain, about the Year one thouſand ſix hundred and ſixty-five, as the Inventor of the Drill Plow, called then the Sembrador, contrived to Plow, Sow, and Harrow at once.

* p[illegible] Tranſ. 2[illegible] Vol. 741-744.

But the ſame Method of Huſbandry being practiſed by the late Mr. Tull, who wrote a Book on this Subject, that Method has prevailed in ſeveral Places, and conſequently may be properly conſidered under the Head, and as a principal Part of the new Huſbandry; to which we ſhall now proceed.

Of the new Huſbandry.

The Advantages of this new Method of Huſbandry, when ſet in a proper Light, and compared with the former cuſtomary Tillage, are really ſo many and ſo great, as juſtly to entitle it to the Preference; and conſequently it very well deſerves the attentive Conſideration of every Perſon any way particularly intereſted in Affairs of this Nature, and who is not directly, or in Conſequence intereſted in Huſbandry on which our Suſtenance depends?

In our Entrance on the Conſideration of which, as we before ſtated the Courſe of the former Method of Huſbandry, in a clear Manner, to the Reader's View; ſo we will endeavour to do the ſame by this, as ſhort, clear, and fully as we can; but this modern Method, admitting many more Variations, both as to the different Sorts,

and

and the greater Number of Seeds to be ſowed, and alſo more yearly Changes of the Corn, than than the other does admit of; conſequently the Courſe of this new Huſbandry cannot be compriſed in ſo few, eaſy, and familiar Rules as the other was.

Indeed, in this there cannot be many certain Rules of ſucceſſively ſowing of Grain laid down, to be conſtantly followed, for a regular Succeſſion of Years; for in this new Huſbandry there being many more Grains, Seeds, and Roots to have their Turns in the Courſe of Tillage, they conſequently give the Farmer a much greater Latitude of varying and altering his Crops, ſo that he is not under that Neceſſity of repeating the ſame Species of Corn in the ſame ſhort Number of Years he formerly was.

By this new Method of Management it is propoſed, that the Farmer ſhall generally have ſix ſucceſſive profitable Crops, for ſix Years together, from the ſame Parcel of Ground, without the Loſs of any one Year, by letting it lye Fallow: at leaſt he may reaſonably expect eleven good Crops in twelve Years; and all theſe eleven or twelve Crops ſucceſſively, Year after Year, to be of as valuable Sorts of Grain, and as good in their reſpective ſeveral Kinds, and got too with as little Trouble, and at as little an Expence as the four Crops obtained in ſix Years, or as the eight in twelve Years uſually are in the open Fields.

In order to manifeſt the Truth of this, it will be neceſſary to ſtate the Courſe of this new Huſbandry in two or three different Methods, to make it the more plain.

Now by one Method Wheat may be ordered to have its Turn, or to be the Crop once in four Years. Thus,

First, Wheat.
Second, Beans, Peaſe, or Oats.
Third, Clover.
Then Wheat again.

Or Beans, Peaſe, or Oats, may be varied, and the Clover omitted, as the Farmer pleaſes.

By another, and in Appearance a preferable Method, the Wheat, Barley, or other Grain will ſucceed one another but once in ſix or ſeven Years; and may be ordered after the following Manner,

Wheat the firſt Year.
The Second, Beans, Peaſe, or Oats.
Third, any other of the laſt three.
Fourth, Turnips.
Fifth, Barley.
Sixth, Clover, and then a Return to Wheat, or any other of the Crops, for which the Ground will be well prepared again; or if it be liked better, the Clover may be continued two Years together, and will anſwer very well.

Reckoning the Clover as proper to be ſowed two Years in the ſix, by this Method here is a Proviſion for eight Years Crops, out of which the Farmer may chuſe any ſix of them he thinks the moſt ſuitable to his Soil and Circumſtances.

By ſuch a Method as this he reaps three of the richeſt Crops, and one of Beans or Peaſe, one of Turnips, and one or two of Clover, in ſix Years ſucceeding each other; whereas there can be but four obtained in the ſame Time, by the common Courſe of Tillage, and conſequently the new Method of Huſbandry has the Advantage of two more Crops in ſix Years, than the old Method of Culture; which, on Preſumption that the Crops are equally good in the Kind, is greatly to the Advantage of the modern Huſbandry.

All theſe ſeveral Grains and Seeds may ſtill be farther varied, many other Ways, as will hereafter appear, the better to prevent the too quick a Return of ſowing the ſame Grain again on the ſame Ground, which when done is generally attended with a very poor Crop, not only in every Grain ſowed in the Field, but alſo in every Herb and Root ſowed or propagated in the Garden, as is conſtantly experienced. Therefore every judicious Farmer, and every prudent Gardener, will carefully and conſtantly avoid ſuch a Practice, and will frequently change their Grain, their Herbs, and their Roots, from one Spot of Ground to another; till Time, or ſome Courſe of Huſbandry, hath prepared the Ground again ſufficiently for the producing another good Crop of the ſame former Grain, Herb, or Root. Nothing but Horſehoeing can ſet aſide this Neceſſity.

The Change of the Ground otherwiſe, as well as of the Seed to be ſowed, is of that Importance in the Courſe of Huſbandry, that we cannot preſs the Farmer too earneſtly to attend carefully to it in the general Courſe of his Tillage; though I know a very good Huſbandman has had a good Crop of Wheat, next one of Beans, then one of Peaſe, and then ventured to have Wheat again, and ſucceeded very well in it; but then his Ground was in very good Heart, and he knew Beans and Peaſe were generally good Grain to go before Wheat, and he himſelf thought it was full ſoon enough to ſow Wheat again with a reaſonable Expectation of very good Succeſs, without too much impoveriſhing the Land for a future Crop of Wheat.

A very little Conſideration will guide the Farmer in varying the ſeveral above-named Grains, Graſſes, and Roots, ſo as (with God's Bleſſing, and tolerable Huſbandry) to be reaſonably aſſured of obtaining good ſucceſſive Crops; or the continuing Clover two Years together will anſwer very well, as to the profitable Part: and on Courſe it will lengthen the Time one Year before the Return of another Crop of Wheat, and alſo of every other Sort of Grain, Graſs, or Root, by which Means the Ground will be the better repleniſhed with Nouriſhment for the firſt Crop again.

To the great Variety of different ſucceeding Crops, which may be contrived only from the ſeveral Species of Grain and Graſſes above-mentioned, the Farmer may eaſily add many other new Changes, by the ſowing of Rye, FRENCH Wheat, Lentils, Coleſeed, and ſo on; as may beſt ſuit his Land and Circumſtances, with which he may make ſuch various Changes, as to carry on a Courſe of profitable Tillage of the ſame Ground, to a much greater Length of Time than can be eaſily imagined, eſpecially after it has ſhared the Benefit of being marled, limed, or chalked. Four Bells will change or vary their Places ſo as never to come again in the ſame Order, four and

twenty Times; and five one hundred and twenty Times, and here are many more than five Sorts of Grains, Graſſes, and Roots, which may be brought into the Succeſſion of returning Crops, after the Manner mentioned of Bells, though not to ſo great a Degree.

But wiſe Farmers will not carry this to thoſe great Lengths; it might poſſibly be done with Profit if they could keep the Land clean, but will rather chuſe to lay down Part of the Ground they have in Tillage, with profitable laſting artificial Graſſes, or good natural ones; and break up ſome freſh Ground for Corn (for it cannot be imagined that any Farmer has all his Ground in Tillage at one Time) and by theſe Methods he may vary his Crops as he pleaſes, and give his ſeveral Grounds what Years of Reſt he thinks proper, before he brings them on again to a new Succeſſion of Grains, in a new Round of Tillage.

The Paſſion for the Plow is certainly very great in general, and for Wheat in particular, as it is the beſt, and commonly the moſt profitable Grain, but I believe, before this Syſtem be compleated, the Reader will be convinced that other Crops will often be found more beneficial, than to bring Wheat on again in two quick a Succeſſion, without allowing the Ground Time to gain proper Nouriſhment for it, tilling it properly, or manuring it with ſuch Dreſſings as to enable it to bring a good Crop again ſoon; without one or other of which Wheat is frequently found to bring in little Profit, and in ſome Caſes not to pay the neceſſary Expences and Rent.

To convince the Reader of the Truth of what we have ſaid, as to the Profit of the ſoon Return of, or reſpiting the Wheat Crop only for one Year, I will calculate the reſpective Profit which may be reaſonably expected from Wheat Crops in twenty Years, when each fourth Year, and when ſowed each fifth Year during that Period of Time, in which the longer the intervening Time is between, the better the Crop will pay.

Now in this Caſe, in the firſt Method there will be five returning Crops of Wheat in the twenty Years, and three Years between each Crop to manure or improve it; and it cannot be reaſonably ſuppoſed to produce above twenty Quarters of Wheat, that is, four Quarters each Wheat Year.

In the other Method there will be but four Crops of Wheat in the twenty Years, which, with the ſame Method of Huſbandry, and one fourth more of Time muſt, by the Rule of Proportion, be the better prepared by one fourth Part for the producing of ſo much a better Crop; which then muſt be five Quarters each four Wheat Years, which will amount to juſt the ſame Quantity of twenty Quarters in the ſaid twenty Years.

This Method of reckoning is not only agreeable to Reaſon, but on ſtating it in this Manner to ſome very judicious Farmers, they have judged it to be according to what they experience in their Courſe of Huſbandry; and that the Crops in general commonly are better or worſe, according to the Time allowed betwixt the freſh ſowing again of the ſame Sort of Grain.

I am not aware that I am guilty of any Miſtake in this Calculation, unleſs I may be thought to eſtimate both Crops too high, and if any Abatement of that Kind be neceſſary to the one, it is equally ſo to the other, and the Account will come to the ſame at the laſt, or rather, turn more to the Advantage of the four Crops; for five times three and an half would be ſeventeen and an half, and four times four and an half would be eighteen Quarters, and much the ſame will be produced if different yearly Produces are taken.

Now ſuppoſing the Profits equal in the Caſe of the four Years of Wheat in the twenty, there will be the Seed and Huſbandry of one Year entirely ſaved; and as it is probable that Clover might be continued the Year Wheat was omitted, or a Crop of Turnips got; ſuch a Crop, and ſuch a ſaving may moderately be eſtimated at two Pounds ten Shillings gained or ſaved in this Caſe, which may be equally applied to many other Caſes of the ſame Nature, which will eaſe him of ſuch Calculations which many are unacquainted with.

From what has been ſaid the Reader cannot but obſerve, that the Subſtance of all the modern Improvements, eſpecially as far as they relate to Corn and Cattle, are principally owing to Clover and Turnips, each of them producing great Quantities of Suſtenance for our Cattle, and at the ſame Time preparing the Land ſo well for Corn, that where they are properly uſed there is very little Occaſion for the Loſs of letting the Land lye Fallow, in general, but only on ſome very extraordinary Occaſions.

Thoſe two therefore muſt conſequently deſerve to be treated of, in a full and copious Manner.

And ſince Wheat is the principal Grain to be wiſhed for, and generally the moſt profitable when obtained, and Clover and Turnips, either directly or in their Conſequences, the beſt Preparatives for it; we ſhall conſider Wheat, Clover, and Turnips as the three chief and moſt excellent of Grains, Graſſes, and Roots, and endeavour to do Juſtice reſpectively to their many uſeful Qualities. In this Method we ſhall not only take in the principal Part of all what concerns the old Manner of Tillage, but alſo all the material Alterations and Improvements made by what is called the new Huſbandry, adding thereto ſome brief Obſervations on the Method of ſowing leſs Corn, and at a greater Diſtance than commonly practiſed; and I ſhall alſo take ſome little Notice of ſeveral Compoſitions and Manures, which have been lately found beneficial both to Corn, Roots, and Graſs Ground; and ſhall occaſionally touch on the Method of drilling the Ground.

We ſhall here obſerve ſome of thoſe Conſequences which the Prevalency of the new Huſbandry muſt neceſſarily produce, when it is conſidered on the diſadvantageous Side; where it may be thought to occaſion ſome Inconveniences or Hardſhips to others, leaving it to every Reader's own Thoughts, to judge of the good or bad Conſequences of it to the Community in general.

The new Huſbandry prevails principally in the South Parts of the Kingdom, and travels but very ſlowly Northwards, and conſequently muſt, at pre-

preſent, very much affect the North Country Farmers, and their Landlords in Courſe ſoon after; for if, by this new Method of Huſbandry, the South Country Farmer can really produce, by the ſame Ground and Huſbandry, but one fourth more profitable Grain, Graſs, and Root, in the Circle of ſix Years, than the North Country Farmer does, the South Countryman will be able to underſell the Northern, and conſequently the Northern Men muſt ſink, or their Farms fall in their Value, which muſt at laſt fall on the ſeveral Landlords.

The ſame Remark may be alſo made in Relation to the Vale Grounds, and the Uplands; for ſince ſuch great Quantities of good Hay have been obtained in the Uplands, by the Aſſiſtance of the foreign artificial Graſſes, this muſt in Courſe ſink the Value of the formerly ſo highly valued Hay got in the Vales.

The ſame Obſervation may be made relating to the rich Dove-Bank Lands, and ſome others in the Kingdom of the ſame Nature, which were formerly ſo famous and ſo valuable for their feeding of Cattle ſo early and ſo well, that they bore an exceſſive Price; but ſince the many very great Improvements made with and by Lime, by which many other Places are brought to feed all Sorts of Cattle very well, thoſe high-prized Dove Lands have ſeveral of them ſunk very conſiderably in their yearly Value.

But if the Northern Farmers ſhould go into the ſeveral new Improvements, as both their Lands, and their Labourers and Expence of living, are much cheaper than thoſe in the South; by ſuch a Method of Management they might be on an Equality with, or have the Advantage of the South Country Farmers. For as for their being nearer or farther from the beſt Markets, thoſe Circumſtances were always the ſame, and ſeem in general unalterable, though ſome Variations may probably be hereafter made therein, by making more Rivers navigable, or future better Contrivances of Carriages, or mending of Roads, by ſome of which I have known four Parts in five of Carriage ſaved.

Though the ſeveral Species of Corn, Graſſes, and Roots, will be ſeparately conſidered under their reſpective Titles; yet we thought the ſtating them together in the ſeveral Views above-mentioned, would guide the Reader the better and eaſier how to vary his ſeveral Crops to his greateſt Advantage, than if he was left to make ſuch Collections himſelf, which would coſt him more Pains and Thought than he will be apt to imagine; notwithſtanding which there is ſtill Room for any ſenſible judicious Reader, to make many other uſeful Variations of his Crops, than he will at firſt imagine, or than can be eaſily deſcribed.

We come now to conſider the ſeveral Sorts of Grain, Graſſes, and Roots ſeparately, and ſhall begin with the principal and moſt valuable Grain, which is Wheat.

Wheat is of ſo excellent a Nature, and of ſo general a Uſe, that it cannot be too much commended, nor ſufficiently taken Care of as to the Culture and Management of it; for which Reaſon we ſhall treat of it firſt in general, as it really is what it is frequently called, The King of Grains; and we ſhall after conſider the ſeveral Sorts of it in particular, and the Culture, Management, and Produce of it; by which the Reader will be inſtructed in the Nature of it, as it is a very curious Grain, and alſo in what relates to it in particular, as it undoubtedly is the moſt uſeful of all Grains in theſe Parts of the World; if not of all Grains in the whole World; to which Title it ſeems to have a Right to put in a very fair and juſt Claim.

Of Wheat in general.

There are three Things which chiefly make any Thing much eſteemed by, and truly valuable amongſt Men:

Firſt, The real Uſe and Benefit of it.

Secondly, The Eaſe with which it is to be acquired. And,

Laſtly, The intrinſick Excellency of its own Nature.

All which good Qualities, or Properties, Wheat is poſſeſſed of in a very eminent Degree.

As to the real Uſe of Wheat we apprehend is that which not only in general ſupports the very Life of the greateſt Part of Mankind, but alſo ſupplies us with numerous other Conveniencies to make our Lives eaſy, comfortable and happy; affording us Strength, Health and Pleaſure; being the beſt Nouriſhment, and our chief Support as to what is eatable; and alſo affording us excellent Malt for Drink, whenever it is thought proper to uſe it for that Purpoſe. It grows in almoſt all Countries, and in ſuch a Variety of Soils, that very few Places need to want it: and to uſe the learned Dr. DERHAM's Words, ſpeaking of the Bleſſings we enjoy, he ſays, "Among Grains "I might name the great Fertility of ſuch as "ſerve for Bread, the eaſy Culture and Propa-"gation thereof, and the Agreement of every "Soil and Climate to them."

As to the ſecond Article, The Eaſe with which it is to be acquired.

Two Things may properly fall under our Conſideration:

Firſt, The uſual Labour and Expence neceſſary for the obtaining a Crop of Wheat. And,

Secondly, The Quantity it generally produces.

As to the Expence and Labour neceſſary to procure it, they are ſo well known in general, that they will not deter the Farmer from endeavouring to obtain it; they being generally ſo full of the Expectation of the Profit of it, as to want no Encouragement to attempt the cultivating it: thus generally depending on the Profit of a Crop of Wheat to pay two Years Rent, and the Huſbandry neceſſary for the three Years in the old Courſe of Tillage. The Particulars neceſſary to be known in this Reſpect, will fall under Conſideration when we come to treat of the Ways and Means preparative to it. However, on a general Eſtimate, ſuppoſing two Years Rent and Accidents one Pound five; Plowings, Sowing and Reaping one Pound five; Seed and Weeding fifteen Shillings; Manuring it one Pound fifteen. This whole Expence would amount to five Pounds; and reckoning the Farmer to have but four Quarters and a

half,

half, and that to be ſold at thirty Shillings, he is paid for all his Labour, and has one Pound fifteen Shillings clear Profit; for the Straw is ſufficient to pay for the Thraſhing.

Of the Quantity of the Produce of Wheat.

If we conſider what great Quantities of Wheat have been produced both formerly and of late Years, in ſome extraordinary Inſtances; and alſo what may reaſonably be expected commonly from it, in a Courſe of good Huſbandry, on Ground proper for it; what has been before mentioned will appear a very moderate Computation of the Profits ariſing from an Acre of this Corn.

The Inſtances mention'd by Pliny of the Fertility of Wheat, are yet too remarkable to be omitted; "Nothing, ſays he, is more fruit-"ful than Wheat (which is the chief Support "of Mankind) from one Buſhel one Hun-"dred and Fifty are produced; and the Pro-"curator ſent to Augustus (which is ſcarce "to be credited) one Grain which had about "Four Hundred Stems; and another was ſent "to Nero which had Three Hundred and "Fifty."

To which I ſhall take the Liberty to add a Paragraph relating to the Uſe of Wheat, from the ingenious Dr. Derham, in the following Words:

"Among the many Contrivances for Food, "I cannot but attribute that univerſal Aliment, "Bread, to the Revelation; or, at leaſt, the "Inſpiration of the Creator, and Conſervator of "Mankind; not only becauſe it is a Food uſed "in all or moſt Parts of the World; eſpeci-"ally becauſe it is of incomparable Uſe in the "great Work of Digeſtion, greatly aſſiſting the "Ferment, or whatever cauſes the Digeſtion of "the Stomach." Of which take this Example from the noble Mr. Boyle, "The extracted "Menſtruum from Bread alone, that would "work on Bodies more compact than many "hard Minerals; nay, even on Glaſs itſelf, "and do many Things that Aqua Fortis could "not do: yet by no means was this ſo corro-"ſive a Liquor as Aqua Fortis, or as the other "Acid Menſtruums." The Way of preparing this is deliver'd in Harris's Lexicon.

We need not go ſo far backward for Inſtances of extraordinary Fertility of Wheat, ſince in our own Country, Mr. Evans, of Southampton, had from one Corn eighty Ears, containing about Four Thouſand Grains, ſome had ſixty, and ſome had ſeventy Grains; and he had on the whole about ſix and twenty Quarters on an Acre, when the Corn was ſet at ten Inches Diſtance.

Mr. Hamilton mentions, that on trying Mr. Mortimer's Receipt for ſteeping Wheat in Water, Pigeon's Dung, Nitre, &c. though but little of it appeared above Ground, what came up branched ſo, that he could number forty Stalks from one Grain; every Head was very long, and the Grain large; "I planted it, ſays "he, about ten Inches diſtant, I don't doubt if I "had given half the Seed, that I ſhould have "had a very large Crop."

There have been ſeveral Inſtances much of the ſame Nature, but not to inſiſt on theſe extraordinary Caſes; we are well aſſured of there being eight or ten Quarters or more on an Acre in Cheshire, and in other Places, on Lands well huſbanded and carefully managed. And Miller mentions eight or ten Stalks from one Corn, and eight, ten, or twelve Quarters of Wheat on an Acre as no uncommon Thing, both in his own Caſe and in that of others, which he has ſeen and obſerved.

This laſt Summer I have taken up Wheat both in Hertfordshire and Essex, with eight Stalks and under from one Corn; ſome of which had thirty odd Corns in an Ear, and ſome above forty, which ſome of the Owners had never obſerved, but then counted, and only before thought the Corn heavy: fifty to a Stalk comes to Mr. Evans's Calculation of four Thouſand for one; and at eight Stalks, forty five in an Ear, will be three Hundred and ſixty from one.

The ſeveral Calculations after mentioned, from the Grain when ſet at different Diſtances, will probably give the Reader a clearer Notion of what Produce may be reaſonably expected from an Acre of Land as differently ſown or ſet, than any Inſtances of what others have obtained will do; and therefore we ſhall only here add the Caſe of Mr. Yelverton in Ireland, who had the Reward allowed for the Perſon who ſhould produce the moſt and beſt Wheat on an Acre of Ground in that Kingdom; by which the Reader may ſee what may be gained by a proper Management of Land, in the Method that Gentleman took in the Ordering of it.

Mr. Yelverton in 1742, had the Prize in Ireland, having ſix Hundred ſixty-eight Stone and eleven Pound of Wheat off of one Acre.

The Method he took was to change his Seed; then he ſowed it not too thick; and he mowed it.

The Seed was ſteeped the Evening before the ſowing it in a Pickle, and he riddled hot dry Lime over it as uſual.

The Pickle was thus made;

Take Rock Lime and Bay Salt, put them together in a large Veſſel: then throw in a ſufficient Quantity of Urine, ſtill ſtirring them till it diſſolve the Salt, and ſlake the Lime; let them continue ſo twenty-four Hours, and then let the Liquor run out into another Veſſel for Uſe.

The Corn ſhould remain from Night to Morning in this Pickle before ſowing.

This Liquor prevents the Smut, and deſtroys a pernicious Inſect, which he calls the ſmall red Worm, often deſtructive to Seed, eſpecially in rich old Grounds.

I preſume, that in this Caſe the Lime and Bay Salt qualify the uſual Effects of the Urine, which, when uſed alone, is ſubject, as many have obſerved, to prevent the Wheat from growing. This I have alſo experienced myſelf in ſome Trials of that Kind, though at the ſame Time I have found the Seed grow when the Urine has been mixed with half Water.

After giving the Reader this general View of Wheat, and ſome particular Accounts of its Produce; we ſhall now proceed to conſider this noble

noble Grain in a more particular Manner, by tracing it from its Origin in the Seed, through the ſeveral Stages by which it paſſes to its full Maturity; and in this Courſe we ſhall endeavour to comprize whatever is neceſſary or worthy to be known relating to it; the whole of which we ſhall comprize under the following Heads:

In the firſt, We ſhall conſider the Nature and Contexture of it; with the Manner of its Growth.

Second, What Ground is proper for it.

Third, How the Ground is to be prepared to be moſt agreeable to it.

Fourth, How the Wheat is to be prepared for the Ground.

Fifth, How they are to be ordered whilſt they continue together.

And laſtly, How the Wheat is to be managed when ſeparated from the Ground.

But before we enter into the Account of its Nature and Growth, it will be proper to give a Deſcription of it, and to mention the ſeveral Sorts of it, and which of them are the moſt commonly propagated.

Wheat is an Annual Plant, tall and ſlender in the Stalk, with graſſy Leaves and a heavy Ear; the Root is fibrous, and the Stalk hollow. The Conſtruction of the Ear is this. Each Huſk is compoſed of two Leaves, or Valves, which are of an oval Form, and generally contain three Flowers. Each Flower is compoſed alſo of two Valves; the outward one belly'd, the inner flat. In this ſtand three Filaments, with little duſty Knobs ſplit at their Ends. In the Centre of theſe is placed the Rudiment of the Grain. From this riſe two Filaments, which are feather'd at the Top; theſe catch the Male Duſt that afterwards impregnates the Seed. The Seed ripens by Degrees after this, and the two Valves of the Flowers retain it till it is ſeparated by Time or Force.

The ſeveral Sorts of Wheat are;

Firſt, White or red Wheat, without Awns.

Second, Red Wheat, in ſome Places called Kentish Wheat.

Third, White Wheat.

Fourth, Red ear'd bearded Wheat.

Fifth, Cone Wheat.

Sixth, Grey Wheat, in ſome Places called duck-bill Wheat, and grey Pollard.

Seventh, Polonian Wheat.

Eighth, Many ear'd Wheat.

Ninth, Summer Wheat.

Tenth, The Wheat called naked Barley.

Eleventh, Six rowed Wheat.

Twelfth, Long ear'd Wheat.

Thirteenth, White ear'd Wheat.

Theſe are ſtrictly ſeminal Variations, not diſtinct Species; nor are ſeveral of them of any great Moment in general; but we thought it proper to mention them all in a Work of this Nature.

The firſt ſix Sorts commonly grow in England; but the firſt, the fourth and the fifth, are the beſt worth cultivating here; as being very hardy, and affording a greater Quantity of Flour than the reſt. The Cone Wheat is to be preferred to all, as having a larger Ear and fuller Grain than any other, and is the Kind moſt ſowed near London.

Some prefer the third on Account of the extreme Whiteneſs of its Ears, and ſome the bearded, as thinking it leſs ſubject to mildew; but of this there is no Certainty.

The Polonian Wheat is little cultivated now to what it was formerly; nor is there any Reaſon known why it is omitted.

The eighth is little cultivated here, though much in Italy and Sicily; ſome Stalks of it have ſeven Ears, and it has commonly three or four; which often occaſions its being laid.

The Summer Wheat is ſown in the Spring, and is ripe as ſoon as the other; but not producing ſo great a Quantity of Flour as ſome of the others, it has been neglected, tho' it may be very proper when the other miſcarries.

The tenth Sort is little cultivated, the Grain being thin, and the Flour coarſe; but it is very hardy, and will grow upon any Soil.

The ſix rowed Wheat is not very common, the Ears are but ſhort, and have each ſix Rows of Grains in them.

The twelfth Sort is cultivated in ſeveral Parts of England, and much in Wales; the Grain is pretty long, but not ſo full as ſome other Sorts, it has a greater Quantity of Chaff, and the Awns of it are as long as thoſe of Rye.

To theſe we ſhall add the following Varieties of the others:

1. Egg-ſhell Wheat; this is reckoned beſt for light Lands, and to be mixed with Rye for Maſlin, it being early ripe.

2. The Double-eared Wheat; this proſpers beſt in a heavy Clay, or a loamy Soil.

3. The Red or Kentish Wheat; this is much ſown in Hertfordshire.

4. The Great-bearded Wheat, which thrives well on a heavy Clay.

5. The white Pollard Wheat.

6. The Flaxen or Lammas Wheat.

Egg-ſhell Wheat is reckoned the beſt of all others for yielding the whiteſt Flour, and makeing the beſt of Bread; it will grow well in a loamy Earth, and in gravelly, chalky, and ſandy Loams; it ſuits light Lands beſt, and is generally early ripe.

As to Red Lammas; as Wheat is the King of Grains, ſo this has been eſteemed hitherto the King of Wheats. It grows beſt in the richeſt Vale Lands, or blue Clays, where I have ſeen it near five Foot high, yet it is ſown by many in Up-Land dry Loams, and even in ſome Gravels, that have been before dreſſed extraordinary well: and this is that noble Sort whoſe Kernels are ſomewhat longer than Perky Wheat, and near as big as Cherry-ſtones. When ſown in a right Soil, will out-weigh Perky, but turns not out ſo much Flour; it is ſix Inches taller, and ſo ſubject to fall.

Yellow Lammas has a white Straw, and a red Ear; the Flour is near as white as that of the other Lammas; it will grow on Chalks, Gravels and Clays, and other poorer Lands better than Lammas.

Perky has a white Straw, a white Ear, and a red or yellowith Kernel, more round than Lammas. It comes into Repute as it will do well in

chiltern Grounds, chalky and gravelly Soils, well dreſſed; it will do in poorer Ground, and turn out as much, and is not ſo ſubject to blight. The Vale Farmers now find that it yields more than Lammas, is hardier, and will grow in a coarſer Tilth, in a proper Soil, and will do with leſs dreſſing than Lammas. It bears late ſowing beſt, and is to be ſown after artificial Graſſes, Peaſe, Beans and Turnips with one Plowing.

White Wheat has a white Straw, and a white thick Ear; its Kernel is as big as Perks. It grows cloſer together than red Lammas, and ſo is better ſecured from Blights. It has two or three Chaffs, which ſecure it againſt Flies. It thrives well in incloſed, poor, gravelly, chalky and light loamy Soils; and is much ſown and mixed with red or yellow Lammas: it weighs lighter, but makes more Flour than the Perks or Lammas. Bakers mix them. It will grow well both in vale, ſwampy and ſtiff Soils, and in chiltern dry Grounds.

Duck-bill or Dugdale Wheat has ſeveral Names, and has a darkiſh brown guttery Kernel, rather bigger than other Wheat, the Chaff, by its Sharpneſs, hurts the Horſes Mouths. It is ſown in Vale and Chiltern Ground, in wet and dry Loams, which are made rich with Manures, for a poor Soil agrees not with it; it is bulky and ſubject to fall, but folding on it makes it ſtand.

When ſown on a fine well dreſſed Tilth, it produces a great deal of Grain; its Flour is of the coarſeſt and heavieſt Sort: it may be ſown in October, and even to February or March you may ſow any of the Pirks or white Wheats.

There are ſeveral other good Wheats in different Parts of the Kingdom, known under various Names; and ſeveral of the above-mentioned Sorts are called by different Names in various Places; and ſeveral of them are ſo mixed in ſowing, that many large Farmers are not acquainted with the diverſe ſeparate Sorts, or their proper Names: nor do I perceive there is any Objection made to their mixed Corn when brought to Bear-Key.

That called Cone Wheat is certainly a very good Sort, but the London Bakers think it too ſweet to have a great deal of it in the Flour they make their Bread of; they generally buying it in Flour, and Whiteneſs being a great Article, prefer the red Wheat, and mix them, if neceſſary. Thoſe who will not go to the Price of the beſt put in Allom, which gives the Bread a Whiteneſs, but a poor dry Taſte.

The Perſian Wheat may be mentioned as a Curioſity, it having five Heads on one Stalk, one in the Middle as long as the Ears of our Wheat, and two on each Side about an Inch long; it is raiſed ſometimes in the Gardens of the Curious: Mr. Hamilton planted ſome of it on his coldeſt Soil in Scotland, having firſt mixed unſlacked Lime with Horſe Dung prepared ſome Time before, with the Earth it was planted on, which brought it to its full Maturity.

All Farmers agree that ſome of theſe Sorts of Wheat thrive beſt on ſtrong ſtiff Land, and other Sorts do beſt on a light Soil; ſo that it behoves the Farmer to ſuit his Wheat to his Soil, or work his Soil in the beſt Manner poſſible to ſuit the Grain; and perhaps the doing this right may require the beſt Judgment and Skill of any one Article in Huſbandry.

There is frequently a great Variety of Soils in Lands lying together; nay, even in one and the ſame Cloſe at a very little Diſtance; ſandy Soils on the one Side, ſtiff Soils on the other, wet and oozy in the Middle.

After this general View of the different Sorts of Wheat, and of the Soils ſuitable to them: we ſhall proceed to treat of it in the Method before mentioned, and firſt conſider how Corn grows.

How Corn grows.

To know how Corn grows, Experiments have been made of ſeveral Grains; and Seeds of various Species have been cauſed to vegetate in the open Air, without any Aid or Aſſiſtance from the Earth.

The Seed on theſe Occaſions is laid on a light Lay of Wool, ſpread on a Plate with Holes in it; on the Mouth of a larger Veſſel filled with clear Water, and after repleniſhed with more as neceſſary, which draw up an Humidity into the Wool, that ſupplies the Place of Earth, and nouriſhes the Seeds.

I have tried the Experiment myſelf with a brown Pot full of Holes like a Cullender, placed over, or rather in a larger Veſſel near full of Water; and it is very well known that the common Warmth of the Sun raiſes a conſiderable Quantity of Wet into the Air; which, in this Caſe, muſt paſs thro' the Holes in the brown Pot, and ſo keep the Wool moiſt. And it is alſo found by the exacteſt Experiments, that all Waters ſo carried up, conveys ſome fine earthy Particles with them.

In a few Days the Wheat, Grains, and Seeds will begin to vegetate; and extend, by ſlow Degrees, their Roots towards the Water, where they imbibe, however, a leſs Quantity of Juices than they would from the Earth. Yet they will proſper in that Situation, eſpecially if the Water be frequently changed.

I have compared the Reſult of thus placing Seeds on Wool, and ſowing them in the Earth, and find their Progreſſion to be much the ſame.

When a Seed has been about two Days in the Earth, the Juices with which it is ſwelled are imparted to the Bud, and cauſe it to grow.

The Bud is always ſituated in one of the extreme Parts of the Seed, and that Part which lies neareſt the Surface is the ſmall Root of the future Plant. That on the other Hand which is next the internal Subſtance of the Seed, is its Stem and Head.

The Subſtance of all Seeds in general conſiſts of two Pieces, generally called Lobes, and which at firſt are united by one common Covering; the Structure whereof is more or leſs ſolid. Theſe after ſeparate and ſerve as ſeminal Leaves to the Plant, and then wither and decay when the Plants have no farther Occaſion for them; and theſe Obſervations may ſoon be made of divers Species of Beans and Peaſe.

The Bud of a Grain of Corn which has been lodged in the Ground, begins for the moſt Part in about four and twenty Hours, or ſomewhat more, to burſt its Foldage, and to diſengage itſelf; after that it ſhoots out its Root and Stem.

The Root at firſt is incloſed in a Sort of a Purſe, thro' which it breaks its way: two other Roots within the Space of a few Days ſhoot forth from the Sides, and each of them burſts through the Covering wherein they were infolded.

All theſe three Roots are ſhagged with a vaſt Number of Filaments, which wind themſelves about the little Clods of Earth which they meet with in their Progreſs.

By this cloſe Adheſion they draw whatever is nutrimental to the tender Plant.

As to the Stem, that ſhoots upwards in a perpendicular Line; there are ſeveral appearing Reaſons for the Deſcent of the Root, and Aſcent of the Stem offered by Writers; but there are not any two Things more unaccountable in Nature, than that of Seeds turning themſelves downward in order to ſtrike their Roots into the Earth; and the Stem aſcending directly upwards, contrary to all the Laws of Gravitation.

Corn will begin to ſhoot a ſmall verdant Point out of the Ground in five or ſix Days Time at the fartheſt after it is ſown.

This little Stem is no more than a ſmall Parcel, or Packet of Leaves folded one upon another all round the Ear; which remains for ſome conſiderable Time inviſible, and is lodged in the Heart.

Tho' the firſt Leaf of this Packet opens a little toward the Point, yet the lower Part is always confined, and rolled up in the hard Tegument from whence it ſprings.

Some few Days after, the Covering of the Seed begins to waſte away, and the Purſe wherein the Roots were contained, decays and dies away when it has performed its Offices.

When the Leaves are duly unfolded, we may plainly perceive the firſt Draught, or imperfect Sketch of four Tubes, which form the Stem; and at the Bottom we may likewiſe diſcover the Bud of the Ear.

From the firſt Knot which lies neareſt to the Roots, ſhoots out a Leaf, which performs the Function of a Covering to a ſecond Tube; at the third Knot begins another Leaf, which covers the fourth Tube and the Ear.

The Interſtice between the firſt and ſecond Knot neareſt the Roots, is then much larger than that which ſeparates the ſecond from the third.

On theſe Tubes thus jointed as it were, or ſet one into another, the Ear riſes; which may be diſtinguiſhed with Eaſe by its round tranſparent Grains, which bear the Reſemblance of ſo many little Pearls.

At length the Ear ſhoots from the Foldage which ſkreened it from the Air, and the ſeveral Bags or Lodgments which are appointed to contain the Subſtances of the future Grains, begin to be dilated.

Theſe Lodgments ſhoot out ſlender Bodies for the Reception of the Powders from the Packet of Chives, which make their Appearance above, and render the Buds prolifick.

When the Buds have dilated in thoſe Lodgments, that mealy Subſtance to which they are united by ſeveral Filaments, which may with Propriety be termed the ſeminal Roots, the Foldage and the firſt Leaves which extracted from the Earth and Air ſuch Juices as were proportioned to the delicate Structure of the Stem, begin to waſte away.

The Stem then operates more powerfully by itſelf, it exhauſts from the Leaves their nutritious Juices, with a View to enrich the Ear which it ſupports.

It is Matter of Admiration, that ſo valuable an Ear ſhould be ſupported by ſo tall and ſlender a Stem; which is deprived of all Manner of Shelter and Protection, and is planted in the Midſt of an open Field, where all the Winds have in their Turns full Power to blow it down.

This Grain often aſcends to the Height of four or five Foot from the Ground; and tho' the ſmall Stem has no more that two twelfths of an Inch for its Diameter, yet it is contrived according to the ſtricteſt Rules of good Œconomy, for by this Means a ſmall Field will contain an infinite Number of Ears.

This Stem, however, as ſlender as it appears to be, has been formed with ſuch Art and Ingenuity, that it is thereby preſerved for ſeveral Months ſucceſſively unhurt; notwithſtanding its being openly expoſed to Storms and Tempeſts, and to all the various Fluctuations of the Air.

Four Knots of a hard Subſtance reſembling the ſame Number of ſtrong Bands, make it as firm as it is neceſſary, without rendering it in the leaſt unpliant: it is flexible enough, and qualified to bow without breaking, not only under a common Gale of Wind, but even under the Shock of the moſt ſudden and impetuous Blaſts.

By the Aſſiſtance of its Knots it is enabled to recover its firſt Poſition, as ſoon as the Storm is over; and it is a very agreeable Sight to view this Foreſt of Ears under a gentle Agitation of the Wind; each ſucceſſive Breath of Air makes them bow in their Turns, and ſeem to roll along the Field like the Waves of the Ocean.

The Ear is formed with no leſs Art and Judgment than the Stem; the Grains which are in them are ranged one above another, at equal Diſtances, in order that they may receive an equal Proportion of Nouriſhment and Support. They are alſo concealed and ſecured under various Teguments, which are thick enough to break the Force of the Sun's Beams, and are ſo cloſely joined together, that they can exclude and throw off thoſe Dews and Rains which would otherwiſe oblige them to ſhoot out.

Several of theſe Teguments terminate in as many Points of different Sizes; which, as ſome imagine, are little Ducts or Channels, intended to introduce into each Lodgment a ſufficient Quantity of Air; and, according to the Opinion of others, they form a kind of Paliſade againſt the Depredation of the little Birds.

I am apt to believe that these Points, or Beards of Corn, are appointed to withstand and break the Force of those heavy Drops of Rain which fall upon them; by which Means they are discharged from each Side, and from the Surface, instead of penetrating to the Bottom of the Lodgments of the various Grains, which would putrify was the Humidity to continue among them for any Time.

The Process of Nature in the Vegetation of Plants, as exemplied in a Grain of Wheat, is as follows.

The first Day the Grain is sown it grows a little turgid, and the Husk gapes in several Places, and the Body of the Plant swells, and the Gem or Sprout opens and encreases, and the Roots begin to bunch out, and the Placenta, or Seed Leaf becoming loose gapes.

The second Day, the Secundine or Husk, being broken through, the Stem or Top of the future Straw, appears on the Outside thereof, and grows upwards.

The third Day the Pulp of the Conglobate, or round Leaf, becomes turgid with the Juice it has received, from the Earth fermenting with its own.

The Stem from whitesh turns greenish, the lateral Roots break forth greenish, and the lower Root grows longer and hairy, with many Fibres growing out of it.

Hairy Fibres hang all along on all the Roots, except on the Tops, and these Fibres wind about the Particles of Soil like Ivy, whence they grow curled; above the lateral Roots two other little ones break out.

The fourth Day the Stem, mounting upwards, makes a right Angle with the seminal Leaf, the last Roots put forth more, and the other three encreasing have more Hairs, which closely embrace the Lumps of Earth, and where they meet with any Vacuity, unite into a Kind of Network; the Leaf is now softer, and when bruised yields a white sweetish Juice, like Barley Cream.

The fifth Day the Stalk still rising puts forth a Stable Leaf, which is green and folded, the Roots grow longer, and there appears a new Tumour of a future Root; the outer Husk, or Sheath, is loosened, and the Seed Leaf begins to fade.

The sixth Day, the Stable Leaf being loosened, the Plant mounts upwards, the Sheath still cleaving round it like a Bark; and the Seed Leaf is sinuous or wrinkled, and faded.

After the eleventh Day the Seed Leaf, as yet sticking to the Plant, is crumpled and almost corrupted, within it is hollow, and about the Secundine, the Mucus and white Substance of the Seed being continued to the navel Knot, form a Cavity; all the Roots becoming longer put forth new Branches out of their Sides. The second Leaf withers, and its Vesicles are emptied; the Spaces between the Knots grow longer; new Gems appear; and the middle Root grows several Inches longer.

After a Month, the Roots and Stalk being grown much longer, new Buds break out at the first Knot, and little Tumours bunch out, which at length break out into Roots.

The Roots which grow are generally according to the Goodness of the Ground, and the Compass allowed for the Grain of Corn to extend itself in; Miller says he has traced a Root to the Extent of a Yard, which is farther than I could ever trace one; but with the Allowance which may be proportionably made for the very fine Threads, which could not be taken up. I think I have found some extend two Foot in Length or near it.

Four, five, or six Stems are what is commonly to be met with in the usual Course of Husbandry; each contain, if tolerably good, from thirty to forty Grains or upwards; as I have counted them this Summer both in Hertfordshire and Essex.

I have sometimes met with eight Stems from one Grain, in Corn sown in the common Way which is about three Hundred for one; but that is not very usual. We shall have Occasion to mention this again when we come to compare the different Produce arising from various Grounds, and from Grain sowed at different Distances, in one and the same Grounds: and therefore shall proceed to our second Head: that is,

How the Ground is to be prepared for Wheat.

This being a Point of the last Importance to the Farmer, requires a particular Consideration; especially as the New Husbandry gives a quite different Method of Management in this Matter; and more especially as some new Ways of Proceedings in this great Article have very lately been introduced, and are just now struck out by some ingenious Farmers, which I apprehend very well deserve to be set before the Reader in a proper View.

The usual Method of preparing the Ground for Wheat, was formerly by plowing it three, four, or five Times, and dunging it when necessary. This, in general, answered very well, when proper Regard was had to the Nature of the Soil, and the different Seasons which happen; since it has been found, by repeated Experience, that both Frosts and Snows have great Influence on Corn Land, both in the Respect to the necessary plowing it, and also as to the certain enriching it when the Snow falls and lies on it.

For the Frost, when to any moderate Degree, certainly lightens the Ground so much, that the usual Plowings have undoubtedly a much better Effect on it for Wheat; and when it continues any Time, it makes the last Plowing unnecessary, or indeed proper for some Sorts of Grounds, as is evident to every experienced Farmer. And Miller is of Opinion, that the Ground for many Years after the great Frost, required less Plowing than it did before.

Frost not only lightens the Earth, as before mentioned, but makes it more susceptible of the Air, which certainly not only conveys an unaccountable Quantity of rich Nourishment into the Soil; but by its working Power stills loosens and lines the Particles of it after a very extraordinary Manner; for though it may be hard to say what it is, or however difficult it may be to name or describe it, the beneficial Effects of it

are found beyond Diſpute, which are really ſo great, that ſome of our moſt judicious Writers, and beſt Farmers are of Opinion, that the great Uſe and Benefit of plowing, digging, and ſo frequently ſtirring the Ground, is principally to make it more capable of imbibing or receiving the Benefit conveyed to it by the Fertility occaſioned by the Air and Dews; the Truth of which every one may be convinced of, who will only conſider the Riches acquired by his barely fallowing his Land, without any Manure at all; and that it is common to ſee, in many Places, Land worn out with Tillage, made again proper for it, by only lying ſome Years uncultivated.

A proper Fineneſs for the tender Roots of Grain to ſtrike in, is abſolutely neceſſary; but this, in many Caſes, might be effected without many plowings.

And indeed all obſerving Perſons agree, that the Air, Rains, and Dews, are replete with great Variety of Particles which are eaſily made viſible, and which have very ſurprizing Effects both in and upon the Earth, and in and upon Vegetables.

The curious Dr. Hale found, That a cubic Inch of blue Clay being diſtilled, an hundred and eight cubic Inches of Air were raiſed from it.

This wonderful and important Fluid the Air, is found to be very operative in every Part of Nature, whether Animal, Vegetable, or Mineral.

It is well known that common Air is frequently impregnated with moſt noxious Vapours, thus the Fumes which aſcend up in the Air from fermenting Wines are very pernicious, and thoſe from burſting Brimſtone deadly.

That it is by the amphibious Property of the Air, that the main and principal Operations of Nature are carried on; for a Maſs of mutually attracting Particles, without being blended with a due Proportion of elaſting repelling ones, would, in many Caſes, ſoon coaleſce into a ſluggiſh Lump.

Mr. Boyle mentions to what a great Number of Miles an Inch of Air may be rarified, and the Force of Fire Engines are viſible now in moſt Countries.

If any Perſon has a Mind to ſee the Effect of Water expanded, he may juſt wet a Bullet Mould, and then pour in a little boiling Lead, which will fly out with prodigious Force; I have ſeen it ſtrike into a ſolid Stone, but whoever tries it muſt be careful to ſecure themſelves, and all about them, from the Danger of its flying on them, if the Hole be any way toward them.

We ſee the great Power of expanding Water, when heated in the Engine to raiſe Water by Fire; and Water with Air and other active Particles in capillary Tubes, and innumerable ſmall Veſicles, do doubtleſs act with a great Force, though expanded with no more Heat than what the Sun's Warmth gives them.

Peaſe in a Pot near full with Water, on imbibing the Water, have raiſed one Hundred Eighty-four Pound Weight laid on them; by which we may ſee the vaſt Force with which ſwelling Peaſe expand. And it is doubtleſs a conſiderable Part of the ſame, which is exerted not only in puſhing the Plume of a Plant upwards into the Air, but alſo in enabling the firſt ſhooting Radicle of the Pea, andother Grain, and all the ſubſequent under Fibres, to penetrate and ſhoot into the Earth; thoſe two very ſurpriſing Powers in Seeds and Plants which we mentioned before, and ſhall hereafter conſider.

But though we have from theſe Experiments, and from common Obſervation, many Proofs of the expanſive Force with which the fibrous Roots of Plants ſhoot; yet the leſs Reſiſtance theſe tender Shoots find, the greater Progreſs they will certainly make in equal Times.

Dr. Woodward, and others, hence juſtly obſerve (as we before hinted) that one of the moſt conſiderable Uſes of plowing, fallowing, and trenching, and of harrowing of Ground; and of mixing Lime and ſeveral other Compoſts, is to looſen and mellow the Earth, that not only the Roots may make eaſier Shoots, but there may be a freer and readier Admiſſion of the Dews, Rain, and Air, which are found to have ſuch ſurprizing beneficial Effects. For the Air has as great and expanſive a Force as Water, as is proved by many Experiments.

Notwithſtanding this general Truth, a proper Conſiſtency or Stiffneſs of the Soil, ſuitable to the Grain ſowed, muſt be preſerved; ſince otherwiſe Wheat, and ſome other Grains, will fall. To prevent this good Farmers frequently roll the Ground when neceſſary, and ſometimes fold the Wheat with Sheep, which Practice confirms the Truth and Uſe of the Obſervation.

Could we once find out what Conſiſtency or Stiffneſs each Grain requires, and the Degree and Sort of rich Nouriſhment moſt ſuitable to them reſpectively; Tillage would be managed with greater Eaſe, with much more Certainty of Succeſs, and with greater Profit.

Theſe indeed are brought in general to a tolerable Degree of Certainty, as to the Nature of Lands proper for Wheat, Beans, and ſome other Grains; and ſome general Rules of fitting Lands with proper Quantities of Marle, Lime, Chalk, Soot, and Aſhes, are pretty well aſcertained; but yet every Way there is ſtill a large Field open to the thinking Farmer, for the farther better proportioning his Manures to his Lands, than are yet known; and which vary ſo much as to make a particular Application of more or leſs, in almoſt every different Field, fit to be obſerved.

It may not be improper to caution the induſtrious Farmer, againſt over-manuring his Land with any Sort of Improvement, for when Land is made too rich, he will not meet with a good Crop of Corn, but is ſure to find a plentiful one of Straw; and this is the Reaſon why Farmers, when they are to break up rich Land, generally firſt take off the Edge of it (as they call it) by firſt ſowing it with Oats, before they ſow it with Wheat; and a very good Farmer aſſured me, that he had loſt above fifty Pounds in his younger Years, by making his Wheat Land too rich.

Marle, Lime, Chalk, and Salt, are in themſelves excellent Preparatives of the Ground for Wheat, when properly applied, as has been before mentioned; but what is peculiarly beneficial in theſe is, that they convey no Seed of

Weeds, no Inſects or perniciousVermin, nor any thing to ſour the Ground, they are brought on or mixed with, but rather help to deſtroy the Vermin, and likewiſe ſweeten as well as enrich the Soil they are brought to.

And what is equally beneficial, the Courſe of Huſbandry which theſe require, in order to procure the conſtant greateſt Profit from their Improvements, gives the Farmer an Opportunity of obtaining the continued Advantage of them, without making his Land foul, or filling it with pernicious Weeds.

Thus for Example, Clover, which is found ſuch an admirable Preparative for Wheat, requires no ſuch Culture or Manure, as will give any annual or other Weeds an Opportunity of running to Seed, and ſo propagating themſelves over the Field it is in; it may be improved oft without any Danger; but if the Farmer ſhould lay a little fine Dung on it at Michaelmas or in February, yet the Clover being almoſt perpetually mowed firſt, either for Seed or Graſs, that early mowing will cut off any Weeds which may get in it, before they can Seed. And as the Tops of Clover are generally large and flouriſhing, ſo they over-ſhadow and keep down the Weeds; and if any Sourneſs ſhould be conveyed by ſuch a Manure, the Clover Tops, and deep Roots, will mellow it before it is plowed up for Wheat, for which one plowing is commonly ſufficient.

Much the ſame may be ſaid of Turnips, another excellent Enricher of the Ground, and Preparative for Corn, whoſe large Head over-ſhadows and keeps under Weeds; and the repeated Hoeings neceſſary in the Management of them, clear the Ground exceeding well from all Weeds and Trumpery, at the ſame Time that their large Roots are ſold to great Profit, or prodigiouſly enrich the Soil, and frequently anſwer both thoſe Purpoſes.

A ſenſible Farmer of my Acquaintance, ſowed Turnips on his Heap of Dung and Soil, ſolely with a View to keep down the Weeds, not with any Expectation of Profit from the Turnips, though, on our taſting them this October, when of the Size of a large Apple, they were pretty good, and not ſo ſtrong as we expected them to be.

Beans and Peaſe are alſo excellent Preparatives for Wheat: a good Crop of Wheat is generally depended on after a good one of Peaſe.

And here I cannot omit to mention a very extraordinary Inſtance of a new Improvement in the Courſe of Huſbandry, begun by a Farmer near Chelsea, this Spring.

He ſowed his Ground with Peaſe in Rows as uſual, and as near as I can gueſs, by what remained of the Turnips, at about twenty Inches diſtance; and when the Peaſe were grown up a little, he ſowed the Interſtices betwixt them with Turnips, and after, as I was informed, let the Peaſe reſt on the Tops of the Turnips; he after reaped the Peaſe, and ſold Part of the Turnips, and on the twenty-ſecond of this October I ſaw two Teams plowing this Ground; one of which, with ſix Horſes drawn double, plowed up a Furrow of eleven Inches deep, and twelve broad; and the other, with two Horſes, followed and plowed the Rubbiſh about two Inches deep, turning it, and all the remaining Turnips, into the Bottom of the great Furrow.

Many of the Turnips plowed in were very large, and few leſs than the largeſt Apples; the Servants told me their Maſter thought the Turnips would be as good as half a Mucking, and that he intended to ſow it as it now lay, and then to harrow it; there was no Appearance of any Rubbiſh on the Top of all that was finiſhed by the Plows.

What the Succeſs may be cannot be foretold, but in this Procedure, there appears all the ſubſtantial Benefit of Horſehoeing, as well as of giving the Wheat that Diſtance, which we are promiſed will procure us ſuch advantageous Crops; the Furrows being a Foot diſtant from each other, betwixt which moſt of the Corn will fall, after whatever Manner it is ſowed.

However, from this Experiment, a judicious Farmer may eaſily take ſeveral Hints which may be of great Service, in a Variety of other Articles.

Lentils, and ſeveral other Grains and Graſſes, are very good Preparatives for Wheat, when plowed into the Ground, or eaten on it, which different Farmers order according to their different Inclinations; and all may be of Uſe for Wheat, as will be particularly mentioned when theſe ſeveral Articles come to be ſeparately conſidered: but Wheat does not love to follow common Barley, as it makes the Land too light for it, and alſo takes too much of its Goodneſs from it: it ſeldom does well after it, though the Ground be in good Heart.

I ſhall mention but one Article more under this Head, which is that of plowing, and this having been copiouſly treated of before, I ſhall ſay no more of it than what ſeems abſolutely neceſſary and requiſite to inform the Reader, of what I apprehend an almoſt new Method of managing this Sort of Grain.

The Herefordshire Farmers generally plow five Times for Wheat, and ſhallower or deeper as Occaſion requires: and all agree it is improper to plow in Rain or Snow.

The Mode of plowing ought to be varied according to the Nature of the Soil, and the early or late ſowing. And it is a common Saying, Sow early and have Corn, Sow late and have Straw.

There is another common Rule ſaid to be a ſtanding one in Huſbandry, viz. The more Thoroughs the greater the Crops; which may be admitted as far as the Soil is more broke, and made finer by that Means. But if it occaſion the Seeds to fall cloſer to each other, ſo far it diſagrees with the modern Method of ſowing leſs Seed, and at a much greater Diſtance than is uſually done, which is now ſo much preferred to all other Ways.

About Dunstable they plow much in Stitches; and in Essex ſome very good Farmers practiſe this Method with very great Succeſs; making five Stitches when they come to ſow, which five make a Perch, ſo that between every two Stitches ther is a Thorough a Foot wide.

They ſow theſe Stitches length-ways by hand, and a Perſon uſed to it will ſow for two Teams, each

each of which plows an Acre and an half a Day; and when they have done the neceſſary Plowings, they run a ſmall Plow drawn by a ſingle Horſe, along every Thorough, which caſts the fine Mould and Corn each Way on the Stitch, and leaves the Thorough clean.

By this Method, and the ſowing ſparingly, they apprehend they have all the Advantages that are promiſed by the Drill Plow; and the Benefit of their Wheat having ſufficient Room for its Growth, eſpecially as there are ſo great Spaces left at each Side of the Stitches.

Pliny mentions the plowing Ground eleven Times, which is thought very ſtrange; but there are two very good Farmers who have ſeveral Times plowed their Ground as often: and as ſoon as the Ground is cleared from the Corn, conſtantly apply the Plow to it, and repeat it every Fortnight or three Weeks, whilſt the Weather will allow, in order to give the Earth the Benefit of the Sun, Air and Dews; and to extirpate and prevent the Growth of Weeds, which grow beſt at this Time; and by this repeated Huſbandry have cleared their Ground ſo well from Weeds, that I this Year ſaw Fields of Wheat without a Weed in the Sheaves, or one growing in the Field that I could obſerve; and one led his Wheat immediately after it was ſhorn. And by this Method they never have any Smut or blighted Corn, though one of them uſes no ſteeping: and the Land is ſo mellow, that two Horſes and a Man plow an Acre and a half a Day with great Eaſe; ſo that in Reality, they have no more Trouble than thoſe who plow leſs with ſtronger Teams, and a Boy to drive.

How the Wheat is to be prepared for the Ground.

Under this Head there are two Things to be principally regarded:

The firſt is, what Sort of Seed is to be procured; and what Quantity of it is neceſſary.

And next, how that Seed is to be ordered.

As to the firſt, the uſual Allowance for Wheat has been named already; whoever approves of the Drill Way of ſowing, ought to approve of ſowing leſs Seed than is commonly allowed to an Acre; as it comes nearer in Appearance to the Drill Method of Huſbandry, which allows the greater Advantages to the Seed of more Room for the Sun, Air, Dews, and Rain; and greater Compaſs to ſpread their Roots in the Earth, which are the principal Benefits propoſed to be obtained by the Drill Huſbandry, except the ſaving of ſome Seed; which, in this Reſpect, is comparatively of no great Value. But in the common Way of ſowing, ſome Regard is to be had to the Time, ſince a Peck leſs will do in September than after; and a Peck more than common is required in gravelly, and new broken up Grounds: and certainly great Allowances muſt be made in ſome Places for the Damage done by Vermin, which frequently devour or carry off the Seed, whilſt others are ſpoiled by lying expoſed to the Severity of the Weather.

The ſucceeding Calculations of what Produce may reaſonably be expected from Wheat ſowed at ſeveral Diſtances, may probably give the Reader ſo clear a Notion of this Matter, as to guide him in his Conduct, as to the common or different Method of ſowing his Corn.

But why may not Wheat be hoed at ſuch Diſtances as the Owner pleaſes, as well as Turnips? Is not the ſame Reaſon that ſatisfies us of the Prudence of our Conduct in the one, as ſtrong and forcible in the other? The Farmer before named ſpoke of hoeing his Wheat as well as his Turnips, but has not yet ventured to cut up what I would call the ſuperfluous Wheat; though he finds the hoeing it not only to anſwer as to the clearing off the Weeds, but alſo as to looſening the Surface, and refreſhing the Wheat: but ſure the hoeing Wheat to eight or nine Inches Diſtance, could be no Hazard of making it too thin; and this near the Thoroughs would anſwer the Diſtances propoſed by thoſe who ſeem deſirous to allow the largeſt Compaſs of ten or twelve Inches to ſpread in.

But why might not the ſpare Wheat in one Place be tranſplanted to Vacancies, which frequently happen in others, or even to freſh Ground prepared for it?

A good Hand with a Trowel would tranſplant ſeveral Hundreds in leſs Time, and at a leſs Expence than moſt Readers would imagine; and Wheat may certainly be tranſplanted very well: I name a Trowel becauſe that when it opens the Ground for the Wheat, hardens not the Sides of the Holes as ſetting Sticks do, but leaves the Earth looſer for the Wheat Root to ſtrike freſh in.

Every Farmer knows Wheat will bear cutting down occaſionally, or mowing at proper Seaſons without any Prejudice to it. It is as publickly known that it will bear trampling on by Sheep, when folded properly upon it; and the Roller is frequently alſo uſefully applied to it; and I know it will bear being tranſplanted, and if prudently done at a proper Seaſon, and in Ground ſuitable for it, a Man would preſently tranſplant an Acre at a Foot Diſtance: the Hazard could not be great, and the Profit of its ſucceeding would be very conſiderable. Or the Trial may be made on a leſs Parcel of Land, and on ſuch which the Farmer might not before have had Time to order to his own Satisfaction.

As to the Choice of proper Seed Wheat, there are very few who have that Care in this Particular which they ought to have; for much more certainly depends on good and proper Seed, than moſt Perſons think.

Corn growing on Virgin Mould (as called) or new broken up Ground, is generally allowed to be beſt of all; and where that cannot conveniently be had, it is very adviſeable to get Seed from ſome diſtant Place at leaſt once in two Years; or if from Land in the ſame Neighbourhood, let it be from different Sort of Land.

Mr. Yelverton who gained the Reward in Ireland for getting the beſt and moſt Wheat there, had his Seed from England; but whereſoever the Seed is taken or brought from, take particular Care that it be perfectly clean and ſweet. And it is generally agreed, that the largeſt and faireſt of the Sort ſhould be choſen for Seed; as uſually producing the moſt, the largeſt, and the beſt Ears of Corn: which Rule

gene-

generally holds good both in Grain, Roots, Vegetables, and Trees, as well as in Animals; all which commonly partake pretty much of the Parent Seed.

Another conſiderable Article is the making the Seed perfectly clean from Seeds of Weeds, and Filth of all Sorts, as well as from bad Grains. And in this Caſe a little comparative Pains at firſt, will ſave a great deal of Trouble afterwards, both as to the keeping the Ground ſweet and clear from Weeds, as well as from bad and ſmutty Corn: and this, whether it be ſowed dry, or firſt brined or ſteeped in ſome Compoſition, which is now the moſt uſual Method in managing Seed Wheat, and ſhould in courſe be next conſidered.

Of brining or ſteeping Seed Wheat.

As this relates not only to Seed Wheat, but to many other Sorts of Grain and Vegetables, we ſhall give it a diſtinct Conſideration after we have concluded the Subject of Wheat; and only mention ſome ſingular Receipts recommended particularly for the improving of this Species.

We before mentioned the Compoſition uſed by Mr. Yelverton; and ſhall mention that uſed by Colonel Plummer. But as to the many Compoſitions which have been much cried up, and ſold at a great Price; they have ſeldom given any great Satisfaction, or procured the deſired Succeſs; ſo that we ſhall take no particular Notice of them.

Colonel Plummer *of* Hertfordshire, *Way of ſteeping Wheat.*

Firſt waſh the Wheat through three or four ſeveral Waters, ſtirring it well each Time, and ſkim off the light Grains.

Put Water in a Tub with a Tap, with as much Salt as will make an Egg ſwim; then add as much more; ſtir it very well, and put in two or three Pounds of Allom beat fine, and ſtir it well.

Uſe it as ordinary Brines, only ſteep the Wheat thirty or forty Hours; for leſs ſignifies nothing.

Take the Wheat out the Night before you ſow it, and ſift ſome ſlaked Lime on it. And add freſh Quantities of the Ingredients as wanted.

Mr. Bradley obſerves, That many Farmers ſteep their Wheat in Brine, yet have ſmutty Wheat, becauſe they do not make their Brine ſtrong enough; or take their Wheat out too ſoon.

A late Writer directs to ſteep the Seed in Rain Water, in which Bay Salt is mixed, till it will bear an Egg, for thirty Hours; and after to ſpread it on a Floor, with fine Lime mixed with it, and ſtirred together ſtill each Seed leaves clinging to another, and till it ſeems candy'd with Lime; and then, he ſays, doubt not the Increaſe of your Harveſt.

There are great Variety of other Receipts given to the ſame Purpoſe; and that which Mr. Ellis ſeems to value himſelf much upon, mentions the diſſolving three Pounds of Copperas in two or three Gallons of ſcalding Water; ſtir it till it is diſſolved; and, when juſt warm, pour it over two or three Buſhels of Wheat. A Quarter of an Hour after pour over all the Wheat Seed, as much mudgel-hole Water as will make the whole ſwim four Inches; and ſtirring it ſufficiently, you may ſkim off all the Seeds of Weeds, and the light Corns that occaſion Smut and Pepper Wheat.

The Seed is to lie in this Liquor twelve Hours, or it wanted ſix, or four, or two Hours; then draw all clear off, and lime it directly for ſowing the ſame Morning; but if the Seed lay and drained twelve Hours firſt, it would be better.

Care muſt be taken, that if it be not ſowed ſoon, that it be not left to lie long thick together, which ſeems agreed on all Hands to be prejudicial.

The Reader will find ſome Remarks on theſe Receipts hereafter, when ſteeping in general comes to be conſidered.

Of ſowing Wheat.

This having been treated of before, I ſhall here only give ſome additional Particulars.

The Time for ſowing Wheat in general, is from the Middle of September to the Beginning of December; but ſome Sorts of Wheats, and upon ſome particular Occaſions others may be ſowed at different Seaſons, as was mentioned when the different Sorts of Wheats were deſcribed.

But in general great regard is to be had to the Nature of the Land, and the Weather; for though dry Land may be ſowed with Care in moiſt Weathers (tho' not in wet, if it can well be avoided) yet ſtiff wet Land is only to be ſowed in a favourable Time, for fear of the Seed being loſt by the Ground's binding, or burſt, as it may ſometimes happen: but the laſt may, I think, be avoided with a little Care; as will be mentioned when we come to treat of Steeping.

But it is generally agreed to be much the beſt to ſow the Seed in freſh Mould, and for that Reaſon they commonly ſow as ſoon as ever the Ground is made ready to receive it.

The ſowing the broad Caſt way is very well known; but the ſowing of Wheat by Hand, ſowing or ſpraining the Seed in along the Stitches, as was before mentioned, and as they frequently ſprain in Peaſe, is not ſo common; though this latter Manner ſeems to come the neareſt ſetting in Rows; or ſowing according to the Drill Manner of Huſbandry.

The next Thing to be conſidered is,

How the Wheat and the Ground are to be ordered whilſt they are together.

Now the firſt Care here ſeems to be, to get all the croſs Gutters and Thoroughs well cleanſed, and the looſe Mould and Corn in them caſt upon the plowed Ground; for which Purpoſe a ſmall Plough is uſed in ſeveral Places, which is eaſily drawn by any Horſe, and contrived to throw the looſe Mould and Corn on both Sides, and leave the Thoroughs perfectly clear and ſmooth to let the Water run off.

After this there ſeems three Things neceſſary to be conſidered under this Head:

Firſt, What is to be done when the Wheat

is too forward or rank, which would endanger its being laid and ſpoiled.

Second, What is to be done when it is too poor, and wants ſome Aſſiſtance. And,

Laſtly, The great Article of keeping it clean from Weeds, which is commonly the Effect of bad Huſbandry; and often the natural Conſequence of manuring the Land with mixed Dung full of young Weeds, or with the Seeds of Weeds, which ſoon ſpring and ſpread; and which the Farmer will find it difficult to keep down, and a Work of Years to extirpate. Indeed this is a Calamity the beſt Huſbandmen often ſuffer by; ſince it is evident that the Seeds of Weeds are frequently carried by Winds and by Birds; and often lie concealed for Years in the Soil, and ſprout up on the Ground being plowed deeper than common, or near to the Hedges.

When the Wheat is too rank, it is ſometimes thought proper to mow, ſometimes to eat it, and ſometimes to feed and fold Sheep on it, as the particular Circumſtances require; which laſt is not only an Advantage ſometimes this Way, but alſo for the improving the Ground when it wants, not only by the Dung and Urine of the Sheep, but by the fining of the Mould by their treading it with their little Feet; and the Nouriſhment conveyed by the Warmth of their Bodies lying on the Ground. Which two laſt material Articles ſeem quite overlooked, or at leaſt very little regarded by ſome of our late Writers.

As to the Article of refreſhing the Ground when too poor, by ſome additional Improvement. The folding, when proper, anſwers that End very well; and, in other Caſes, the ſprinkling on a few Buſhels of Soot, Malt, Duſt, Pigeons Dung; or any Thing of that Kind will anſwer the End deſired, or even fine Mould or Dung mellowed; eſpecially if the Wheat be hoed as before mentioned, which alone would anſwer the End of refreſhing the Wheat very much, as well as help to keep down the Weeds; which is the great Difficulty the Farmer has to ſtruggle with, and which I come now to conſider.

Of weeding of Corn.

Weeding the growing Corn carefully in the common Way, by cutting them up, or drawing them where it can be done without Prejudice to the Wheat, helps to make the Ground ſweet and clean, gives the Grain more Room to grow, and to receive the Benefit of the refreſhing Air, the kindly Warmth of the Sun, the fertilizing Dews and Rains. And further, it makes the reaping the Corn eaſier and cheaper, and ſaves a great deal of future Trouble in every Article; from the cutting to the carrying it to the Market, and even in the ſelling it: ſo that it behoves every prudent Farmer to be careful in this Particular.

This is neceſſary to be done, and will be a pretty ſure preſent Remedy, as it will keep down the Weeds, and prevent their running to ſeeding, and filling the Ground with a future Crop. But this is only a temporary Help, and not an effectual Remedy, as not reaching the Root of the Diſtemper, which lies much deeper.

We before mentioned the Benefit of hoeing of Wheat, and this Summer I ſaw the Advantage of it, when performed with a ſmall Hoe, and a ſkilful Hand: for this not only cuts the Weeds, but deſtroys moſt of the Roots, ſo that all Annuals were deſtroyed; and thoſe of a more laſting Nature, prevented from doing any more Miſchief this Seaſon: the Fruit of this hoeing was, I ſaw not one Weed in a whole Field of Wheat this Seaſon, at the Reaping.

But the Reader muſt not expect the ſame Succeſs on one Hoeing, or Weeding; ſince this Farmer had for ſome Years induſtriouſly extirpated all Weeds, and carefully avoided every Thing which he thought could occaſion their Growth; ſuch as the carrying Dung with Weeds in it to the Ground, &c. Notwithſtanding which Care, he frequently obſerved a new Growth of Weeds when he plowed deeper than uſual, or near the Hedges; and thought the ſmall Seeds of Weeds were brought by the Winds and Birds, and often lodged in the Cracks of the Earth, occaſioned by Heat, or in other Places of the ſame Nature.

Theſe Remarks of this ſenſible Farmer are exactly conformable to the Obſervations of the late Mr. Ray, and other ingenious Writers, who obſerve, That many Seeds will grow when kept ſeveral Years, and moſt when kept more than one; and that ſeveral Sorts had been kept fourteen Years, and ſome buried ſo long in the Ground, and yet grew when brought again into the open Air and ſowed.

Theſe Remarks will probably give the Farmer a further Inſight into the Origin of Weeds, than he might before think of; and put him on carrying his Thoughts further, in order to obtain a proper Remedy for the Diſeaſe.

This can be no otherwiſe procured than by conſidering, that there are two Sorts of Weeds, thoſe called Annuals, and thoſe Perennials, or which laſt ſeveral Years.

The Annual Weeds will be pretty eaſily managed, if Care be taken to prevent their ſeeding both in and about the Ground deſigned to be kept clear from them. And alſo, by watching the Compoſts laid on ſuch Grounds, that they are not full of ſuch Weeds, or with the Seeds of them, which will immediately grow in the Field; and muſt then be deſtroyed there by frequently ſtirring the Ground, and turning them to the Heat of the Sun, or Severity of Froſts, or other Ways extirpating them before they ſeed, whenever they appear.

Formerly it was cuſtomary to throw up Gravel Walks in Winter, in order to deſtroy Weeds, but the doing it in the Heat of Summer is now found more effectual: and there is the ſame Reaſon for, and will be the ſame Benefit in plowing, or ſtirring up Lands, in order to deſtroy Weeds in the greateſt Heats, which will generally deſtroy both Seed and Root.

I preſume, the ſo frequently ſtirring and turning the numerous Compoſts now to be met with on every Road; is not only to mix them well together, but to prevent the Growth of Weeds in them.

As to the Perennial, or laſting Weeds, the ſame Methods will in a great Meaſure procure

the ſame preſent Advantage; but as they will grow again, and many of them will ſpread how oft ſoever they are cut down. There is no effectual Remedy, but the extirpating them by eradicating by a common Dock Spade, uſed for drawing up Docks, or deſtroying them by expoſing them to the Heat of the Sun, or Severity of the Cold, the former of which is the moſt effectual; or elſe by harrowing them off on plowing, and then burning them, as I lately ſaw practiſed near Chelsea, with twitch Graſs.

In ſome particular Caſes other Remedies may be applied, for I have known Salt Brine in Cheshire poured on Walks to deſtroy Weeds, and am aſſured ſcalding Water will take the ſame Effect.

Where Salt Water is near it may be properly applied for this Purpoſe, eſpecially for deſtroying of Weeds on Dunghills or Compoſts, but Care muſt be taken not to apply too much, for fear of the over-ſalting it, and preventing the Growth of the Corn or Graſs for ſome time; a proper Proportion of which I cannot aſcertain, though I have ſome Experiments now depending for that Purpoſe; but think the Farmer may very ſafely pour an Hogſhead of Sea Water, or more, on every ſuch Quantity of Manure he deſigns for an Acre of Land, which I preſume will help to kill the Weeds on the Dung or Compoſt, and alſo enrich the Ground when it is ſpread with the Manure.

We before mentioned the Advantage of uſing ſuch Manures as Marle, Chalk, Lime, &c. in reſpect to this Article of Weeds, as not conveying any of them to the Ground; and alſo touched on the Benefit of the artificial Graſſes and Turnips, on Account of their giving the Farmer an Opportunity of laying his Dung on the Ground, and at the ſame time either preventing the Growth of the Weeds which might be in them, or giving him a very good Opportunity of deſtroying them before the Time Corn comes to be ſowed on that Land, by the uſual Courſe of the new Huſbandry.

Where the Corn is ſowed in Drills at a proper Diſtance, it will not be difficult to clean it from Weeds by the hoeing Inſtruments; but great Care muſt be taken, that the Weeds are toſs'd, or laid ſo that they grow not again, which they will be very ſubject to do, if they are trod on when cut, or not laid light on the Ground, free from Soil adhering to them.

How the Wheat is to be managed when ſeparated from the Ground.

Here it will be proper to mention the different Methods of managing the Corn whilſt in the Field, uſed by the North and South Country Farmers, with their reſpective Reaſons for their reſpective Conduct.

In the North Counties, at the Evening, they generally ſet up about eight Sheaves, cloſe in two Rows, and then cover them with two large Sheaves half opened, and drawn over the Tops of the others, which ſhelter the whole like a thatched Cover, and will protect all for ten or twelve Days or longer, againſt all uſual Weather; and in Caſe of exceſſive Rains the wet Sides of the two Covers will ſuffer, but very rarely any other; and it muſt be a continued long Series of very ill Weather, if the Farmer has not an Opportunity of houſing his Corn well.

In the South they ſet up twelve or twenty Sheaves in two Rows, without any Cover, which they ſay helps to whiten the Wheat, but if any violent Rain or Wet happen, all their Corn ſuffers extreamly.

Where the Corn is very dry and clean, I have ſeen it carried away as ſhorn; but the more uſual Method in both Parts of the Kingdom, is to let it ſtand ſome time in the Field to ſweeten it, and make it whiter, and to ripen any Part which wants a little Weather, and alſo to kill any Graſs or Weeds which may be yet amongſt the Corn, and which may be prejudicial to it when in the Barn.

But however different the Sentiments of the Farmers may be, in the Particular above-mentioned, all good ones agree, that it is wrong to houſe the Corn too ſoon; and better to err rather in the other Extreme, it being almoſt a Proverb, "It is better to ſpoil Corn in the Field than in "the Barn."

The next Thing is the mowing it cloſe in the Barn, or ſetting it on a Stack out of Doors; in both which Caſes it is difficult to guard againſt Vermin, though ſome are very dextrous in what they call Mowing the Mouſe out of the Barn: but the ſetting it on Poſts, or Stones capped with others, which reach over the firſt on every Side, is generally found the beſt, and then Corn may ſtand ſeveral Years ſweet and good. And in ſome Parts of Staffordshire, and ſome other Places, they make their Stacks round, a Circle being the moſt capacious of all Figures, and the moſt ſecure againſt boiſterous Storms and Winds, breaking the Force of them gradually; whereas the ſquare ones receive the full Force of the Wind and Wet, and all the Inconveniencies attending them.

But however careful the Farmer may be, Mice will ſometimes get into his Stock by one Stratagem or other, and are frequently carried in the Sheaves out of the Field, and are ſoon of very ill Conſequence. It may be known if they are there, by thruſting an Aſh Pole, or Poles, pretty far into the Stack, which the Mice will eat the Bark of if they be there, as may be ſeen when they are drawn out again; for it is well known that Mice will eat the Bark of the Branches of ſeveral Trees, and the tenderer the Bark the greater the Temptation, and the eaſier it is done.

The immediate thatching, or otherwiſe ſecureing the Stacks till thatched, is certainly very expedient; and often delayed in Harveſt to the conſiderable Prejudice of the Farmer, which might be eaſily, in a great Meaſure, prevented at a little Expence, by moveable Covers, as was formerly mentioned.

The Price of thatching, where Labourers have One and Six-pence per Day for doing the whole, is uſually Ten-pence for an hundred ſquare Foot.

Threſhing is the next Thing to be conſidered, which is generally performed the beſt and eaſieſt in warm dry Weather, or in Froſt; for notwithſtanding the Barns are kept as cloſe as poſſible, the Grain is found to quit the Huſk the beſt in

thoſe Seaſons, which ſhews what Influence the Weather has, even in this Caſe, where it would not be expected to occaſion any ſenſible Alteration.

The common Price for threſhing, cleaning, and putting Wheat into the Sacks, is two Shillings per Quarter, where the Labourer's Wages are Fourteen-pence per Day at that Seaſon, and muſt be proportionably leſs where Wages are leſs. But good or bad Corn makes a Difference as to the Work, and will have its Influence on the Wages. And ſo will the Quantity of Grain in the Ears, ſome having above Forty, ſome about Thirty, and ſo on; and here Care muſt be taken, that the Corn be not damaged, when threſhed by lying on a damp Floor too long, before it is cleaned or carried off.

There is a wide Difference even in the Article of cleaning Corn between the South and North Country Farmers; the former cleaning it by caſting in the Barn, from one End of it to the other, the beſt flying fartheſt, and then ſeparateing and cleaning it again after, by the Wheat Ridler, or Fans; whereas the North Country Farmers perform this by Wind, which generally does it very well, and in defect of that have a Fan with Sails, turning on an Axis, which does the Buſineſs effectually; and even is allowed the Preference by Mr. Ellis, notwithſtanding his Partiality for the Hertfordshire Farmers. But to do the South Country Method Juſtice, a Man and a Boy will clean more than five and twenty Buſhels in a Day, as that Author mentions, ſo that he miſtakes in this Point.

The next Thing to be done is to ſend the Corn to the Market, if the Price be agreeable, or to keep it in hopes of a better, the former Method muſt in general be taken; but where any Perſon is of Ability, and has an Opportunity of keeping Corn when it is cheap, by this he has a fair Proſpect of promoting his own private Intereſt; Corn generally bearing double the Price if any one Crop miſcarries, which it generally does once in four or five Years. It is well known that the Dutch have frequently bought our Corn, and ſold it again to us at double the Price, to the great Diſadvantage of the Nation, by not ſaving it themſelves.

So that, in Reality, he who ſaves Corn in plentiful Years, may be called a publick Benefactor, as really promoting the publick Good. For it has often been lamented, by wiſe and good Men, that we have no Publick Granaries, to ſupply us in a Time of Scarcity: which all wiſe Nations, and good Governors ſhould take particular Care of.

The Countries moſt famous for abounding in Corn, were Thrace, Sardinia, Sicily, Egypt, and Africa.

When Augustus had reduced Egypt to a Roman Province, he took peculiar Care of the Bed and Canals of the Nile, which by Degrees had been much clogged with Mud, through the Neglect of the Kings of Egypt, and cauſed them to be cleaned by the Roman Troops whom he left there. From thence came regularly every Year, twenty Millions of Buſhels of Wheat. Without this Supply the Capital of the World was in danger of periſhing by Famine.

When the Emperor Severus died, there was Corn in the publick Magazines for ſeven Years, expending daily ſeventy-five Thouſand Buſhels, that is to ſay, Bread for ſix hundred thouſand Men.

What a Proviſion was this againſt the Dearth of any future Years!

Constantinople was ſupplied in the ſame wiſe Manner as Rome was, when the Empire was fixed there; and an admirable Order was obſerved in both thoſe Cities, for the Subſiſtence of the immenſe Number of Inhabitants.

The Emperor Constantine cauſed almoſt fourſcore thouſand Buſhels of Corn, which came from Alexandria, to be diſtributed daily at Constantinople: this was for the Subſiſtence of ſix hundred and forty thouſand Men; the Roman Buſhel ſerving only eight Men.

To give a later Inſtance of the Effect of Magazines of Corn, after the fatal Battle to the French at Blenheim, the French Generals waited on the King, with an Intent to get his Directions how to recruit their Forces, none of them venturing to name the great Diſtreſs they were in. The King aſked if his publick Magazines for his Soldiers were full, and being anſwered in the Affirmative, he ordered them to take particular Care that they were kept ſo. And ſoon after they found the Effects of that Proviſion, for there being a Scarcity in general, and good Proviſions made for the Soldiers, the Army was effectually ſupplied with Soldiers without any Compulſion.

Theſe Inſtances will both convince us of the Wiſdom of keeping of Corn, and alſo that it is poſſible to do it for many Years, which is next to be conſidered.

Of the Methods of keeping of Corn.

There are various Methods of preſerving Corn, which may be conſidered either as they relate to publick Granaries or Magazines, or as they concern and are the Property of private Perſons; and as there is at preſent no Appointment of the former with us, I ſhall only juſt mention two or three Particulars about them; and then come to what is within the Compaſs of private Perſons, and what may be of Advantage to thoſe who are deſirous to promote their own and the publick Good at the ſame Time.

Varro aſſures us that Corn would keep good for fifty Years, when ſhut up cloſe in the Ear in ſubterranean Caverns, which they covered on all Sides with Straw, to defend it againſt Damps, cloſing the Entrance with great Care, to prevent the Air from getting in.

This Method of preſerving Corn in the Ear is ſtill practiſed, when Corn is to be ſent to far diſtant Places. And it is ſent after this Manner to America, in Caſks perfectly well ſtopt up, otherwiſe the Subſtance will evaporate, and the Plantation of it prove ineffectual.

Another Method is to clean and dry it well, and remove it once in fifteen or ſixteen Days, for half a Year; and if it is laid up dry it will need little more Care.

After two Years good Preſervation it may be kept forty, fifty, or a hundred Years, by lodging it in Pits which are covered with ſtrong Planks well

joined together; or which is a more ſecure Method, by covering the Surface of the Heap with a ſmall Quantity of Quick-lime, and then diſſolving it again by ſprinkling ſome Water upon it with Prudence and Precaution. This Quick-lime will cauſe the Grain to ſhoot two or three Fingers in Depth, and form a Surface or Incruſtation, which is too ſtrong to be penetrated either by the Air, or any rapacious Inſects whatſoever.

In ſome Cities Abroad they have proper Receptacles for preſerving Corn in the Town Walls, particularly at Leghorn, which being cloſe ſtopped, kill all Weaſles, and keep the Corn good.

There are ſeveral other Methods preſcribed for preſerving large Quantities of Corn; but as there is no Probability of reducing them into practice here, it will be no Advantage to repeat them. But the Reader, no doubt, will obſerve that the ſame Methods directed for the keeping of large Quantities, may be made uſe of to preſerve leſs.

But as to preſerving ſmall Quantities for four or five Years, which, in general, is long enough for private Perſons in this our Country; the keeping Corn in a Stack ſet upon wooden Poſts or Stones, with Caps over them to prevent Mice getting into them, have been frequently found abundantly ſufficient to anſwer both the propoſed Ends; the preſerving the Corn good, and the bringing in great Profit to the Owner.

And if it ſhould be found convenient to take away that Stack, and place another on the ſame Poſts whilſt Corn continued cheap, there would be no Loſs any more than the diſpoſing of the Stack yearly.

And as to the Objection of the Farmer's wanting the Straw for his Ground, and the Chaff for his Horſes, as mentioned by a late Syſtem Writer; theſe are Conſiderations too trifling to be ſet in Compariſon with the Advantages propoſed by the keeping of Corn, eſpecially in Corn Countries, in which the Straw is little valued in plentiful Years, and the Chaff often entirely diſregarded.

It is common with many Farmers to keep a deal of Corn ſafe in Bags, and a great Quantity may be ſecured ſo in Hair Bags in a little Compaſs, and placed ſo that Cats may alſo keep the Place clean, if kept in common Sacks.

About Hempsted they put five Buſhels in a Sack, which is above three hundred Weight, which ſtrong Fellows are hired to carry up into the Repoſitories; though the Cuſtom is a very bad one, and often attended with very prejudicial Conſequences to thoſe who carry them, as has been the Caſe of ſome I know.

Where full Sacks are uſed in Rooms or Granaries, I have obſerved a very commodious little Machine uſed for conveying them from Place to Place, by which I have ſeen near twenty Quarters of Corn delivered out with great Eaſe in a very few Minutes. And as it is very uſeful in this Particular, and may be eaſily improved for ſeveral other Uſes, I ſhall deſcribe it hereafter.

Some place their Wheat, when threſhed, in the Chaff, in the Midſt of a Stack of Corn in which it will lie in a comparative little Compaſs.

But the moſt effectual Method is to have a Granary raiſed on Poſts, or Stones capped, as before deſcribed, for Corn Stacks: which, if contrived as the Malt-houſes are, with ſeveral Floors, the Corn may be eaſily removed, when neceſſary, from one to another, readily downward; and, by proper Pullies, with no great Difficulty, to the higheſt; and, by ſuch Removals, kept perfectly clean and ſweet as long as deſired.

Whatever Method is taken to preſerve Corn, the Place where it is kept ought to be free from Damps and all Moiſture, as well as from ill Smells of all Sorts; all which ſoon give a Tincture to the Grain, and make it muſty, ill-ſcented, or ill-taſted.

Few who have made any Obſervations in Life, but know how ſoon good or ill Smells are communicated from one Body to another, when placed near together, of which we ſhall ſpeak more at large when we treat of Steeping and Brining. That Coffee gives a Tincture to Tea, when near it, is very well known, and what we are ſenſible of. And the Faculties of many of theſe diminutive Creatures, are much finer than ours, and therefore ſeveral Herbs and Compoſitions may keep them from touching Corn: ſome Things being immediate Death to ſome of them, which we ſcarce perceive. Good dry Wheat ought to be placed in a clean ſweet Place for keeping, and it will not be right dry for the Purpoſe till after March, according to the Opinion of the beſt Judges.

The Reader will obſerve, that the Subſtance of all the Methods for preſerving of Corn is much the ſame, to wit, To have what is good, ſweet and dry at firſt; and to keep it from Air, Wet, and Vermin after.

As to Vermin, the waſhing the Walls and Floors with bitter Herbs and Drugs, with Leaves of Wormwood, Vinegar, Beaſts Galls, &c. is very ſerviceable, and where there are uſed Weaſles or Worms will ſeldom bite; and the Aſhes of green Oak are ſaid to be the killing of Mites when ſpread on the Floor.

We before mentioned the Power of Lime ſlaked in this Reſpect; and Brimſtone ſeems to have an Effect beyond every Thing of this Kind. It is well known that when a little of it is taken inwardly, it will communicate a Smell through the Body to the Cloaths the Perſon has on; and, if applied outwardly, will colour Money in the Pocket. Dr. Hale has ſeveral curious Remarks relating to it; which, with ſome other Obſervations, and a few other Things of the ſame Nature will be mentioned under the Head of Steeping and Brining of Seeds and Grain. And therefore we ſhall proceed to the laſt Thing propoſed to be conſidered, under the Article of Wheat, which is,

A Calculation of what Seed Wheat is required when ſowed at different Diſtances; and of what Produce may be reaſonably expected from each different reſpective Method.

An Acre of Ground contains four Thouſand eight Hundred and odd ſquare Yards; and in the

the following Calculations, I ſhall compute it by even Numbers; that is, by five Thouſand Yards to be ſowed; and making Allowances for Thoroughs, Headlands, and other Accidents, ſhall reckon four Thouſand Yards to produce Corn, we ſpeak here only of the common old Methods of Huſbandry.

Now an Ounce of Wheat may be computed by an even Number, to contain ſix Hundred Grains; and there being ſixteen Ounces in a Pound, there will be nine Thouſand ſix Hundred Grains in a Pound: and there being about ſixteen Pounds commonly in a Peck of Wheat, there will be one Hundred fifty-three Thouſand ſix Hundred Grains in a Peck of Wheat, reckoning a Buſhel of Wheat at ſixty-four Pounds.

An Acre of Wheat ſet at twelve Inches Diſtance, allowing Seed for five Thouſand Yards, for the Reaſon before mentioned, will take forty five Thouſand Grains, not quite five Pounds, or the twelfth Part of a Buſhel.

But when the Grain is ſet at eight Inches Diſtance, it requires double the Number of Seed: that is, eighteen a Yard, being ninety Thouſand Grains, not near a Peck of Wheat.

When the Corn is ſet at ſix Inches Diſtance, there will be thirty-ſix Grains in a Yard, and one Hundred and eighty Thouſand Grains in an Acre, as computed above.

And when the Grain is ſet at four Inches Diſtance, there will be eighty-one in a Yard; and, in the whole Acre, four Hundred and five Thouſand, not three Pecks of Wheat. And reckoning one Hundred fifty-three Thouſand Grains to a Peck of Wheat; and ten Pecks of Wheat, which is the common Allowance of Seed to an Acre, as we uſually ſow the Ground, there will be one Million five Hundred thirty-ſix Thouſand Grains of Corn to an Acre; and ſo there will be near four Grains ſowed on every ſquare of four Inches; that is, almoſt a Grain to every two Inches ſquare, or four cubic Inches.

The uſual Product of Wheat when reckoned pretty good, is commonly about five Quarters, which is ſixteen Times the Seed that is generally ſowed, which is a better Produce than they had formerly in many Places. We are informed by Cicero and Pliny, that ten for one was the higheſt Produce of an Acre, but the ordinary Produce was eight, with which the Huſbandman was well content.

The Ears of Wheat uſually contain from about thirty to above forty Grains each, and taking forty as the middle Produce (which will be high enough) and allowing twelve Stems to each Grain of the Corn ſet at a Foot Diſtance, which is as much as they will bear without the Benefit of Horſehoeing: and reckoning four Thouſand Yards (as above ſtated) to produce Corn, then each Stem producing four Hundred and eighty Grains, there will be in the whole thirty ſix Thouſand Times four Hundred and eighty; which in the whole will be ſeventeen Millions two Hundred and eighty Thouſand. And there being ſix Hundred fourteen Thouſand four Hundred Grains in a Buſhel, there will not be forty Buſhels in an Acre ſo ſet at a Foot Diſtance, with the ſuppoſed Produce of twelve Stems to each Grain, and forty Grains to each Ear.

When the Grain is ſet at eight Inches Diſtance, there will be double the Quantity ſowed; that is, eighteen Grains in each Yard, and eight Stems to each Grain of Seed, the Number of Seeds will be ſeventy-two Thouſand; which, being multiplied by three Hundred and twenty Grains ariſing from eight Stems, the Produce will be twenty-two Millions and forty Thouſand, which is about a fourth Part more than what was ſuppoſed to be produced from the Seed ſown at a Foot Diſtance, this being ſomewhat above ſix Quarters to an Acre.

When the Grain is ſowed at ſix Inches Diſtance, with an Allowance of ſix Stems to grow from each Grain, there will be one Hundred and eighty Thouſand Grains of Seed; that is, thirty-ſix Times five Thouſand.

And it being preſumed there will be four Thouſand Yards that will bring Corn, and that each Yard has thirty-ſix Grains of Seed ſowed on it, and that each Stem has forty Grains; that is, two Hundred and forty Times thirty-ſix, multiplied by four Thouſand, makes thirty-four Millions five Hundred and ſixty Grains of Corn, which is a third more than aroſe from ſowing at eight Inches Diſtance; and, conſequently, above nine Quarters to an Acre.

When the Grain is ſet at four Inches Diſtance, and four Stems allowed to ariſe from each Grain for four Thouſand Yards; there will be eighty-one Times four Thouſand Seeds to be reckoned to produce Corn; and then there will be in the whole three Hundred and twenty-four Thouſand Seeds, which being multiplied by one Hundred and ſixty Times, each ariſing from one Corn with four Stems, and each Stem ſuppoſed to bear forty Corns, the whole will make fifty-five Millions eighty-four Thouſand, which will be near a third Part more than thoſe ſet at ſix Inches Diſtance are ſuppoſed to produce; and three Times as much as thoſe produce which were ſet at a Foot Diſtance, and would be near twelve Quarters, which have been frequently obtained in the common Way of ſowing.

If we ſhould go into the Conſideration of Grain when ſowed cloſer together than four Inches, we ſhall come into that Uncertainty of the Diſtance which falls to the Share of each Grain in the uſual Methods of ſowing. All theſe Calculations ſuppoſe the common Method of Huſbandry to be uſed; we have ſhewn before the Quantity procured by Corn ſet at a Diſtance and horſehoed.

The Reader will not think that theſe Calculations are to be depended on as exactly true, ſince they are only made in order to give him a general View of what may reaſonably be expected from ſetting Corn at ſeveral Diſtances; and, perhaps, may be found in general as near the Truth as can be expected in an Affair of this uncertain Nature; in which the Writings and Practice of others have been of little Service to direct me; but which I have endeavoured to collect from ſome Rules in Huſbandry pretty well eſtabliſhed, and from ſome Rules of Proportion;

portion; which, in many Caſes, ſerve as very good Guides to argue from; and which, I hope, will be of ſome Service to the Reader.

And if theſe Calculations be tolerably well founded, then the ſowing Wheat in Stitches by hand, as before mentioned, at four, five, or ſix Inches Diſtance in the Rows, and in the ſame Proportion in other Caſes, may perhaps conſidering the unavoidable Loſs of many Seeds, and Vacancies of many Places in all Fields, be as good a Rule to go by, as any can be given in general: for, whatever may be ſaid of the great Extent of ſome Roots of Wheat in Depth and Breadth, four or five Inches either way will be a good Allowance: unleſs we take into our Conſideration the Obſervations of Dr. Hale, of the great Depths ſome Plants receive Nouriſhment from, which they certainly may have the Benefit of conveyed to, or obtained for them, by the Heat of the Sun and Air above, or Warmth of the Earth below; which we ſhall have Occaſion to conſider more at large hereafter.

There is one Advantage that may ariſe from tranſplanting of Wheat, which may not improperly be added to what was before ſaid on that Head; which is, That by this Means the Farmer may have an Opportunity of giving his Land to which the Corn is to be brought, the Advantage of more Plowing, and lying to ſweeten; and alſo the Benefit of the Winter Froſts and Snows, which all good Farmers know to be exceedingly advantageous to their Land: and what the ingenious Dr. Beal ſays on this Subject, cannot but make a deep Impreſſion as to the Benefit which may accrue by this.

"I do often, ſays the Doctor, aſk Gardeners "and ſkilful Huſbandmen whether all Sorts of "Land are more fertilized, or more ſpeedily by "the ſolar Influence in our Climate, or by "Froſt; and they generally anſwer, That Froſt "and Snow make the quickeſt Diſpatch a-"mongſt us, and the more general and richer "for Fertility *. And ſuch a tranſplanting of Wheat, may, in all Probability, be often a great Advantage to the Wheat itſelf; for whenever that is too rank, it muſt be eaten or mowed down, or will be ſpoiled. But ſuch a Removal of it will give a proper Check to its Growth, without any Prejudice to the Wheat. And the taking up of young Trees when they are too vigorous, and ſetting them down again immediately in the ſame Place, is practiſed by Gardeners, and adviſed by ſome very good Writers for the very ſame Reaſon, that the removing the Wheat when too rank is propoſed, That is to give an eaſy Check to its too forward Growth.

* *Philoſ. Tranſact.* vol. II. p. 731.

Of brining or ſteeping Corn or other Seeds.

We ſhall firſt mention the Advantages propoſed by this Practice; and then conſider the ſeveral Ways of ordering it beſt.

From the brining or ſteeping of Seed Wheat, or other Seeds, the following Advantages are propoſed to be obtained:

Firſt, That it will certainly make the Seed to grow, and come up pretty much together; and, conſequently, have the faireſt Proſpect of being ripe together.

Now theſe often happen otherwiſe when the Seed is not ſteeped, as part of it may fall where it may be brought to ſprout ſoon, and part lie long in the Ground before it does ſprout; and in caſe a long dry Seaſon follows ſuch ſowing, ſome Seeds, as Barley, and ſeveral others, may not come up at all, or in ſuch a Manner as quite to ſpoil the Crop.

The ſecond Advantage propoſed by this Method, or ordering the Seed, is the ſecuring it againſt Birds, and Vermin devouring it, and its being ſpoiled by Smut. And,

Laſtly, That the Seeds ſteeped in proper Ingredients imbibe a fertilizing Richneſs from the prepared Liquor; or by the Lime uſually caſt on it, and adhering to it, at the Time of the ſowing it.

Now, That both Salt and Lime, which are the Ingredients moſt commonly uſed on this Occaſion, when properly applied, are very great Fertilizers of Land for the producing of Corn, is too plain to need any Proof: the known Uſe and Advantage reaped by them, puts this beyond all doubt; and that they are equally deſtructive of Vermin, is alſo found by the conſtant Experience of all concerned with Salt and Lime.

And all Houſewifes know how effectually Salt preſerves all Manner of Proviſion from the taint by Vermin; and it was before truly obſerved, that the very Smoke of a Lime-kiln effectually clears all who engage in it, from all Manner of Vermin they were before afflicted with; and I have ſeen Caterpillars drop from Gooſeberry Trees, under which a little Lime was ſlaked for a Trial.

The only Queſtion therefore ſeems to be, Whether ſuch imbibing of the Brine, or other Liquor, the Seed is ſteeped in; or the Lime ſo adhering to the Seed, ſhall be a ſufficient future Security of it againſt Vermin and Smut, and be a Fertilizer of it in its Growth.

Now we have undoubted Proofs of the long continued Effects both in Smells and Taſtes ariſing from a very ſhort Application of one Body to another; which we may reaſonably preſume to be the Caſe of Brines, Soots, Copperas, and particularly of Brimſtone, and other Ingredients of the ſame Nature; and the general Uſe of one or other of theſe by moſt Farmers, ſeems to confirm the Advantages reaped by them.

Good and bad Crops are undoubtedly got both with ſteeping and without, the Advice ſome give to keep the Ground clean and ſweet, to till it well, is certainly very good, and ought to be purſued by every ſenſible Farmer, whether he ſteeps his Seed or omits it.

Many are ſtrenuous againſt ſowing the uſual Quantity of Seed, and favour the Drill Huſbandry; but if little Seed be ſown, and nothing done to ſecure that little againſt voracious Birds, and deſtructive Vermin, I doubt they would ſoon make ſuch Devaſtation, as would leave many Vacancies free from any Corn at all.

There is an Objection I have heard made againſt ſteeping, which is, That when Corn is brined

brined and ſowed in a dry Seaſon, the brined Seed frequently grows mouldy and decays when not covered. But the Steeping, if done right, will ſet it on ſprouting, and it will then ſtruggle hard to live: and it certainly is in as great Danger of being devoured when not ſteeped, by lying open, as of growing mouldy by being brined. But the uſual Quantity of Corn ſowed will abundantly ſupply ſuch little Accidents: and this very Objection ſeems to ſhew, that the Steeping preſerves it from Vermin, when it is ſuffered to lie uncovered without being carried off by Birds, or devoured by Inſects.

No one ſeems to deny, that a regular Steeping will certainly produce the ſprouting of the Seed, and all the Conſequences of it, which is the firſt Advantage propoſed by it.

This Advantage cannot be hoped for, unleſs it be ſteeped in a proper Manner; for throwing a little Urine or Salt Water over the Seed is ſo far from obtaining this firſt End propoſed, that it will rather produce the direct contrary Effect, by occaſioning thoſe Grains which happen to be brined, to vegetate ſooner than the others which are not brined.

Whereas it muſt be a regular Brining of the whole that can produce a regular Vegetation of all, which is the firſt Advantage propoſed. And it is undoubtedly on this Account, that in all ſenſible Receipts for Brining, an induſtrious and repeated ſtirring of the Seeds in the ſteeping Liquor, is ſo earneſtly and ſo conſtantly preſſed.

And here I cannot but obſerve, that the firſt Waſhing, or repeating Waſhings of the Seed in fair Water, directed in ſome of the Receipts, ſeems to me prejudicial to the End propoſed by ſteeping it. For as the Seed can imbibe but a certain Quantity of Liquid, if it ſuck firſt a Quantity of fair Water, it cannot after retain ſo great a Quantity of the ſteeping Liquor it would otherwiſe do; and probably this might make it neceſſary for Colonel Plummer and others to make their Brines ſo extravagantly ſtrong, when as good an Effect would have been found by a much weaker Brine, applied in the firſt Inſtance, or from whatever other Liquor the Grain was to be ſteeped in.

And as to the clearing of Seeds, light Corn, and ſuch Trumpery: as Salt Water is ſpecifically heavier than freſh Water, that Refuſe would riſe better on the Brine when the Seed was well ſtirred than in fair Water; and, conſequently, be the eaſier and more effectually ſkimmed off.

And here it may not be amiſs to take Notice of a Remark or Objection made by a very ingenious living Writer, to Seeds, in regard to the Danger many of them will run of burſting, if ſowed in a wet Time, or if a wet Seaſon ſoon follow; which Danger or Difficulty, or whatever you pleaſe to call it, may, I think, when neceſſary, be eaſily and ſafely guarded againſt, by enuring them gradually to gentle Degrees of Moiſture, according to their Nature; and then committing them, and the Soil they were moiſtened in, to the open Earth, which I have tried ſucceſsfully in ſeveral Inſtances. And if we once knew what Degree of Moiſture any Grain or Seed will bear at firſt, without receiving of Prejudice, it can be no great Difficulty to uſe them in the Manner they are able to bear at firſt; and then commit them to the open Air, when they muſt be ſometimes hazarded in, whatever Method is taken in the Management of them. And, I preſume, all thoſe Seeds muſt be forwarded by ſome ſtrong working Preparative, before they are committed to the Ground, when the Gardeners can raiſe a Sallad during the Roaſting of a Joint of Meat, or in a very few Hours.

But to return to Brining.

It ſeems very plain from conſtant Experience, from the Reaſon of the Thing, and the Nature of ſeveral Receipts for Brining and Steeping before-mentioned, that many Sorts of Seeds may be made certainly to grow, and that equally as to their Time of ſprouting by Brining or Steeping, which was the firſt Advantage propoſed to be obtained by Brining or Steeping of Seeds and Grains. And the next Thing to be conſidered is, the

Second Advantage propoſed by Brining or Steeping Seed or Grain, which is, The ſecuring it againſt Birds or Vermin devouring it, or its being ſpoiled by what is called Smut.

The ſteeping of Seeds was well known in Virgil's Time, and that with Ingredients, in order to ſecure it againſt deſtructive Vermin long ſince. For Sir Hugh Plat in his Garden of Eden*, mentions Lime beaten to Powder, and mixed with Corn before it be ſowed, to prevent Rooks and other Fowls from devouring it, and puts a Queſtion, if it does not alſo help to enrich. And in another Place he mentions, the laying Peaſe in Water a Day or two before they are ſown, and puts a Queſt. of ſteeping in Milk, Spirit of Wine, or Water that hath been long infuſed on Dung, waſte Soap Aſhes, or common Aſhes, whoſe Heart and Salt hath not been drawn out before. And mentions ſome Experiments to procure the Growth of Seeds in a few Hours.†

* Page 61, 62.

† Part II. p. 10.

What is above-mentioned as then thought practicable, has for ſome Years been found, by repeated Experience, to be right: and moſt Farmers now uſe one Sort of Brine or Steeping Compoſition or other for ſeveral Sorts of Grain: and, we may preſume, that ſo general a Practice, and the Advantages procured by it, when properly managed, will ſufficiently juſtify the Proceeding in the ſame Courſe of Huſbandry; for I do not find it objected to, that Vermin, notwithſtanding the Steeping, ſtill devour the Corn, which happened to a Field of the ſenſible Farmer before ſpoke of; who told me, That the Blades of his Wheat (unſteeped) turning yellow, and dying away; on examining into the Ground, he found all the Grain gone.

But as the Methods of Steepings and Brinings are exceeding numerous, and very various, it is next to an Impoſſibility to chuſe out ſuch as will fit all the different Sorts of Grains and Soils; but they all do, or ſhould point at the ſame End. To wit, To convey ſomething to the Grain or Seed diſagreeable or deſtructive to Vermin and Birds; and which at the ſame Time may fertilize or enrich them. We will conſider

the

the former as it falls under this preſent ſecond Head. And the latter, when we come to the following third Head: and then conclude with ſome ſuch Obſervations which may ariſe from the Whole.

In order to do that Juſtice to ſteeping which it deſerves, we ſhall conſider,

Firſt, The Reaſonableneſs of ſuch a Procedure; or the Grounds we have to believe that Steeping or Brining will ſecure the Grain when ſowed.

Then thoſe Conſequences which repeated Experience hath taught us generally to ariſe from ſuch Steepings and Brinings.

Now it is not to be doubted but that moſt Creatures have a Senſe of what is agreeable or diſagreeable to them, and avoid the latter as far as is in their Power, as is plain when Soot is laid round Vegetables; which, whilſt freſh, keeps off Vermin from them.

Again, it is equally evident that ſeveral Compoſitions, or ſingle Things, are fatal to one or more Species of Creatures, which affect not others at all; or ſo little as not to give them any conſiderable Uneaſineſs.

Thus Lime when ſlaked, Salt, Smoak, and Brimſtone, are Death to many ſmall Inſects.

Thus the Oil of Turpentine, or Smoak of Tobacco, will kill Moths; and, at the ſame Time very little affect us, or many other Creatures. And the rubbing of Hangings and Furniture with Sheeps Wool before it has loſt its natural Fatneſs, will ſtop the Progreſs of Moths; but do not occaſion any Manner of Uneaſineſs to thoſe who live or lodge in them, any farther than the Smell of the Wool may be diſagreeable to ſome.

But as the Sheep's Wool has this Effect in this Caſe, may it not be reaſonably concluded, that it will operate much ſtronger againſt Vermin when the Sheep lies on them in the Fold. It is commonly known that the folding of Sheep helps to deſtroy Slugs and Worms in the Land, and there is the ſame Reaſon to expect the Effect in one Caſe as in the other. And this well deſerves the Obſervation of the Curious, it never having been taken Notice of that I know of.

Again, the Faculties of theſe diminutive Creatures are certainly much finer than ours, both as to their Smelling, and their being affected by Scents; of which ſeveral Inſtances might be given of little Creatures. But the curious Smell which Dogs have, and which all Sportſmen, and moſt other Perſons are well acquainted with, would appear very ſurprizing were it not ſo commonly known.

Fumes of Brimſtone will make Leaves wither, though at ſo great a Diſtance from them, as to occaſion it by the Heat of it; and to Animals are moſt deadly.

'Tis thus the Fumes of this Brimſtone may be uſed as an excellent Remedy to deſtroy Vermin; and it preſerves Corn and Bread when packed up to go Abroad.

The ingenious Dr. HALE ſays, he is told that it is by ſome ſuch Methods as theſe, that all the Rats in Ships are deſtroyed when in the Harbour. And he farther obſerves, That the Fumes of burning Brimſtone, placed under Corn, will aſcend through it with great Velocity and Acrimony.

But if it be placed over it, it deſcends not, for Ants in a Muſlin Rag at the Bottom of ſuch fumed Corn, were not killed by it. Which Obſervation ſhews that learned Gentleman's Thoughts of Brimſtone in deſtroying little Animals; and, indeed, the ſurprizing Effects of Brimſtone are ſcarce credible by thoſe who are unacquainted with it; and we have Reaſon to think much greater Effects will be diſcovered from it hereafter. But whoever engage in Experiments about it, had need to uſe great Care in what they do, there having been ſo many fatal Accidents occaſioned by it.

I ſhall only add on this Head, the ſurprizeing Effects of the Liquor uſed by the Bug-killer at the Houſe of a Friend of mine. The Houſe was long terribly peſter'd with Bugs, and the Bug-killer took down all the Beds and Furniture, and waſhed them and the Bed-poſts, &c, and the Walls of the Rooms with his Liquor, and then replaced them, and it is now above three Years ſince; and from that Time there has not been a Bug ſeen in the Houſe. Nor was the Operation attended with any ill Smell, or other ſenſible Inconvenience to any of the Inhabitants, the Dogs or Cats. Nor did the Ingredients ſtain any Thing, or prejudice the Frames of Pictures.

We cannot but obſerve that here was a viſible immediate deſtroying of the Bugs; and a laſting preventing of their return again for ſeveral Years already paſt; and, in all Probability, (as the Man promiſed) for many more yet to come.

This Effect muſt certainly be owing to the Power of the Liquid then uſed, ſtill remaining, and keeping off the Bugs either by its Smell, Taſte, or other deſtroying Power which the Bugs perceive; but are no Way felt by any other living Creature in the Houſe, as far as we know.

And why may not ſomething of the ſame Nature be contrived to be proper, ſafe, and effectual Securities for the ſeveral Grains and Seeds both in the Fields and the Gardens, till they are tolerably well armed againſt theſe great little Enemies, and their greater ones too.

I know ſeveral Farmers who put Arſenick into their Brine for Wheat, and apprehend it very beneficial; but this is a deteſtable Practice: and what is more ſurprizing, we are aſſured, that the Caſſada Plant unprepared, poiſoneth; but, prepared, is the very Bread of the WEST INDIES.

What is offered above, may, in a great Meaſure, convince us what Conſequences may ariſe from proper Steeping and Brining, which frequently are the preſerving the Grain and Seed from being devoured, when ſowed, by either deſtroying the pernicious Vermin themſelves, or giving the Seeds ſuch a Tincture or Cruſt, as will prevent their eating them: as it is well known the Caſe is when Soot, Lime, or other bitter Things are applied to, or about the Grain

or

or Seed, which conſtantly remain untouched, whilſt the Soot, and ſo on, conſerve their bitter Quality.

And indeed all the Things commonly uſed alone, or in Compoſitions for brining or ſteeping Grain and Seeds; ſuch as Salt, Lime, Soot, Copperas, Nitre, Flour of Brimſtone, Dunghill Water, Bay Salt, Urine, &c. are generally ſuppoſed to have a Power to deſtroy thoſe Species of Animals ſo pernicious to Seeds, or at leaſt to preſerve the Grain from being devoured by them; or elſe to be endued with ſuch a fertiliſing Quality, as to forward the Sprouting and Growth of the Grain and Seed: and moſt of them certainly have one or other, or all the laſt-named Qualities. And their Uſe in preventing Smut depends on the ſame Reaſoning and Experience, as muſt appear to the Reader from what is before mentioned, and which will be further confirmed by what we ſhall offer hereafter, ſo we ſhall here come to the third Head, which is,

That the Seeds ſteeped in proper Ingredients imbibe a fertiliſing Richneſs from the prepared Liquor, or from the Lime uſually caſt on it, and adhering to it at the Time of ſowing it.

Now the Truth of this will, in a great Meaſure, appear from the general Courſe of Huſbandry, in applying Manures in order to promote the Vegetation of Grain, Seeds, and Plants; by which ſome particular Advantages are propoſed to be obtained by the Conſent of all Farmers. And therefore it may be taken for an indiſputeable Truth, being founded on Reaſon, and confirmed by conſtant Experience, That the Growth of Seeds is to be forwarded by the Application of proper Manures to them.

And on a little Examination it will be found equally true, that ſome Sorts of Manures promote the Vegetation or Growth of ſome Grain, Seeds, and Plants, much ſooner than others do.

This, I preſume, will ſcarce be diſputed by any Farmer, or indeed any Perſon the leaſt converſant in Affairs of this Nature; however, I will give an Inſtance or two to put the Matter out of doubt. Pigeon's Dung is undoubtedly richer than Cow Dung; and a Load of any feeding on Animals will encreaſe Vegetables much more than a Load of Dung of Cattle fed on Straw. This is ſo plain that there can be no Occaſion to add any thing further about it.

Theſe Truths therefore being eſtabliſhed, it only remains to ſhew, that the ſteeping ſo ſhort a Time as is uſually practiſed in ſteeping of Grain and Seeds, may convey a laſting Benefit to the Growth of the Seed ſo ſteeped.

And that it may do ſo is no novel Notion, but has been the Opinion of very conſiderable Writers.

In the Work of Fructification I think (ſays Sir H. Plat) that Corn itſelf may be ſo philoſophically prepared, only by Imbibition in the Philoſopher's Aquavitæ, that any barren Ground, ſo as it be in Nature kindly for Corn, ſhall bring forth a rich Crop, without any Matter added to the Ground *. And Digby mentions a Plant of Barley all riſing from one Corn, that by ſteeping and watering with Salt Petre diſſolved in Water, brought forth two hundred and forty-nine Stalks, and above eighteen thouſand Grains. And another Gentleman had from three Spires of ſteeped Barley ſixty, ſixty-five, and ſixty-ſeven Stalks apiece from their ſingle Grain and Root, with every one an Ear on, and about forty or ſomewhat more Corns apiece in them †.

* Sera n Eden, 37.

† *Philoſ Tranſact.* vol. IV. 2d part, p. 310, &c.

Many other Inſtances of much later Date, to much the ſame Purport, might be added; but the Gardiners raiſing Sallads in a few Hours, and ſeveral Greens in a few Days, of which we have had many indiſputable Proofs, ſeem to prove the Point in Debate beyond all Poſſibility of Contradiction.

For this ſudden Growth of the Plant muſt either be owing to the ſimle unfolding of the inſant Seed into a vegetable Plant, or to the Operation of the Compoſition uſed for the Increaſe of it, and if it would grow ſo without the Help of the Compoſition, it would conſtantly do ſo; and therefore we cannot but conclude, that proper Compoſitions applied to Vegetables but for a ſmall Time, may, and do oft convey a very fertiliſing Power toward the Growth of Grains and Plants, and to Trees too.

This Argument ſeems concluſive, That a ſhort ſteeping may convey ſuch a laſting fructifying or fertiliſing Quality, as will be of a continued Service to the Growth of the Plant.

And we find ſeveral Things much more incomprehenſible of laſting Impreſſions made in a very ſhort Time.

We are all ſenſible how ſoon the Touch of a Loadſtone conveys a laſting Impreſſion to the Needle.

We all equally know that a little Bud from a ſtriped Holly, put into a large green Holly, will gradually occaſion the whole green one to become ſtriped, though the Bud dye away.

Many other Inſtances might be offered, particularly of the wonderful Effects of Poiſons, both as to their working at diſtant Periods of Time, from that they were given; and ſome times directly.

And we farther find it appear, from ſeveral Experiments, and it has been evidently proved by Dr. Keil, that the Growth of a Tree (to which we may add, and of Corn and Plants) very little leſſens the Weight of the Earth in which it grew. Mr. Boyle had Ground dug up, and Plants only watered with Spring Water; one weighed three Pound, and one fourteen, and the Earth was ſcarce diminiſhed: and Helmont dried two Hundred Pound of Earth, and planted a Willow in it of five Pound Weight, which he watered with Rain, or diſtilled Water, and covered with a tin Cover; and in five Years the Tree, and all the Leaves it had borne, weighed one Hundred ſixty-nine Pounds three Ounces, and the Earth was diminiſhed but about two Ounces.

I tried the ſame Experiment in order to ſee how much Turnips took of the Ground, but though ſowed in a freſh Soil, and ſet in an open London Garden, they came to no Subſtance worth Notice.

But may we not from theſe, and other Experiments of the great fertiliſing Qualities of the Air and Dews, reaſonably ſuppoſe that the ſteeping Compoſitions help to expand the unfolding

by different Perſons; to omit the different Management of the Seed after it is taken out of the Liquid.

I conceive, they are very much miſtaken, who imagine the liming it to be only to make it ſow better, which ſeveral other Things eaſier to be had would do full as well; but I apprehend both the Lime and the Salt adhere to the Seed, and not only guard it by their Taſte and Sharpneſs, as long as their Virtues remain, but alſo communicate ſome of theſe their Properties to the growing Plant, and alſo occaſion ſuch a Ferment in the Earth as helps the Plant to proper Juices for its Nouriſhment.

Lime may very well acquire Heat enough from a Lime-Kiln, to operate a few Days; and the well known Qualities both of Lime and Salt, are to deſtroy Vermin, and promote the Growth of Wheat.

So that as far as we can rely on our Reaſoning in theſe Caſes, or truſt to our Experience, Lime and Salt may be ſafely and plentifully uſed in ſteeping and brining of Wheat.

It is very probable that by a few careful Experiments, made at different Times, and in different Ways, this Manner of brining, &c. may be brought to a reaſonable and very uſeful Certainty, as to the general Practice. And perhaps the Wheat itſelf may be found, when rightly ordered, to imbibe ſuch Quantities only of each Ingredient, as will beſt anſwer the Ends deſired; and at the ſame Time refuſe ſuch Overplus, or ſuch Kinds of Juices as may be found prejudicial to it.

It will certainly be proper to avoid uſing Ingredients alone which are too ſtrong for Wheat, ſuch as Urine, when not qualified with ſome other Ingredient; and not to keep the Seed ſo long in any Compoſition, as may rob or deprive it of its vegetative Quality. This may be eaſily guarded againſt, by trying any Compoſition the Reader is inclined to uſe, or to form from the ſeveral Compoſitions and Ingredients herein before-mentioned in ſmall Quantities, which he may eaſily make ſtronger or weak; and ſteep the Grain in them longer or ſhorter, and ſow it for Trials, all which may be done with a little Care, at a trifling Expence, and then he may adhere to what he finds beſt to anſwer his Purpoſe.

I am not ſenſible that I have named any one Receipt or Ingredient as uſed in the brining or ſteeping of Wheat, but what may be ſafely uſed, without pointing out one way or other the Danger or Inconvenience which may ariſe from it.

And though moſt of them are very much applauded, yet I have taken the Liberty to touch on ſome Things, which I apprehend may be altered in them, or where they may probably be applied in a more efficacious Manner.

I have alſo named ſome Steepings I have tried, and what may be relied on from them; and as I have ſeveral others now depending, I ſhall be glad to meet with ſuch Succeſs, as to make the publiſhing of them, toward the Concluſion of this Undertaking, of ſome Uſe to the Publick. And if other curious Perſons would communicate theirs carefully made, it may be preſumed that our united Endeavours will produce what may be of real and laſting Advantage to the Farmer, the Gentleman, our Country, and indeed to all Mankind.

Lime and Salt are undoubtedly excellent Ingredients, and ſo are ſeveral other Things mentioned in ſome of the Receipts for brining abovementioned; and if Brimſtone can be brought to be uſeful in theſe Affairs, either alone or with other Ingredients, both the Smell, the piercing Quality, and great Power in the deſtroying of Vermin, ſeem to promiſe as fair for its being very ſerviceable for the preſerving of the Seeds of Grain and Vegetables, as any one thing whatſoever.

Of BARLEY.

Barley is generally eſteemed the next uſeful Grain to Wheat amongſt us, and conſequently it ought to engage our ſecond Care; how deſervedly it is ſo, we ſhall leave the Reader to judge, when we have conſidered them ſeverally and reſpectively.

On the Succeſs of the Wheat and Barley in the Corn Countries, our Farmers generally depend for the Payment of the principal Part of their Rents, and for the Happineſs of themſelves and Families; the other Grains being expected rather to provide Conveniencies for themſelves, and to maintain their Stock, than to raiſe any great Sums for them; and theſe two Wheat and Barley, are accordingly cultivated with great Care, and commonly at a very great Expence.

Barley hath a thick Spike; the Cup, Huſk, Awn, and Flower, are like thoſe of Wheat or Rye; but the Awns are rough, and the Seed ſwells in the Middle, and for the moſt Part ends in a ſharp Point, to which the Huſks are cloſely united.

The great Uſe of Barley is to make Beer, which, as well as the Method of making it, is very well known.

In ſome Counties they make Bread of it, but it is ſo coarſe and unpleaſant, that few like to eat it, who have ever taſted Bread made of Wheat; nor will many uſe it for this Purpoſe, whilſt Wheat continues ſo cheap in Proportion to Barley, as it has done for ſeveral Years paſt. Wheat Bread, when all Things are conſidered, being now the cheaper of the two.

It is alſo uſeful in the Grain, and when ground into Flour, to be given to the ſeveral Sorts of Cattle, and for the feeding of Fowl.

But it is far more beneficial moſt ways, when made into Malt; for it is then ſo ſweet, and endued with ſo fattening a Quality, that few Things exceed that Way: and the excellent Maſhes then made of it for Horſes, and other Cattle, are very well known. This ſhews the fine Spirit which is originally in this Grain, ſince neither the ſteeping, or the drying it for Malt, can take ſuch a Spirit to it.

The great Uſe made of it by the Diſtillers, abundantly ſhews the Spirit that is in it; though I cannot think with a Reverend Writer, that the Revenue it occaſions is to be reckoned amongſt the good Qualities of the Grain; but muſt rather think our National Taxes a Puniſhment for our National Sins.

There is ſome Difference amongſt our Writers, as to the Names and Sorts of our Barley; RAY mentions three Kinds.

1. Hordeum diſtichum; common Barley.

2. Hordeum diſtichum minus; Sprat Barley, or Battle-door Barley.

3. Hordeum polyſtichon; Winter, or ſquare Barley, or Bear Barley, called in the North, where it is commonly ſowed big.

And he adds, he could not forbear to mention, that LOBELIUS wrote, That the BRITISH Malt Liquors far exceeded all other Northern Liquors of that Kind; of which he was a proper Judge, being a FRENCHMAN, and having travelled in thoſe Countries where Malt Liquors are uſually drank.

The Rev. Mr. LAWRENCE mentions four remarkable Sorts of Barley.

Firſt, The long-ear'd Barley, moſt generally eſteemed, for all Uſes and all Sorts of Land.

Second, The Sprat, or FULHAM Barley, which is beſt for rank Land, becauſe it runs not ſo much into Straw as the common Sort does, and it is thought to yield better.

Third, The Hotſpur, or RATHRIPE Barley, which is the earlieſt ripe of any, being commonly got in, in nine or ten Weeks. Now this is conſequently very uſeful on many Accounts, for that Reaſon, as it may be ſowed later, and will ripen in thoſe Places where the others ſcarce will grow; and it gives the Farmer the Command of ſome Weeks, either before the ſowing it, or after the reaping, which is often of very great Advantage in the Courſe of Huſbandry, eſpecially ſince the Improvements made by Turnips; ſo that he may eat his Turnips longer, or ſow later with this Barley than the other, the Advantages of which will be mentioned, when we come to treat of Turnips. And there are Inſtances where two Crops of this Barley have been got in one Year, from the ſame Land.

Fourth, SCOTCH Barley, which this Author ſays gives the Drink made of it a Taſte generally diſagreeable to Strangers; and it has alſo a purging, raking Quality, of the ſame Nature as Rye, when made into Bread.

MILLER mentions five.

Firſt, The common long-ear'd Barley.

Second, Winter, or Square Barley, or Bear Barley, by ſome called big.

Third, Sprat Barley, or Battle-door Barley, as Mr. RAY.

And theſe, he ſays, are commonly cultivated near LONDON; but unthinkingly, in the very next Page, adds, That the Square Barley, or Big, is chiefly cultivated in the North of ENGLAND, and in SCOTLAND, and is hardier than the other Sorts; but ſeldom ſown in the South of ENGLAND, though it might be cultivated to good Purpoſe, on ſome ſtrong, cold, clayey Land, where the other Kinds do not thrive ſo well. But ſuch Slips as this muſt be expected, and allowed for in ſuch an Undertaking.

The other two Sorts cultivated in ENGLAND, are,

Fourth, The RATHRIPE Barley, before-mentioned. And,

Fifth, The naked Barley, which makes tolerable good Bread, very good Malt, and yields great Increaſe.

Having, under the Head of Wheat, conſidered the curious Fabrick of that Grain, and the Manner of the Growth of it; that may, in a great Meaſure, be applied to the other white Corns: and therefore I ſhall offer no more of that Kind here.

The principal Uſes of Barley, and ſeveral of the peculiar Qualities of the different Sorts of it being before-mentioned, we ſhall not repeat it; but only obſerve in general, that all theſe ſeveral Sorts of Barley are to be ſowed in a dry Seaſon, and at different Times, according to the Nature of the Soils they are to be ſowed in, and the Sort of Barley you ſow them with. And it may, in general, be ſowed from the Beginning of FEBRUARY, but rather in MARCH and APRIL; and the RATHRIPE will bear ſowing in the Beginning of MAY, and do very well, eſpecially if properly ſteeped.

Barley has the ſhalloweſt Roots of all the white Corns, and yet ſtands firm notwithſtanding it has a very tender Footing.

It will not grow in many Soils where Wheat will; a loamy ſtiff Earth is not proper for it, unleſs it be brought into an exceeding fine Tilth, which it requires, and alſo as rich a Soil, and as much Culture as any Grain whatſoever.

And as Barley is mentioned to have the ſhalloweſt Root of any of the white Corns, it may not be amiſs to obſerve, that a late ingenious Author thought there were not many Grains or Graſſes which required above three Inches depth of Soil for their Nurture; whereas both Reaſon and Experience prove the contrary, and as I may not have another ſo convenient an Opportunity of conſidering this Point, I will here mention ſome Particulars on the Subject.

It was mentioned, under the Head of Wheat, that Mr. MILLER had traced the Roots of Wheat a Yard deep, and I have traced them a great Way.

From the Experiments made by the curious Doctor HALE (which Dr. DUMAINBRAY, in his Lecture on OCTOBER the 29th, 1755. aſſured us, when they were publiſhed ſurprized all the learned Bodies in EUROPE, and that they examined them and found them right).

From this ingenious Dr. HALE's Calculations of the violent Heats and Evaporations in the Summer Months, and the ſmall Quantity of Dews which then fall, and the little further Supplies which are given to Trees, Corn, and Vegetables, frequently for a long Time together by Rains, conſidering the great Quantity of Moiſture which is daily drawn from, or perſpired by the Trees, &c. The Trees, Corn and Vegetables would be dried quite away were they not ſupplied with Moiſture from ſome other Origin, which he reckons to come from the Moiſture in the Earth two or three Foot deep under the Trees: which, together with the Rains and Dews, ſupplies all the Plants with Moiſture ſufficient to keep them alive; and, in ſuch a Condition, as is proper for their well being in general.

And ſince theſe Experiments have gained ſuch a Cha-

a Character, I doubt not but the Subſtance of thoſe which relate to this Particular, will be agreeable to the Reader; eſpecially as I ſhall only give the Reſult of his ſeveral Calculations, as I have abridged them; ſince they are certainly very curious, and may be uſeful on many Occaſions, as well as in Huſbandry, and will accordingly hereafter be referred to; and to give you the Doctor's own Words as to this Point. "If theſe Experiments and Obſervations "give us any farther Inſight into the Nature of "Plants, they will then doubtleſs be of ſome "Uſe in Agriculture and Gardening, either by "ſerving to rectify ſome miſtaken Notions, or "by helping further to explain the Reaſons of "many Kinds of Culture, which long repeated Experience has found to be good; and, "perhaps, by leading us to make ſome Ad-
* P. 360. "vances therein.*

"For, the farther Reſearches we make into "this admirable Scene of Things, the more "Beauty and Harmony we ſee in them: and the "ſtronger and clearer Convictions they give us "of the Being, Power, and Wiſdom of the
† *Introd* "divine Architect."†

The Doctor apprehends that the Growth of Vegetables is promoted by the Motion of their Fluids, as in Animals; and therefore thinks it reaſonable, that in them alſo, by the ſame Method of Inquiry, conſiderable Diſcoveries may in Time be made, there being in many Reſpects, a great Analogy between Plants and Animals.

He alſo examined their ſeveral Perſpirations, and found that a Man perſpires in twenty-four Hours, as Dr. KEILL reckons, about thirty-one Ounces; and the Plant, allowing for Evening and Morning, twenty-two Ounces: ſo a Man is to a Flower, as one Hundred and forty-one to one Hundred, in this Particular.

He further found that in one and twenty Days in Summer, there were near ſix and twenty Ounces more Wet evaporated from a circular Area of a Foot in Diameter, than fell in Dews: and therefore juſtly concludes, "That "Plants would then periſh, if they had not "ſome other freſh Supplies, either from Rains, "or from below; finding the Evaporation to be four Times as much as the Dews that fall in the Night: and we know by Experience, that for much longer Time often no Rain falls.

On the whole he reckons about two and twenty Inches of Rain to fall in his Neighbourhood, near HAMPTON COURT, in a Year; which may be reaſonably allowed, conſidering the ſeveral Quantities, which, on the niceſt Calculations, have been computed to fall in ſeveral Places, as computed by Dr. DERHAM,‖ being the Reſult of many Calculations, as follows:

‖ *Philoſ. Tranſact.* vol. IV. part II. page 82.

"The Proportions therefore which I ſhall "now lay down for the yearly Rain of all "Places, whoſe Rain I have had Information "of, are theſe,

"For ZURICH (till further Obſervations are "made) thirty-two Inches and a Half.

"For PISA (till further Obſervations) forty-"three Inches and a Quarter.

"For PARIS nineteen Inches.

"For LISLE four Inches.

"For TOWNLEY in LANCASHIRE, forty-two "Inches and a Half.

"For UPMINSTER, nineteen Inches and a "Quarter; all of ENGLISH Meaſure."

Dr. HALE further mentions, That NIC. CREQUIUS found that twenty-eight Inches Depth evaporated in a whole Year from Water; and the Evaporation of the Earth is found to water as one thirteenth to one fortieth; about one third.

The Evaporation of the Earth in a Year is 9-15. (ſomething above nine Inches) from which 9-15 Inches, there are to be deducted 3-39 Inches (above three Inches and a Quarter) for circulating daily Dews; and then there remain 5-76 Inches (five Inches and three Quarters.) Which 5-76 Inches deducted from the Quantity of Rain which falls in a Year, there remains at leaſt 16-24 Inches Depth (ſixteen Inches and near a Quarter) to repleniſh the Earth with Moiſture for Vegetation, and to ſupply the Springs and Rivers.

Hence we find that two and twenty Inches of Rain in a Year, is ſufficient for all the Purpoſes of Nature, in ſuch level Countries as this about TEDDINGTON near HAMPTON COURT.

But it plainly appears above, that the Evaporation in Summer frequently far exceeds all the Dews and Rains which fall then for a long Time; and, conſequently, the Heat would then deſtroy all Plants, unleſs provided for ſome other Way.

In order therefore to find out what Stores of Moiſture Nature had provided in the Earth, againſt the dry Summer Seaſon. The laſt of JULY 1724, the Doctor dug up three Cubic Feet of Earth, three Foot deep (and mentions the Soil, &c. of the Place.) And when thoſe ſeveral three Cubic Feet were become ſo dry as not to be fit for Vegetation, on weighing them ſeveral Times, he found the firſt Foot (the higheſt) had loſt ſix Pounds ten Ounces of its one Hundred and four Pounds four Ounces, being the Original Weight. That the ſecond had loſt ten Pounds of its original Weight of one Hundred ſix Pounds ſix Ounces and a Half. And that the third had loſt ſix Pounds ten Ounces of its original Weight of one Hundred eleven Pounds and one third. Which together amount to twenty-five Pounds two Ounces; and the Doctor apprehends this a ſufficient Reſervoir for Plants in general, in dry Summers and dry Times: for ſeveral Plants ſtrike deep into the Earth, the Root of the Sun-flower he made the Experiment with, reached fifteen Inches into the Earth; and, conſequently, would draw Moiſture much deeper in dry Times than the Depth its Roots reached.

And it is neceſſary to conſider the Heat of the different Times of the Year, and how far that may affect the Generality of Plants; and what they can bear, before they will be burnt up and deſtroyed.

Now in regard to the Heat Plants can bear, the Doctor obſerves, That they will bear without Prejudice a greater Heat than that when Water is heated to the greateſt Degree, he could bear his Hand in without ſtirring it about; and mentions the following Degrees of Heat at different Times:

"That

" That in JULY the common Noon-tide Heat " in the Sun is about fifty Degrees.

" That the Heat of the Air in the Shade in " JULY, is at a Medium thirty-eight Degrees.

" That the MAY and JUNE Heat is from fe- " venteen to thirty Degrees, the moſt general " Heat for the Generality of Plants in which " they flouriſh moſt, and make their greateſt " Progreſs in Growth.

" The Autumnal and Vernal Heat may be " reckoned from ten to twenty Degrees: the " Winter Heat from the freezing Point to ten " Degrees."

The Doctor farther obſerves:

" That in JULY the Heat muſt have a con- " ſiderable Influence at two Foot deep, by " Night as well as by Day.

" That the Dew in a hot Day cannot be of " Benefit to the Roots, but is imbibed into " the Vegetables.

" And that Nature has covered Roots with a " very fine thick Strainer, that nothing ſhall be " admitted into them, but what can readily be " carried off by Perſpiration; Vegetables have- " ing no other Proviſion for diſcharging their " Recrement."*

*Page 85.

Since a plentiful Perſpiration is found ſo neceſſary for the Health of a Plant or Tree, it is probable that many of their Diſtempers are owing to a Stoppage of this Perſpiration by inclement Air.

The Perſpiration of Men is often ſtopped to a fatal Degree, by Intemperance, violent Heats; and that of Vegetables by inclement Air, unkindly Soil, or want of a genial Moiſture.

By comparing the Root, and the Plant above Ground, we ſee the Neceſſity of cutting off many Branches from a tranſplanted Tree; for half the Root being cut off, (which is the Caſe of moſt young tranſplanted Trees) it is plain it has but half the Nouriſhment, beſides its being put in a looſe Poſition.

This (as well as Experience) ſtrongly evinces the great Neceſſity of well watering new Plantations; which notwithſtanding what MILLER ſays, that nothing being more injurious to them than over watering.†

†Page 14. 17.

How the Ground is to be prepared for Barley; and of ſteeping and ſowing it.

Barley (as before mentioned) requires as fine a Tilth, and the Ground to be in as good Heart as any white Corn whatſoever. And accordingly, before Turnips came to be ſo much cultivated, the Ground was generally prepared by a Fallow, a Manuring, and ſeveral Plowings. And the Vale Men who get not Turnips, uſe much of the ſame Huſbandry, or elſe fold it with Sheep, or get twenty Buſhels of Pigeons Dung, and ſpread it on an Acre; when the Barley is ſowed, and harrow it in with it.

But ſince Turnips have prevailed ſo much, they are found generally to prepare the Ground very well for Barley, and now it is commonly ſowed after them; when it is eaſily brought to a fine Tilth, and when the Ground is in good Heart, there is no great doubt of a good Crop.

The Care to provide good Seed, and to make it perfectly clean, is ſo generally to be done in all Grain, that it need not be here inſiſted on, only juſt mentioned; and the Change of Seed yearly, or once in two or three Years, is alſo found very advantageous: and in the Caſe of Barley, that from ſandy ſhort Loam is found the beſt for ſtiff Land, and that from ſtiff for ſandy.

In very dry light Soils it may be ſowed early in MARCH, or any Time after; but in ſtiff Soils not till APRIL, and ſometimes not till early in MAY. But in ſuch late Sowing, if the Seaſon does not prove favourable, you run great Hazard as to the having a good Crop; and may be aſſured it will be a late one, which is generally attended with ill Conſequences, and very often with fatal ones; eſpecially if the Barley be ſowed late, and not ſteeped, and a dry Time follows. In which Caſe, at beſt, the Seed lies long expoſed to Vermin, often comes up unevenly, and ſometimes not at all.

Of Steeping.

Whatever the Seaſon is, a moderate Steeping of Barley, cannot be attended with any conrable Inconveniencies, and may produce many great Advantages; as are mentioned at large under the Head Steeping. And when you ſteep, you may manage it in the ſame Manner as directed for Wheat; and almoſt any of the Steepings mentioned will make it grow; as fair Water will, as is well known by the putting it into the Ciſtern with Water in order to malt it.

The Vale Men ſteep it in Salt and Water in which an Egg will ſwim, twelve Hours; and ſome in Water in which Lime is diſſolved, or ſift dry Lime over it.

The Rath-ripe Barley, as was before mentioned, is ſoon ripe; and, conſequently, there is little Danger in ſowing it late, ſince it frequently is ripe in nine Weeks, from the ſowing and ſeldom exceeds ten. But as the late Sowing muſt probably carry it on to a drier Time, there will be the more Occaſion to ſteep it.

The common Allowance for Seed Barley is from four to two Buſhels, according to the Time of ſowing, the Sort of Grain, and the Nature of the Soil: and taking three Buſhels in the Medium, the Produce being four Quarters, it will be about eleven for one. Whereas if only one half of the three Buſhels grew, and produced but two Stems, that would be ſixty Buſhels, which is twenty Times the Seed; and I have known ſome large Fields to anſwer this Calculation.

A late voluminous Writer applies here the common Saying of, " The more Furrows the " more Corn, which is very inconſiſtent with the Drill Huſbandry, and ſetting the Seeds at a great Diſtance, which he recommends ſo warmly.

Mr. HAMILTON in SCOTLAND ſet a Handful of Barley at ſix Inches Diſtance; which, in three Weeks, covered the Surface, and produced ſeven Sheaves; but they being ſtolen, he could not be ſure of the Produce.‖

Mr. MILLER thinks four Buſhels too much, it being his Opinion, that we generally ſow too much of all Grain. And if the Seed could be inſured againſt Vermin and Accidents, and be

‖ Agent P. 4.

certain to grow, it would be no great Difficulty to aſcertain the Quantity.

Many others ſeem of the ſame Opinion in this Particular, that we generally ſow too thick; and this ſeems to concern all, or moſt Sorts of Corn. I made ſeveral Calculations under the Head of Wheat, of what Produce may reaſonably be expected from Grain ſowed at different Diſtances in the common Huſbandry; which may, in a great Meaſure be as applicable to Barley as Wheat; and therefore no more need to be ſaid as to that here; only that the Method there mentioned of ſowing the Furrows by Hand, may probably anſwer as well for Barley as any other Method whatſoever.

The Manner of Plowing has been ſpoke to before, as well as Rolling; the latter of which is frequently abſolutely neceſſary; and, when rightly timed, and prudently managed, is always advantageous. It ſhould be done after the firſt Shower of Rain after the Sowing.

Of weeding and reaping of Barley.

No Corn is generally thought to ſuffer ſo much by Weeds as Barley, and therefore a very particular Care ought to be taken to preſerve it from Weeds, or to clean thoſe out which are got into it. The common Way of weeding Barley is very well known, and ſome Weeds will get into it either by Accidents, or by lying long in the Ground, and being freſh raiſed up, as was before mentioned.

This is uſually done in June, and if the Corn be then thin, a little Pigeons Dung, Malt Duſt, or any Thing of the like Nature will be of great Service to it.

But if the Ground be duly managed, according to the Courſe of the new Huſbandry, the Ground will not be filled with Weeds carried thither with improper Dung, which is often the Caſe. And if the Barley follow Turnips, as it now generally does, the Preparation of the Ground made for the Turnips, and the uſual twice hoeing them; if carefully done, will cut up every riſing Weed. To which, if we add the Turnips after over ſhadowing the whole Ground, and by that Means checking the Growth of any Weeds or Trumpery; all together, muſt keep the Ground pretty clear from them. But if there ſhould ſtill remain any Signs of this Evil, the Farmer may turn up the Soil two or three Times to the Winter Froſts, before there will be Occaſion to ſow his Barley. The Method of managing which to the greateſt Advantage, will be mentioned when we come to treat of Turnips: and ſurely by ſome, or all of theſe Ways and Means, the Barley may be ſufficiently preſerved or cleaned from Weeds; which will be very advantageous not only in the growing Grain, but in the Caſe of Sheering or ſoon Houſing, Loading, Threſhing, and fitting for the Market.

After the well clearing of the Barley from Weeds, we may reaſonably hope for an eaſy and expeditious Way of Reaping, and getting it made ſafe.

Now there is a very wide Difference in the Manner of reaping of Barley, between the Practice of the North Country and the South Country Farmers: the former of which generally ſheer and bind, and ſhock it clean and carefully as they do their Wheat; by which Means it is kept from all thoſe Inconveniencies which frequently happen to it by its lying on the Ground, and being alſo expoſed to all the Inclemencies of Weather.

But as this is a Corn not ſubject to ſhed, and the South Country Farmers principal Concern is, to take effectual Care of their Wheat; they commonly mow it, and a Man will this Way cut two Acres a Day, which is certainly a much quicker Way of diſpatching it, and ſo far done at a much leſs Expence. After this, in ſome Places, they let it lie a Day or two, and then turn it; and after a Day or two more, as the Weather favours, and the Weeds are killed, they gather it in Cocks, as they uſually do Hay, and then load it.

In other Places they let it lie after it is mowed, till they apprehend it is dry enough to load, though it be many Days, and rake it both Ways on Heaps, turning it up a little before they load it. However, in thoſe Places where they meddle not with it till they are juſt ready to load it, they are very nice in laying the Ears on that Part of the Swaſh where the Scythe points out, and is the higheſt; which they apprehend keeps it hollow, and lets the Wind under it to dry it: and they are alſo careful in keeping the Ears even together when they rake it. In ſome Places they have Forks with three large Tines, two under, and one riſing a good deal above it, by which they ſhove the Barley both Ways on an Heap.

A Reverend Author calls theſe laſt Ways, "The lazy and ſlovenly Cuſtom of the South," but I rather attribute it to the want of Hands in the South, where they have much greater Corn Harveſts than thoſe in the North.

The Chelsea and Fulham Farmers, who are thought to excel in the Management of this Grain, will, in a dry Time, ſometimes cock it in a Morning, whilſt the Dew is on it, to give it a little Sweat; and a little Rain on it whilſt it lies in the Swaſh, is thought rather advantageous than prejudicial to it. Some mention their letting it lie abroad as giving it a finer Colour.

Of the Produce and Advantages of Barley.

A late ingenious Writer mentions the common Produce of Barley to be, Two and a Half or three Quarters on an Acre; but that he has ſometimes known four Quarters on an Acre. I preſume, he here ſpeaks of what is got amongſt the middling Farmers, ſince he himſelf mentions much greater Quantities of Barley on an Acre.

Four Quarters in the common Courſe of Huſbandry, is generally reckoned a good Crop; but that allowing for the uſual Trouble and Expence of Fallowing, Dunging, and repeated Plowings, will not anſwer ſo well to the Farmer as is commonly thought; as will appear from the following Calculations: in which I ſhall allow three Quarters and an Half as a common Crop, and value the Barley at two Shillings a Buſhel, which is as high as has been

ſome Years, or as it is likely to be whilſt Wheat continues ſo cheap as it has lately been; Barley being uſually reckoned one half the Value of Wheat.

Now here the whole Produce would be two Pounds ſixteen Shillings, and deducting the Outgoings, that is, Seed three Buſhels, ſix Shillings; the uſual Plowings, Sowing, Harrowing, and Rolling, twelve Shillings; Weeding, Reaping, Threſhing, and Cleaning, the Straw being of little Value, eight Shillings; extraordinary Dung or Dreſſing, one Pound; Rent eight Shillings, in the whole two Pounds fourteen Shillings: ſo that there is very ſmall Profit to the Farmer, above paying him for his Trouble.

The common Profit of the uſual Produce of Beans and Peaſe is much better, as will after appear, and they help to improve the Ground for a Crop of Wheat; whereas it is generally allowed, that Barley impoveriſhes Land very much, and on moderate Computations a Crop of Oats, Clover, or Turnips, will be found to pay the Farmer better.

But by the late Improvements made by the new Huſbandry, a conſiderably greater Profit ariſes from a Barley Crop, taking the Produce to be the ſame; for the Loſs of the Fallow Year (the Rent of which was not reckoned to the Outgoings of Barley, as it might be) is anſwered by a Crop of Turnips, which will pay the Rent and what Manure is neceſſary, and the Huſbandry of them, by which Method much leſs plowing is neceſſary for the Barley; and by this Means, all Things conſidered, one half of the Outgoings to the preparing for Barley is ſaved, which conſequently is ſo much clear Gain to the Farmer.

But there is another very conſiderable Advantage may be ſaid to ariſe from Barley, according to the new Courſe of Huſbandry; which is, That Barley, of all Grains, is the beſt qualified to admit the ſowing of a beneficial Crop of Clover in it. And Clover being the beſt Preparative for a good Crop of Wheat, at an eaſy Expence, and Wheat paying generally much the beſt of all Grain, the producing or promoting ſo excellent a Crop, may reaſonably be allowed as an Advantage ariſing from Clover.

A very ingenious modern Writer indeed thinks the ſowing Clover with Barley, to be no good Practice; and is for ſowing it alone in AUGUST, thinking the ſowing it with Clover to be the Loſs of a Year: but in this he is certainly miſtaken, ſince by ſowing the Clover with Barley in the Spring, it plainly gains as much Time as it grows from the Spring when it was ſowed with Barley, till AUGUST, when it is ſuppoſed to be ſowed alone, and all is in the ſame Year.

And as to the Goodneſs of the Clover when ſowed with Barley, I have carefully enquired of ſome very ſenſible Farmers, their Opinions as to this Point; and was anſwered that they had as good Crops of Clover when ſowed with Barley, as could well grow: and I have ſeen ſome ſuch myſelf, and particularly one this Summer, at Mr. WOOD's, at BROCKSHALL, near KELVEDON in ESSEX; which being very good, I ſhall here give ſome of the Particulars relating to it.

Laſt Year he laid down a Field of twelve Acres with Clover, and this MAY, 1[illegible], he turned into it to eat it, twelve Horſes, eleven Cows and a Bull, ten Oxen, eight Heifers, and one Hundred Sheep, and thirty Hogs; and kept them there till about Midſummer, ſix Weeks at leaſt, and then ſaved it for Seed.

I ſaw it finely grown in SEPTEMBER, and about the End of that Month, he got from it four and twenty Waggon Loads of good Clover. It may be difficult, at preſent, to compute the Value of all theſe, but it cannot well be reckoned at leſs than Sixty Pounds.

But the Produce of Barley being frequently found much larger than what is above-mentioned, may well deſerve ſome Conſiderations about it.

MILLER ſays it is very common to have ten, twelve, or more Stems from one Corn; and that he has counted ſeventy Stalks of Barley from one Root, which was tranſplanted.

In the Experiments mentioned before from the Philoſophical Tranſactions, the three Spires of Barley ſteeped there as before-mentioned and ſet at two Foot diſtance, had ſixty, ſixty-five, and ſixty-ſeven Stalks apiece from their ſingle Grain and Root, with every one an Ear on, and about forty or ſomewhat more Corns apiece in them (which, at forty in an Ear, amounts to ſeven Thouſand ſix Hundred and Eighty Corns from the three Grains; being above two Thouſand five Hundred from each ſingle Grain) this great Succeſs the Author thinks proceeded not ſo much perhaps from the Grain, having been ſteeped in any Liquors, as from the Fertility and Goodneſs of the Soil, and their competent Diſtance one from another.

The ſame Gentleman further obſerved, that new Shoots continually ſtruck up from the Roots; ſo that here, if the invigorating Heat of the Sun had not been cooled and weakened by the Approach of the Winter Seaſon, there would have been continually new ripe Corn, and empty Ears on the ſame Root *.

Now this may afford Matter for many curious Obſervations to be made by the ingenious, who have turned their Thoughts to Affairs of this Nature.

* *Philoſ. Tranſact.* vol IV. 2d part, p 310--311.

But to conſider what MILLER mentions, and take his loweſt Eſtimate of ten Stems to one Corn, and twenty Corns in a Stem; that on the Suppoſition that only one Buſhel of the Seed Barley grew, would be two Hundred Buſhels for one, or twenty-five Quarters to an Acre; which is a Produce ſcarce to be much expected, however curious the Huſbandry may be: though undoubtedly it may be much improved from what it now commonly is.

For if ſuch great Produce be feaſible, the Want of it muſt ariſe either from the not having good Seed, and the not ordering it well, or from the not giving it Compaſs of Ground enough to grow in; or from the Ground not being properly prepared for it.

The two former may be eaſily remedied, by common Care, with a very little or no additional Expence; and as to the proper Preparation of the Ground, that ſhould be ordered in the beſt Manner, whether you ſow your Corn thick or thin, in the common or in the Drill

Way, or if you ſet it. And ſuch good manageing of the Ground can be no great Addition to what every good Farmer lays out in preparing his Ground for Barley, a Crown extraordinary would go a great Way, either in providing any ſteeping, or in bringing the Land to any Degree of Fineneſs, and indeed in both.

This Author mentions, That the Barley Corn which produced the moſt Grain was tranſplanted; and under the Head of Wheat I have mentioned ſeveral Advantages ariſing from that Method of Management, which I ſhall enlarge on farther hereafter; and the ſeveral Advantages that may ariſe to them thereby, which I apprehend may be in ſeveral Particulars equally applicable to Barley, and ſeveral other Species of Corn, and many Vegetables as well as to Turnips.

How far ſuch a Procedure may improve the Grain or Vegetables tranſplanted is yet uncertain, but may very well deſerve the Conſideration of the Curious, and the trying it in various Particulars; for to name only the Improvements made in the now ſo much valued Aſparagus, which is known to grow wild in the Meadows in ſome Parts of Engdand, and there is not eatable. It hath undoubtedly obtained its delicate Taſte from the ſeveral Tranſplantions, and different Methods of Management it hath met with under the Gardener's Care. We are all ſenſible what Changes appear in Barley, when made into Malt, what Alterations are made in the Flour of Wheat by the Baker, when he improves it into Bread; and the Changes of Milk into Butter and Cheeſe, by the Methods uſed in making them, were they not ſo common would be Matters of great Surprize to us.

There are ſeveral Inſtances of very great Produce of Barley. Platt's Friend plowed twenty Acres of Graſs Ground, after croſs plowed it, and harrowed it three or four Times to kill the Graſs, and mingle the fat with the lean, and ſowed it in the Beginning of March, and had thirty Quarters per Acre, and ſold it that Year at four Shillings per Quarter.

Sprat Barley has often produced ten or eleven Quarters when ſowed in March, tho' other Soils have produced but three or four.

To which I ſhall only add, that M. Nunn, in the County of Essex, had the laſt Year a large Field of Barley, which together produced eight Quarters per Acre. This is certainly very good yield, and what Land proper for Barley, with good Management, may reaſonably be thought to produce in Quantities, in a good Courſe of Huſbandry.

Of RYE.

Rye has been generally thought the next beſt Bread Corn to Wheat, and accordingly was formerly very much uſed for that Purpoſe, and is ſo ſtill in ſome Places; ſometimes alone, but then it has a peculiar Sweetneſs, which is generally diſagreeable to thoſe who are not uſed to it, and ſubjects many to Cholicks and Looſeneſſes, and the Bread made of it is black and heavy.

But a ſmall Quantity of it was formerly, and ſtill is in ſeveral Places, mixed with Wheat in the making of Bread, on Account of its keeping the Bread moiſt, and then is attended with no ill Conſequences, but is rather thought to render the Wheat more tender, freſh, and agreeable to the Taſte. And it was the more cultivated on Account of its being the Product of barren, gravelly, ſandy Land, which was then thought capable of producing nothing elſe, or very little worth the Farmer's Care.

The common or Winter Rye requires a Summer's Fallow, and more Expence and Trouble in the Management of it, then it is found to anſwer well; ſince the great Improvements made of thoſe dry ſandy Soils proper for it, by the Advantages made of ſuch Sort of Soils, by the ſowing of Turnips, and ſeveral artificial Graſſes, and the great Profit made by them; and from the ſeveral Species of Corn, they give the Farmer an Opportunity of raiſing much more advantageous than Rye: this muſt, on Courſe, ſink it in the Huſbandman's Eſteem, and make it in general to be much leſs regarded.

There are two Sorts of Rye.

Firſt, The common or Winter Rye.

Second, The leſſer or Spring Rye.

The firſt Sort is what is uſually propagated amongſt us, and generally on ſuch dry barren Land as is above-mentioned, where better Corn will not grow.

The ſecond Sort, or ſmall Rye, is to be ſown in the Spring, about the ſame Time when Oats are. It is apt to run into Straw if it prove a wet Seaſon, and this Sort is generally lighter than the other; however, it may be very conveniently uſed where Wheat or other Autumn Crops have miſcarried.

Two Buſhels are commonly allowed for Seed to an Acre, and four Loads generally reckoned a middling Crop; and it uſually carries equal Price with Barley, and about one half of the Price of Wheat.

In ſeveral Places they ſow Rye together with Wheat on the ſame Ground, and then it is called Maſlen, that is, Miſcellane, and will then bear a Price in Proportion to the Quantity of Wheat which is mixed with it.

The beſt Judges think this Sort of Huſbandry to be a very ill one, ſince as the Rye is ripe before the Wheat, and muſt ſtand till they are cut together, the Conſequence muſt neceſſarily be, that the Rye will ſhed a good deal of its Grain; and what is more, the Grains when ſo mixed ſeldom make a Bread that thoſe Perſons can well bear, who have been uſed to Wheat. But the Rye producing a Spirit, it is now ſaid to be much uſed for that Purpoſe, and ſo far may ſave the Wheat; though I doubt ſuch a Uſe of it will prove no great Advantage to our Country.

Rye is a quick Grower, and for that Reaſon the common Sort, as well as the other, ſometimes is ſowed in Spring, when Wheat miſcarries, and has anſwered Expectation: and the ſmaller Rye (as before-mentioned) is very proper for this Purpoſe, as it is uſually ripe at the common Times of Harveſt. The common Sort is ſometimes ſowed ſo late, in order to be plowed

in to fertilize the Ground for a better Species of Grain.

But there is a another more beneficial Proſpect of ſowing it in Autumn, which is, in order to provide Food for Ewes and Lambs in the Spring, when Turnips and Coleſeed are gone, or have failed, and before any other Sorts of Graſſes are grown to ſupport them: and it may be ſowed for this Purpoſe either on Land prepared particularly for this End, or on the Wheat Land after the Corn is carried off, or on other Stubbles when plowed up, or where Turnips have failed, and will probably anſwer Expectation, whichever Method of Management is taken with it for this Purpoſe.

It is certainly the beſt Proof of a Man's being a good Farmer, when he is known to provide proper and ſufficient Food for his Cattle and Sheep for the whole Year in general, and alſo has a further particular View for a ſecond Proviſion for his Ewes and Lambs, in caſe any of the former intended Sorts ſhould miſcarry.

All this he may certainly generally do, if he will but carefully conſider the ſeveral reſpective Times. The common natural, and the ſeveral artificial Graſſes, or Turnips, &c. will continue at the latter End of the Year; and alſo when he may expect any of them to come into his Aſſiſtance in the Spring: and then think of, and provide ſuch other Supports for them in the Time. None of them are to be had in the uſual Courſe of Things, by ſowing either Turnips, Rye, or Coleſeed, by the Help of one or other of which (with God's Bleſſing) he need not much fear but he may have a plentiful Proviſion for his Stock all the Year round. For which Purpoſe Turnips (I apprehend) may be made much more ſerviceable than is at preſent commonly imagined, as I ſhall endeavour to ſhew when I come to treat of Turnips in particular.

It is for the Want of this Knowledge and Care, to provide Greens and Graſſes for their Sheep in the Winter and the Spring, that in many Places in the North they are obliged to prevent their Ewes from having Lambs, till they have natural Graſs on the Ground, to help them to Milk to ſupport them, which is often not till the End of April, and ſometimes not till the Beginning of May; and then they are obliged to eat their beſt mowing Grounds ſometimes to the twentieth of May, before they can turn their Sheep to the Commons, and ſave their Grounds for Hay. If a dry Time then ſucceeds, theſe Grounds are burnt up, and their expected Product of Hay from their beſt Land, wholly, or in a great Meaſure deſtroyed; to the exceeding Diſadvantage of the Farmers, and ſometimes to their Ruin.

And why may not Rye be ſowed for the Purpoſes above-mentioned amongſt Turnips, and anſwer the Farmer's Expectation, eſpecially as the Ground on which Turnips are commonly ſowed, is generally better prepared, and uſually of a better Nature, and in much better Heart than the Land commonly allotted for the Growth of Rye; eſpecially where Turnips are ſowed after the Drill Manner, or managed in the Method we ſhall after mention when we come to this Head.

In plentiful Years Rye may be given to Fowl, or Hogs, which laſt delight in it, and will feed very well on it, when ground, and made into a Paſte, but then they ſhould always have Water, and alſo a few Beans or Peaſe at the laſt, to harden their Fat, which is commonly very beneficial in moſt Methods of feeding them.

This Grain is very ſubject to grow in the Ear, if any Wet comes to it; and it will be ſoon damaged if any green Weeds are mixed with it, ſo that particular Care muſt be taken of it in both theſe Reſpects; both to let it have Time in the Field, to prevent the Weeds making it to give in the Barn, which will make the Corn muſty, and therefore it ſhould be houſed dry, and that as ſoon as ever you can get it ſo.

The keeping it in the Chaff, on a dry Floor, is adviſed for the preſerving it ſweet after it is threſhed; the dry Chaff imbibing any Moiſture which may happen. This Method has been mentioned for preſerving Wheat, and is uſeful in ſeveral other Grains.

Of the OAT.

The Oat is generally placed next after Barley, but is commonly eſteemed of much leſs Value, and is accordingly much leſs regarded and huſbanded; though, if we come cooly to conſider the ſeveral good Qualities it has, and the Profit it produces, and thoſe at how little comparative Expence, we ſhall find it equal to Barley in all Uſes but one, and ſuperior to it in many; and in Reſpect of the Expence and Trouble attending each, and the Profit they reſpectively produce, it will be found preferable to Barley, and perhaps to all other Grain except Wheat.

The Oat generally grows in all Countries, and almoſt in all Sorts of Land; but thoſe Writers are very much miſtaken, who, one after another, roundly affirm, that it will grow in poor Land as well as rich; indeed no Land can well be too rich for it, but whoever expects a good Crop of it from poor Land, will find himſelf ſadly diſappointed. There is one undoubted Proof of its doing well in rich Land, becauſe it is generally firſt ſown when the richeſt Fields and Meadows are firſt broke up (to take off what they call the Edge of the Soil) the Richneſs of which would make Wheat run too much into Straw.

How Oats will anſwer in a rich Soil, I experienced many Years ſince, on breaking up a rich Meadow of three Acres, inclined to moiſture, on a gentle Deſcent, which, with one plowing, and no farther Trouble, it being a dry Summer, produced Stems in general between five and ſix Foot high, and ſome above, and very well headed. And though Oats were then cheap, theſe black ones were generally thought worth fifteen Pounds; and ſome Gentlemen brought in ſeveral of them above ſix Foot high, which were hung up many Years in the Hall as Curioſities. This was clayey Ground, and ſome Lime-ſtone lay above it.

In the ſame Neighbourhood black Oats were ſowed ſeventeen Years ſucceſſively, in an undivided Field, but was ſeveral Times manured, and brought tolerable good Crops to the laſt.

This

This was Lime-ſtone Land, and lay on a Deſcent, and I apprehend might receive ſome Advantage from the Lands above it, by the Waſh deſcending from them.

The Oat is diſtinguiſhed from other Corn, by the Grain growing in looſe Panicles.

There are three principal Sorts of it.

1. The common, or manured White.

2. The black Oats: which are omitted in GERARD and PARKINSON, though in ſome Parts of ENGLAND they are more ſowed than the former.

3. The naked Oat: much ſowed in CORNWALL.

To theſe we may add two others, very conſiderable.

4. The red or brown Oats; and ſome, I ſuppoſe, reckon theſe the red and the gray, and all of them compriſe the large white POLAND Oat, under the Name of White; the Seed of it being brought from POLAND, gave it that Name. And as it degenerates here in a few Years, it is often brought new from thence. It is apt to ſhed after Rain.

The white Oat has undoubtedly the larger Kernel, and turns out more Meal in the grinding than the black Oat; the Meal of a Buſhel of the white being near three Pecks from the Miln, and that of the black but two Pecks; but then the white Oat requires richer Land, and will not bear Cold ſo well; and as to every other Article, but what they call the Yield, the black is equal to the white, if not ſuperior in ſome Particulars.

For the black Oat, as above-mentioned, does not produce equal Quantity of Meal as the white does, Buſhel for Buſhel; but the Meal of the black Oat is as white, or whiter than the other, and is certainly ſweeter. Notwithſtanding what is ſaid by two or three of our beſt modern Writers, the black is the moſt made into Bread, and the moſt eaten as ſuch, both in the Northern and ſome of the Midland Counties of ENGLAND, of any Sort whatſoever; and is generally allowed to do leſs Injury to the Ground than the others; and, I preſume, is much more generally cultivated in SCOTLAND, than either the common, white, or the POLAND Oat: nor does it need any Mixture of Wheat to make it wholeſome or palatable when properly made. Nor does it delight moſt in moraſs or fenny Ground, as Mr. LAWRENCE writes; ſince the Crop I had, as before-mentioned, was on very good Ground, ſometimes eaten, ſometimes mowed on a ſtiff Clay at leſs than a Foot deep, lying on a gentle Deſcent, and ſome little Lime-ſtone Land lying above it there are yearly vaſt Quantities of Acres of good black Oats got on Lime-ſtone Ground, which is well known to be very dry Land. But perhaps this miſtaken Notion concerning black Oats, may ariſe on Account of their hardy Nature, and for that Reaſon their being frequently ſown on ſuch Ground, where it is commonly thought no other Grain will grow. The naked Oats, when threſhed, will make Meal without going to the Miln, but it is not ſo good as the former Sorts.

The Uſes of Oats.

Oats being a very temperate mild Grain, are fit for almoſt all Manner of Uſes and Purpoſes any Sorts of Corn can be, and being an hardy Grain it will grow in almoſt any Soil, and that with the leaſt Culture of any Grain whatſoever being very prolifick will, all Things conſidered, be found the moſt profitable of any Grain whatſoever (except Wheat) which ſome think is not much inferior to in this Particular; and may, in one Senſe, be ſaid to be an Improver of Land, as it paves the Way for its producing other Sorts of Grain.

It is commonly known and obſerved, what great Fatigues and Labours the SCOTCH have frequently gone through, when ſupported only by a ſmall Quantity of Oatmeal, which is a manifeſt Proof of the Goodneſs and Spirit of that Grain that could enable Men to go through ſuch Toils and Labours; and it is very well known that the moſt of the Northern Peaſants have little elſe to ſupport them in their hard Labours, particularly in that of getting of Stone; in which Work I have known them to ſweat Day after Day, with no other Nouriſhment but Oat Cake (Bread) and Water; and the better of them with only an Addition of a little Butter and Cheeſe, and a little Whey or Buttermilk to drink, ſeldom taſting Fleſh Meat or any Malt Liquor whatſoever.

Oats, when malted, make a very pleaſant Ale, and are frequently uſed for that Purpoſe: and they are uſed in the Kitchen in a thouſand Particulars, in which the Flour is preferred to the Flour of all other Grains; and there is no Pretence to ſet up any other as equal to it, except Wheat, which to be ſure is to be preferred before it in many Caſes.

It is alſo exceeding proper for the feeding of all Sorts of Fowls, and Swine of all Sorts, makeing the ſweeteſt Bacon of all Feeds; though it is thought very adviſeable to give the Swine a few Peaſe, toward the End of their feeding, in order to harden their Fat.

The Excellency of Oats, as the beſt and moſt wholeſome Food for Horſes, is allowed by all; and that when they have been kept till they are thoroughly dry, there is no Danger of thoſe Diſtempers which commonly attend, and are frequently fatal to thoſe fed on Beans.

They are equally uſeful for the feeding the Cow or the Ewe, to help them to Milk, and to nouriſh their Young; and at the ſame Time will ſupport the Ox in his Labour, or feed him fat the Slaughter. And the Straw is valuable for Food for Beaſts, beyond that of all Grain, and when ſome of the lighteſt Oats are left in it, and only the beſt threſhed out (which is called batting) it is thought very good Food for Beaſts; and Packs of Hounds, and all other Dogs, are commonly fed with Oats, when ground down.

Of the Soils proper for Oats.

As to the Soils, it has been mentioned that they will grow on all, and do very well on moſt, where a Crop of Corn can be reaſonably expected; yet Oats certainly do beſt on the beſt Ground,

Ground; for which we may appeal to common Experience, when they are ſown at the firſt breaking up good Ground, or when the Ground is well manured for them, which is common in the North; and in the Inſtances before, and which will be mentioned hereafter, alſo fully confirm the Truth of this.

Oats will do with the worſt Tilths, in the pooreſt Ground of any Grain, and very ſeldom have that Culture they well deſerve, and will anſwer for in their Produce: dry Ground will agree with them as well as wet, as is abundantly manifeſt by the great Quantity of Oats got upon Lime-ſtone Ground: and the great Produce ariſing thence, ſome Inſtances of which are herein mentioned ſcarce to be exceeded in any other Place, and far beyond the Crops mentioned by our late Writers as the common Product of Oats. I have had very good Crops of them after Turnips eaten on the Land, without any other Manure, the Produce being from ſix to eight Quarters an Acre.

Of Seed Oats, and the changing them.

The Seed uſually allowed for an Acre is four Buſhels; but in ſeveral Places, they ſow ſix or more, where the Ground is poor, or where ſuch an ill Cuſtom has prevailed. In this Article of Seed, the Farmer ought to be careful in getting what is good, and changing it from different Sorts of Soils, as in any Kind of Grain whatſoever, ſince he will find it equally beneficial. It is ſeldom that Oats are ſteeped, nor do they ſeem to want it as to their certain growing: and as to any other Advantages that may accrue to them by ſteeping, the Reader will find them mentioned under the Head of Steeping, and the Practice of it muſt be left to his own Diſcretion.

There is a Saying mentioned, That a quick Man ſhould ſow Oats, and a ſlow Man Barley; becauſe Oats need not be ſown ſo thick as Barley, but according to the Quantity of Seed allowed to each; this is no certain Direction.

Formerly they uſed not to ſow Oats till March, but of late Years they commonly plow for them at the Beginning of February, and ſow and harrow them in from the Middle of February, and ſo on; and now apply to them in this Particular, the Saying, The ſooner in the Ground the ſooner out; and find by Experience, that their Crops are generally ripe ſooner than they formerly were when ſowed later. And as this is their principal, if not only Grain in many Places; they generally weed it carefully, but have not had the beneficial Cuſtom of Rolling it long practiſed amongſt them in the North; nor has it yet generally prevailed, though now found ſo advantageous to it.

Of Reaping.

In regard to the reaping of Oats, the North far exceed the South Country Farmers, ſince they generally ſheer their Oats as carefully, and as clean from Weeds as the niceſt Farmers do their Wheat; and ſome of them bind the Sheaves as they ſheer them: but others more prudently leave them open all the Day, by which the Middle of the Sheaf gets very dry; and then they bind them up, and ſet them in Shocks, ten or twelve in a Shock, as the Farmer pleaſes; two called hooders, being gently drawn over the Tops of, and covering the others, &c. they will ſtand thus many Days without any Damage; and in Caſe of any very ſevere Weather, will, on a dry Day, be fit to load ſo, that if the Farmer have but Patience, it is very ſeldom that Oats ſuffer in the Field; and if they be led moiſt, they ſuffer leſs in the Barn on that Account than any Grain whatſoever, both in Reſpect of the Nature of the Oat, and of the Straw. The uſual Price of Sheering is about Three Half-pence per Thrave, and the North Countrymen are very dextrous at this; and when they come into the South to work, as many of them do in Harveſt, excel the South Countrymen in the Article of Sheering.

If the ſowing be deferred long, as it ſometimes is till April, then it ſhould be well harrowed in; and in ſome Places the Wetneſs of the Land almoſt obliges the Farmer to the ſowing ſo late.

Of the Produce, and other Advantages of Oats.

Miller mentions Oats as a very profitable Grain, and that the uſual Produce is five and twenty Buſhels; though he has ſometimes known more than thirty on an Acre. This is a very poor Account of the Produce of this Grain, ſince four Quarters are common on very indifferent Ground; and ſix or ſeven is no extraordinary Crop; and ten Quarters are frequently had with only one Plowing without any further Trouble.

I am certain I had an Hundred Buſhels or above of black Oats on an Acre, as before mentioned, with only once Plowing, and that without any Rolling or Manuring whatſoever; and it is very common to have forty or fifty Thraves on an Acre; each Thrave conſiſting of four and twenty Sheaves, and each Thrave, if the Oats be good, and the Sheaves of the uſual Size yielding from one Buſhel three Pecks, to two Buſhels one Peck: ſo that an Hundred Buſhels on an Acre is nothing extraordinary, both in Derbyshire and Staffordshire on good Land. And I have known an experienced Farmer in Staffordshire had three Hundred Thrave of good black Oats on five Acres on good dry Lime-ſtone Ground, with only common Huſbandry, and once Plowing (as he told me himſelf.) This was thought a very good Crop, but not ſuch a one as to occaſion any Amazement, ſeven, eight and ten Quarters being very common. To which I ſhall add one Inſtance more; which, tho' nothing extraordinary to me, will appear ſo to thoſe who think four Quarters of Oats a good Crop.

The Inſtance I ſhall laſt mention is, that of a Crop of Oats of a pretty large Field of a Farmer in the Iſle of Mersey in Essex; which the laſt Year brought him eight Quarters and an Half of Oats an Acre through the whole Field.

This Crop followed one of Wheat, and he managed his Land after the following Manner:

It being a very dry Time after Wheat Harveſt, he ſet Fire to the Stubble, and burnt it off very clean; after gave the Field three clean Tilths, and laid it on a round Ridge (as they call it) all the Winter, and then ſowed it as uſual with Oats in the Spring, and had the Produce above mentioned.

The three Plowings may be thought an extraordinary Expence (and indeed is very unuſual for Oats) but where the Ground is kept in a good Courſe of Tillage; and a Man with two Horſes can plow two Acres, or at leaſt an Acre and an Half a Day, the Expence is nothing extraordinary. An Acre not engaging ſuch a Team above two Days at the moſt for three Plowings; and a conſiderable Benefit to the enſuing Crop may be reaſonably expected, as well as the keeping the Land ſweet and clean from Weeds, is the great future Advantage that will be to the Land in the ſucceeding Crops of whatever Kind they be.

Another Writer ſays, "Moſt People ſow Oats "for two Reaſons, one becauſe they lower the "Strength of new Ground, and the other to "give old Ground the Benefit of Change of "Seed;" and yet this ſame Perſon allows five Quarters on an Acre as a common Crop, and ſays, "He has known nine, and that they have "often ten Quarters an Acre, when they Ma-"nure the Ground for Oats;" ſo that by his own Confeſſion and Reaſoning, a common Crop of Oats far exceeds a common Crop of Barley. And where the Land has the ſame Manuring for Oats which Barley requires, it hath the Crop of Oats double to that of Barley; and, conſequently, is preferable to Barley, for the bare Profit they will reſpectively bring to the Farmer, the Prices of the one and the other not being uſually much different. But this Preference of Oats will appear more, after we have conſidered the Advantages of Oats, which have by ſeveral been on the whole frequently eſtimated equal to the general Produce of a Crop of Wheat.

The Advantages of Oats.

There are three very conſiderable Advantages the Oat claims, which no other of the white Corns do; nor, indeed, any other Sort of Grain common amongſt us, has any Pretence to vie with it in, with the leaſt Appearance of Reaſon.

The firſt is, that it will grow and pay frequently very well on thoſe Lands, which will not anſwer to the Sowing any other Sort of Grain: and this Advantage is generally allowed the Oat by all who write on this Subject; which they have rather carried to an Exceſs in its Behalf, when they ſay, It will grow in all Countries, and on all Lands; that there is no Ground too rich, or too poor for it; which cannot be ſaid of any other Grain whatſoever. So that in this Reſpect Oats have undoubtedly the Advantage above all other Grain whatſoever.

The next Advantage of the Oat is, That it is pretty certain to bring a very good Crop, on the firſt breaking up any good Meadow or Paſture Ground; of which we have given ſome Inſtances before, and might eaſily add numerous others: but this Advantage is alſo generally allowed to the Oat, that it in this Caſe commonly produces a very good Crop, without any Manner of Expence but of one Plowing and Sowing. And alſo prepares the ſame Ground much better than it could be any other Way for a ſucceeding good Crop of Wheat, which is ſo eagerly ſought for in all the Corn Countries.

The third particular Advantage of the Oat is, The Benefit ariſing from the Goodneſs of the Straw for Food for Cattle; for which Uſe it is uſually ſold in our North Countries, from Four-pence to Six-pence a Thrave; and, conſequently, tolerable good Crops may on a Medium be valued at twenty Shillings per Acre, in which no other Straw can be compared to it as to the Sweetneſs of it for Food; nor indeed is there any other Straw but Wheat of any Value to ſpeak of. And though Wheat Straw excels it for Thatch, yet Oats will laſt ſeveral Years for that Uſe; and, on the Whole, may juſtly have its Straw reckoned amongſt the Excellencies belonging to the Oat.

There is another Advantage it certainly has over the two moſt eſteemed Sorts of Grain, Wheat and Barley, which is, That it is got with leſs Plowing, requires not ſo fine a Tilth, and not near ſo much Manuring in general, as they do to procure an equal reſpective proportionable good Crop; all which will be ſaved in the Farmers Out-goings, and will enter into every wiſe Man's Conſideration. It is not ſubject to Smut, ſo prejudicial to Wheat, and ſuffers the leaſt in a wet Seaſon of all Grain, being as ſoon dry as any, and ſuffering the leaſt when houſed wet.

And as to the general Advantages of other Grains, it may be ſaid to ſtand at leaſt with them on a level; for, it gives the Farmer an Opportunity of varying his Grain, which is one of the general Advantages of Huſbandry; and, particularly in what is called the new Huſbandry. It ſeems not to diſlike the following any other Grain; and to anſwer any Huſbandry which the Situation of the Ground, as to its Goodneſs, will afford it.

It alſo allows a long Time after other Crops are got off the Ground, for the meliorating the Land, by the Benefit of its lying expoſed in Fallows, and to Winter Froſts, before it is neceſſary to ſow it: the Advantages of which are very well known.

Laſtly, It is ſuperior to all other Grain but Barley in its Capacity of receiving the foreign Graſſes to be ſowed with it, from which a great Part of the Advantage of all the new Huſbandry particularly depends, of which we ſpoke before under the Head of Barley, and therefore ſhall not repeat it here, but ſhall only ſay, The Oats has a Right to every Thing ſaid advantageous of Barley in that Reſpect.

A late Writer gives the Oat the Preference to Barley in this Point, in the following Words; "An Oat Crop is the propereſt Corn "of all others, to ſow any of the Graſs Seeds "amongſt, if the Ground is in Heart, becauſe "the

" the Stalks of Oats are apt to ſtand ſtiffer " than Barley, and thereby the Crop of Graſs " is in leſs Danger of being ſpoiled."

This Author juſtly obſerves, " If the Ground " is in Heart," ſince the Land ſet apart for Oats is very ſeldom ſo well manured for Oats, when the Graſs Seeds are to be ſown in it, as it is for Barley; and, conſequently, a leſs valuable Crop of the Graſſes is to be expected when the Land is in a poorer Condition: but the right Way of judging is, when they are in the ſame equal Condition of Goodneſs; and then to ſee, which would anſwer the beſt. But even in this Caſe I would not inſiſt on its Superiority to Barley in this Particular, but only ſay it is equal to it: for the Oat has other ſufficient Advantages above the Barley, as may appear from what is before mentioned here, and above of its Uſes, and from what will be ſeen in the following Calculation.

A Calculation of the Profits of Oats.

In this Calculation I ſhall not take the Produce of a Crop of Oats at nine or ten Quarters, which frequently happen; but at ſix Quarters, which may generally be reckoned a good Crop.

Eſtimating the Value of a Buſhel of Oats at one ſixth Part leſs than the Value of Barley, the Oats will then be to be reckoned at twenty-pence the Buſhel; which being thirteen Shillings and four-pence per Quarter, ſix Quarters will amount to juſt four Pounds for the Produce of the Oat; and the Straw will above anſwer the Sheering, Loading, Threſhing and Cleaning. The other Out-goings will generally ſtand thus: Seed four Buſhels, ſix and eight-pence; Plowing, Sowing, Harrowing, and Rolling, ſix Shillings and eight-pence: Rent reckoned as the Barley, eight Shillings. And though Oats have very ſeldom any Manure laid on the Land in particular for them; yet, in this Caſe, I will allow ten Shillings and eight-pence for Manure. So that the Out-goings will be in the whole, all Expences and Trouble allowed for, one Pound twelve Shillings; which, deducted from four Pounds, the Produce of the Crop of Oats, there will remain two Pounds eight Shillings clear Profit to the Farmer. Whereas the clear Profit of Barley, all Out-goings allowed for, amounted to about eight Shillings. So that this Way there is two Pounds Difference. And if Oats are ſometimes leſs, ſo is Barley frequently: and if Barley ſometimes exceeds four Quarters, Oats much oftener exceed ſix Quarters. So that on the whole, the Oat ſeems to have a clear Right of Preference to the Barley, as to the Profit accruing to the Farmer from them reſpectively: and, on an Average, the Oat will be found to produce twelve or more for one; and few other Sorts of Grain can pretend to do more.

In this Calculation of the Profit, I reckon on the white Oat.

Moſt of our Writers, (though many of them Perſons of very good Underſtanding) inſinuate the great Advantage of Oats to be, that they would grow in the North, where nothing elſe would; and even including in that ſome of our very Midland Counties, as DERBYSHIRE and STAFFORDSHIRE. It may not be amiſs to conſider this Matter, that the Farmer may not be diſcouraged from attempting to raiſe good Corn, Fruit and Vegetables, in whatever Part Providence has placed him; provided he act with Prudence, and engage not too deep at once in any Trials of this Kind.

It was long before it was known, that a Cherry would grow in ITALY, or a Grape in FRANCE; much leſs either of them in BRITAIN. And the great Sir WILLIAM TEMPLE, who lived within Memory, was ſtrongly of Opinion, that no better Wall Fruit than a Plumb would grow beyond NORTHAMPTON, though the contrary is now well known to the Nation.

To come from Generals to Particulars, which ſtrike the deepeſt. It is not many Years ſince; in the Pariſh of ASHBOVER, near CHESTERFIELD, in the County of DERBY, no Wheat was got, though it is now in great Plenty; and all owing (as I have been credibly informed) to a Woman married from a Corn Country, who perſuaded her Huſband to try, as there was Lime enough for Wheat; which proving ſucceſsful, encouraged others, and has ſpread all around.

Another Inſtance fell within my Obſervation, for going once directly from CHESHIRE to LONDON, I ſaw Barley cut and in the Shock, between WINNINGTON BRIDGE and NORTHWYCH; and no other Corn of any Sort cut in all the Way to LONDON, though I took particular Notice.

To which I ſhall only add from Mr. HAMILTON, who reſided ten Years in ENGLAND, and made it his Buſineſs to inform himſelf in Huſbandry. " They there had as good and as " large Carrots, Cabbage, and Parſnips, as ever " he ſaw in ENGLAND."

But having paved the Way for a favourable Hearing by theſe Inſtances, this being a Matter of almoſt general Concern, I ſhall here take the Liberty to enlarge a little on this Point.

Corn, Vegetables, &c. principally owe their Excellence to the Nature of the Soil, the Goodneſs of the Air, a proper Situation, Shelter, and a kindly ſuitable Heat: all but the laſt are undoubtedly to be had in all Parts of the Kingdom, as well as near LONDON; as might be eaſily proved in particular. And in order to ſet the Point of Warmth in a proper Light, I will give the Tables of the different Quantities of Heat, at different Parts of the Kingdom, as they have been calculated by thoſe who are thought well verſed in Affairs of that Nature; and will after make ſome Obſervations on this Subject.

Tables of the Quantity of the Sun's Heat at Noon, when it is vertical at the Summer Solſtice, the two Equinoxes, and the Sun's Entrance into Taurus and Virgo, for the ſeveral Latitudes from 44° to 56°.

In

In theſe I ſhall mention only thoſe we are concerned in, beginning at the Lizard Point, and ending at EDINBURGH.

Degrees of Latitude	Names of Places.	Heat, *June* 10.	Heat, *Ap.* 10. and *Aug.* 12.	Heat, *March* 10. *Sept.* 11.
Vert. Sun	—— ——	100	100	100
50	The Lizard	71	49	26
51	—— ——	69	47	24
51½	LONDON ——	68	46	23½
52	—— ——	67	45	23
52½	YELVERTON, in NORTHAMPTONSHIRE	66	44	22½
53	—— ——	65	43	22
53½	LINCOLN ——	64	42	21
54	—— ——	63	41	20
55	NEWCASTLE ——	62	38	19
56	EDINBURGH ——	60	37	18

The Gentleman who procured theſe Tables and Calculations, very juſtly obſerves, that tho' they ſhew the real Difference of the Sun's Meridian Heat, in different Latitudes, yet they do not account for the greater Number of Hours of the Sun being above the Horizon, which a Northern Latitude has more than a Southern one; which is the principal Thing as to our preſent Purpoſe.

And therefore he aſſures the Reader, in general, and by one round Number, That during all the Summer Seaſon (the Time of ripening Fruits) betwixt the two Equinoxes, there are no leſs than one Hundred Hours of Sunſhine at DURHAM, more than there are at PLYMOUTH; as might eaſily be ſhewn by a particular Table.

There are ſeveral other Particulars which, under this Head, may be taken into Conſideration, in Behalf of thoſe who live Northward, which may ſet them on the Level with, or give them a Superiority over ſome of the more Southern Countries; beſides what this Author mentions of the greater Number of Hours of Sunſhine they enjoy, more than theſe as above-mentioned.

As firſt, the different very good Sorts of Soil frequently found in the Northern Counties, which all allow to be a conſiderable Article in this Point, when compared with ſeveral other Sorts of Soil in the South.

Another Advantage is, that in ſeveral of the hilly Countries, which are the moſt ſubject to be contemned, there are frequent Vallies ſo well guarded by the Hills, from all Manner of unkindly Winds and Storms; and of ſo good a Soil by Nature, and the Produce of which is ſo promoted by the Reflection of the Sun's Heat, by the Poſition of the Hills, that they are as forward as any Places in the South; and allowing them the ſame Culture, would have as early and much ſweeter Produce than the Ground near LONDON would with the ſame Management, and would produce all Sorts of Vegetables, and moſt Sorts of curious Fruits, equal to thoſe in the Southern Countries.

I could name ſeveral particular Places which would anſwer what is above-mentioned, but ſhall rather take Notice of thoſe more generally known.

CHATSWORTH in DERBYSHIRE, the Seat of his Grace the Duke of DEVONSHIRE, though far from being a kindly Situation, or placed on a good Soil, is managed ſo as to produce moſt Things near equal in Goodneſs to thoſe in the South.

And HADDON, two Miles from it, the antient Seat of the Duke of RUTLAND's Family, is on a better (Lime-ſtone Soil) and before it was neglected, and indeed deſtroyed, produced as good Vegetables and Fruit, as then were found in moſt Parts of the Kingdom. And ſtill, though only under a common Gardener's Care, it produces admirable Vegetables and Fruits, which many Years were ſent to BUXTON or CHATSWORTH. But of late Years BUXTON, which was always thought to be placed in as barren a Place, and as unkind a Situation as could well be imagined, and which, within my Memory, uſed to fetch Greens and Vegetables for twenty Miles round, to furniſh the Gueſts with what was proper for them; even this barren Place is now ſo managed, as to produce every thing neceſſary and uſeful, and many Things curious for the numerous Gueſts who reſort to it.

Now theſe Inſtances, with what was before-mentioned, will undoubtedly ſhew that the Northern Countries are capable of producing the Grains and Vegetables which ſome would appropriate only to the South.

The whole Earth is reckoned naturally barren, as to the Production of Corn; and clayey Land, which was uſually eſteemed the moſt unkind of all Soils, by proper Culture, is brought to produce the beſt Wheat, the beſt of all Grains.

A Reverend Gentleman, who made this Point his peculiar Concern declares, that after living in the Middle or Southern Parts of ENGLAND, the firſt Part of his Life, on his Removal into the Biſhoprick of DURHAM, he never eat more or better Fruit, even of the later Kind (except Grapes) than after he came into that Biſhoprick; and thinks a Degree or two will have little Influence as to Fruit, in Compariſon of the Soil and Situation; and that, was there as good Markets in the North as at LONDON, all the curious Things ſo much admired at LONDON, would be equally raiſed there. And the Argument is much ſtronger for the well raiſing of Corn and Vegetables, than for the raiſing curious Fruits.

So that on the whole it appears, that the greateſt and moſt conſiderable Difference of Heat and Warmth, for ripening Fruit, Corn, or other Vegetables, ariſes principally from the Nature and Circumſtances of Soil and Situation, from a Place lying on the South or North Side of a Hill, from its being on the Top of a cold Hill or in a Vale; from its being ſheltered or not ſheltered from Winds; from its lying on a cold Clay, or on a warm Sand or Gravel. Theſe are the Circumſtances chiefly to be regarded.

For it is very plain that a Garden, or Land lying on an eaſy Slope on the South Side of an Hill, receives more of the Sun's Rays than the ſame Quantity of Ground lying on a Plain, and hath more real Advantage of Heat from the Sun, than ſeveral Degrees of Southern Latitude would give it, cæteris paribus. And the Argument

ment is ſtronger ſtill, if the Ground in the South ſlope to the North; the ſame Thing is to be ſaid with Reſpect to cold Clays, and warm Gravels, they being guarded or not guarded from Winds and ſo on.

As to the Inconveniencies which are common to the whole Iſland, ſuch as the Inequalities of our Seaſons, the Violence of our Winds, and the ſudden Changes of our Weather, they cannot be ſaid to be more prejudicial to the North than the South; but on the contrary, according to Dr. DERHAM's Hiſtory of our great Froſt, the South ſuffered then much more than the North, as he and other Obſervers mention, of which they give numerous particular Inſtances.

Theſe Obſervations may not only ſerve to reconcile the Farmer and others to a Northern Situation, but alſo encourage them to equal Induſtry and Application, with thoſe who are ſituated more in the South; ſince they find, that if they act with equal Judgment, they need not fear but they will meet with equal Succeſs.

Hence alſo they may draw many uſeful Obſervations, as to the Manner of ordering their Grain and their Roots, from the ſeveral Advantages they may reap from the different Natures of their Soils, and the different Poſition of their Grounds, as to North and South, and the proper Shelter they may ſeverally enjoy, or which may be provided for them; it being commonly obſerved by Farmers, that the one Side of a Corn Land, in many Situations, is much thinner of Corn than the other. And the ſame may be ſaid of Fruits, and may be applied in numerous other Inſtances.

To return to Oats, there is one other Thing I ſhall obſerve relating to them, which is, about the Manner of keeping them.

Of keeping of Oats.

The Oat has one farther Advantage, that it may be kept the ſecureſt and in the eaſieſt Manner of moſt Sorts of Grain, if not of all Kinds whatſoever.

It was obſerved before, how little ſubject it is to receive Damage when houſed in the Barn, or placed in a Stack, on Account of the Nature of the Straw, which is both ſweet and dry, and the leaſt ſubject to be muſty of any Sort.

Oats will alſo keep very well when threſhed, and laid by in the Chaff, without any further Trouble or Care, provided they be not laid by wet, or wet be permitted to come to them, in ſuch a Degree as would ſpoil any other Corn whatſoever.

But the principal Method of ſecuring the Product of this Grain, where it is uſed as Bread, is by firſt grinding it, and making it into Meal, and then putting it cloſe down in an Ark of Wood, where it will keep good many Years. This Method is ſo well known in the Countries where the Meal is generally uſed for Bread, that there is ſcarce a Family but has one of theſe Arks kept under Lock and Key, either in the Dwelling Houſe, or in ſome Building adjoining to it, or in their Barns. In which thoſe who are able keep a ſufficient Stock for their Families, from Time to Time; and thoſe who can keep it for a riſing Market, oft ſell it at the ſame proportionable Profit as thoſe do who can ſave Wheat till it riſes. It is very common to put four Hundred Pecks of Meal into one of theſe Arks.

Of the BEAN.

The Bean was well known to, and much eſteemed by the Antients; but Mr. RAY obſerves it is diſputed amongſt the Botaniſts, whether their Bean was the ſame which is now uſually ſowed with us; ſince it is very certain, from many Places both of THEOPHRASTUS and DIOSCORIDES, that the Bean of the Antients was ſmall and round.

Yet, as he obſerves on the other Side, it ſeems incredible, that a Pulſe ſo common, and of ſuch daily Uſe, ſhould be utterly diſuſed, or change its Name, and have another ſubſtituted in its Place, without any one taking Notice of it.

But if a Conjecture may be allowed in this Caſe, the Bean of the Antients, as deſcribed by Mr. RAY to be ſmall and round, and which was formerly ſo much eaten, ſeems more like what is now called the Magazan Bean, after-mentioned, than that we moſt commonly ſow. And as to the Uſe of its being loſt, or the Name being changed without any particular Notice taken of it, ſo many Things of that Kind have happened, in the Succeſſion of Ages, that it cannot occaſion much Wonder.

Of the Sorts of Beans.

Theſe are principally two.

The leſs or common Field Beans, or Horſe Beans, generally ſowed in the Fields. And

The great Garden Beans of various Sorts and Colours, for the moſt Part white, but ſometimes red.

PYTHAGORAS forbad his Diſciples meddling with Beans; what he meant by this was, that they ſhould abſtain from meddling with the Affairs of the Republick; becauſe the Antients uſed Beans in the electing their Magiſtrates as Diſtinctions when they voted.

The Bean has a papilionaceous Flower, which is followed by a long Pod, filled with large Seeds, the Stalks are firm and hollow, and the Leaves grow by Pairs, and are faſtened to a middle Rib.

The common Farmers ſeldom ſow any but the ſmall or Horſe Beans in the open Fields: but as many of thoſe called Garden Beans are now much cultivated in the Fields, both near LONDON, and in ſeveral other Places, and are equally capable of being managed after that Manner, and that with greater Advantage to the Owner, the one as well as the other, deſerves a Place in ſuch a general Undertaking as this, for the Farmer's Intereſt, whoſe Advantage ought to be particularly regarded in every Point. If it be rightly conſidered, in reality, a Garden is but a little Field well cultivated, and what we call a Field, but a great Garden capable of all the ſame Methods of Management. Which large Field, managed with the ſame proportionable Induſtry, Manure, and Care, will produce a proportionable Profit, both in the Caſe of Beans, and alſo of all Sorts of Vegetables, as will evidently appear to any Perſon who will but walk into the

Fields about Chelsea, Fulham, Battersea, and ſo on.

The principal Varieties cultivated are theſe:

1. The common Field Bean; the Culture of which will be treated of hereafter.

2. The early Liſbon, or Portugal Bean; which is the Sort moſt commonly ſowed by the Gardeners, one of the earlieſt ripe, and principally valuable on that Account; being, in Reality, a coarſe Sort of Bean. It is often ſown in October or November, and does not require ſo much Sun, as a proper Shelter; which tall Hedges or Trees, when properly placed on the Eaſt, North, or Weſt afford. For it is now well known to the Curious, that both Grain and Vegetables ſuffer moſt in the hard Seaſons, when they are expoſed to the being ſometimes frozen or covered with Snows, and then thawed or uncovered, which prove the moſt deſtructive to what is early of any Weather whatſoever.

Derham obſerves, "That Snow preſerves "Bodies thirty Years uncorrupted, and guards "the Corn againſt cold piercing Winds,* and in his Hiſtory of the great Froſt,† he obſerved, "That many ſmall Fields of Wheat eſcaped "pretty well, where fenced with thick high "Hedges againſt the cold Winds; eſpecially "where they were covered long with Snow. "Thoſe ſuffered more where the Winds blew "off the Snow; and thoſe were the beſt Wheat "which were on ſuch Pieces as lay on gentle "Deſcents, facing the Weſt or South Weſt; "eſpecially when guarded on the Eaſt Side "with a Hill, or a Wood, which fenced off "the cold piercing Eaſterly, and North Eaſterly "Winds."

* *Phyſico Theol.* page 34.
† *Philoſ. Tranſact.* vol. IV. page 122.

Several other curious Perſons confirm the ſame, and obſerve, "That Eaſterly Winds do "more Miſchief ſometimes in Spring after a "few favourable Days, than all the Winter "Froſts; ſince by ſudden Changes of the "Weather, the Paſſages in Trees and Plants "are ſtopped; the crude Sap ſetting, becomes "a Diſeaſe in Trees equal to that of Chilblanes "in Juvenile Blood, which ſometimes takes "whole Trees, and ſometimes Branches only.‖

‖ Vol. II. page 158. 754.

Now this being a Matter of Conſequence, and applicable to ſo many Caſes, I thought it might properly be inſerted here once for all; both for the Sake of the Farmer in the Field, and every private Perſon in their reſpective Gardens. We doubt not but they will take the Advantage of this Remark, by being careful where they ſow any Thing curious, or intended to be early. And alſo to be very cautious not to truſt to a few flattering Days in the Spring, but to wait in nicer Things till the Mulberry puts forth its Leaves before they expoſe them.

It was very common to plant early Beans, and Things of that Kind under Walls, that they might have the Benefit of the Sun: but the Reaſons above, and modern Experience, may inſtruct, that thoſe Situations are frequently fatal, and therefore moſt now rather chuſe to ſet them againſt Hedges, or Reed Hedges run along the Garden for that Purpoſe. And yet with the greateſt Care, and the deſired Succeſs, they will only be found about a Week or ten Days earlier than thoſe ſet in the Spring, and are not to be eſteemed of the beſt Kinds.

The ſmall Spaniſh Bean comes in quickly after the Liſbon Bean, and is a ſweeter, and will conſequently be preferred to the other.

The broad Spaniſh Bean is a good Bearer, and coming in before the common Sorts, is valuable upon that Account.

The Sandwich Bean ſucceeds ſoon after the Spaniſh, and is almoſt as big as the Windſor; is a plentiful Bearer, and a hardy Bean; and conſequently may be ſown much ſooner by a Month.

The Toker Bean is a great Bearer, and comes in about the ſame Time with the Windſor.

The Bloſſom Beans black and white, are very green when boiled, and very ſweet; but the Seed is ſubject to degenerate.

The Windſor Bean is undoubtedly the beſt of all for the Table; and, when gathered young, is the ſweeteſt and beſt taſted of all; and when they have Room, and a good Soil, they are plentiful Bearers, and very large.

Theſe are ſeldom planted till Christmas, becauſe they bear not the Froſts ſo well as ſome of the others, ſo they generally come in June and July in Abundance.

The Mazagan Bean is eſteemed the firſt and beſt Sort of early Beans now known. The Seeds are much ſmaller than thoſe of the Horſe Bean; and, conſequently, ſeem more agreeable to the Sort mentioned by the Antients.

If theſe are ſown in October under a warm Hedge, Pale, and ſo on, and earthed up as they riſe, they will be ready in May, and bear plentifully.

Theſe Seeds were brought from the Coaſts of Africa by the Portuguese, and from them to us, and brought hither as wanted. When the Seed is ſaved here they grow larger, but ripen not ſo ſoon.

Theſe ſeveral Sorts differ pretty much in Shape, require different Times of Setting, and vary in the Time of their Ripening, as well as in their ſeveral Taſtes: and alſo in their Qualities of bearing the hard Weather better or worſe. Notwithſtanding all which, the beſt Writers are of Opinion, that they are only ſeminal Variations, and that they are very ſubject to degenerate. For which Reaſon great Care ought to be taken of procuring proper Seeds; for I once had a Sort of Bean between the Liſbon and Windſor Bean, which was as early, hardy, and near of the Size of the Liſbon Bean, without the Coarſeneſs of the Taſte of it, in which it very much reſembled the Delicacy of the Windſor Bean: but miſcarrying in preſerving the Seed of it as good, and the Friend I had it from being in the ſame Situation, I never ſince could retrieve it.

Beans when about two Inches high, ſhould be carefully earthed up, and ſo as they riſe two or three Times; and, in very ſevere Weather, ſhould be covered with Fern, Peaſehaulm, or ſome light Covering, but to be taken off in mild Weather.

Theſe planting of Beans may be repeated once in three Weeks, and the leſs Care is neceſſary as they come later, and the leſs Seed. The ſet-

ting them at the greater Diſtance will do as they are ſet later. The Windſor Beans may be ſet in Rows at a Yard Diſtance, and at three Inches in the Rows, or rather farther off.

The after Crops ſhould be planted about a Fortnight Diſtance after each other, from FEBRUARY to the Middle of MAY, kept clear from Weeds, and 'tis well to keep earthing them up; and when they are in bloſſom to cut off the Tops of all, which will help to increaſe the Pods, and alſo to deſtroy thoſe Flies ſo pernicious to them: the later the Beans are ſown, the moiſter Ground they require; and it is proper to take off the Suckers, when the Beans are about a Foot high.

This may ſeem unneceſſary for the Farmer, but as ſeveral of theſe Beans are already got into the Field, and others gradually following them, we hope the Reader will receive this Account of them favourably.

Of the Seed, Sowing, and Steeping.

You ſhould take Care in the Choice of Seeds, particularly when brought from diſtant Places, or when had from Strangers, ſince the Crop muſt miſcarry if the Seed be bad; and where it is but indifferent, the greater Quantity muſt be uſed to anſwer for Accidents. And this Care is neceſſary and applicable in almoſt all Caſes, but being of the greateſt Conſequence, the mentioning it cannot be too often repeated.

There may be ſaid to be four Ways of ſowing, or planting of Beans.

The old Way of ſowing them in the Field was generally to plow the Ground, and let it lie ſome Time: then to ſow them in the broad Caſt-way, and harrow them in, which was ſeldom found to anſwer well; the Seed being too much expoſed to be eaten by Fowls, or burnt up in Summer by the Heat, for want of a proper Depth of Earth.

But of late they have generally ſowed the Beans under Furrow, by plowing them in with as thin a Caſt as poſſible; and, in very ſtiff Lands, they harrow the Ground after a Shower, when the Beans begin to peep, which helps to break the Clods, and let out the Tops. But great Care ſhould be taken not to plow too deep, for fear of burying the Seed; and to lay the Turf flat, not edge-ways, that the Beans may be covered with Mould; ſince if they lie hollow, they will be ſubject to grow mouldy and decay.

The ſecond Way is by the Drill Plow, of which Sort of Huſbandry the Beans are ſometimes capable; though a very ſtiff Soil, and the Make of the Bean does not ſuit it well. When we come to treat of Peaſe, we ſhall make ſome Remarks, what Objections are to be made to it, and how far it has prevailed.

The third Method is the ſetting the Beans by Hand, in Rows, in Holes, at about three Inches Diſtance. When the Ground is properly prepared, which the Women will do in many Places for Three-pence the Peck. This is a very moderate Expence; and will be ſaved in the Seed-Beans uſed this Way, in Compariſon of what are uſed in the common Method of Sowing. But in this Way I ſhould prefer the making the Holes with a Trowel, rather than a Dibber; which, though it gives a little more Trouble to do it, yet it prevents the Beans from laying hollow; and alſo leaves the Mould looſer about them, and ſo they will be better able to ſtrike freely into the Ground. It comes neareſt the ſowing in Drills made by the Hand Hoe, or by the common Plow; which may be reckoned, The fourth and laſt Way, both theſe are uſed by the Gardeners, who are very expert at the Hand Hoe, and will diſpatch a great deal in a ſhort Time, and plant the Rows at any deſired Diſtances, either to have the Interſtices left open for other Vegetables to grow betwixt them, or for the Beans to ſpread. As for the hoeing them after by the Hand or Dutch Hoe, or by the late Contrivance of running a ſmall Plow betwixt the Rows, as was before mentioned under the Head of Wheat; or, laſtly, for letting Sheep into the Beans in the Fields to eat the Weeds, which they will do at proper Times without prejudicing the Beans.

This Method of ſowing or planting the Beans, ſeems to have every Advantage that can be obtained both in reſpect of the Depth and Diſtance they are to be placed at; and alſo in regard to their being incloſed by mellow Soil, into which they may freely ſtrike every Way.

In Ground properly managed, the common Plow may be ordered to anſwer moſt of the Ends laſt mentioned, and is much uſed for thoſe Purpoſes; and, I preſume, the Method of ſowing by the Hand along with the Plow, as mentioned under the Head of Wheat, may be equally uſeful in the ordering the Beans. And the Gardeners are ſaid to love the Plow in this, as well as ſome other Caſes.

As to ſteeping of Beans it is not very commonly uſed for thoſe ſowed in the Fields, the Seaſon they are ſowed in being commonly wet, and conſequently there being no Occaſion for it, on Account of their being made to vegetate; but the Bean will bear ſteeping very well, and thoſe planted in Gardens late frequently are ſteeped with very good Succeſs.

I ſhall not here repeat what has been ſaid before, about Steeping in general, but refer the Reader to it, where he may inform himſelf of what is neceſſary is this Particular; and therefore ſhall only mention, that I have frequently ſteeped the Windſor and other Beans in Milk, in Milk and Water, in what is called mudgel-hole Water, or the Water coming from a Dung-hill; and in Water in which Sheeps Dung was diſſolved: in theſe ſeveral Liquids, varied different Ways, ſteeping for twelve, four and twenty Hours, and longer, and found they anſwered very well, I do not remember that any of them miſcarried, and theſe are Things eaſy to be met with, and what may be uſefully applied in almoſt any Quantity. I have not named the Kidney Bean above, for I apprehend that would be in the moſt Danger of ſuffering by ſteeping of any Sort.

The uſual Quantity of Seed for an Acre is about three Buſhels in the common Way, which is now found more than neceſſary; ſince Experience ſhews, that when they have more Room,

they

they bear much better both on Account of their having Opportunity to ſpread in a freer Air, and more Sun to refreſh them. And therefore both in the Drill Way of managing them, and according to the Advice of the Perſons beſt ſkilled in the Management of them, they ſhould not be ſet in Rows leſs than a Foot diſtant; and if wider the better, and not cloſer in the Rows than three Inches. The Farmer may eaſily proportion his Diſtances accordingly in any Manner of the planting them, as when the Ground is plowed for them, by miſſing one or two Furrows for their being any Way in Rows, gives him an Opportunity of hoeing and earthing them up: ſowing any Compoſt amongſt them, letting Sheep into them before they bloſſom, to top them if they run too much into Straw, or are infeſted with the pernicious Dolphin Fly, ſo frequently fatal to them; eſpecially when they grow cloſe, and in ſmall Incloſures. Againſt this the topping the Beans is very uſeful, and ſo it is in the making them to pod the better when kept down, and from running too much into Stalk. The Gardeners do this with Sheers, and they may be topt to about two Foot high, or to three in the Field, in the ſame Manner, with no great Pains, or with a Scythe, or a ſhort Scythe fixed in a proper Stick with leſs Labour.

It may not be amiſs to remind the Farmer to take Care frequently to change his Seed, which is very neceſſary to be done ſometimes, in all Sorts of Beans; and not to ſow Beans in the ſame Ground ſoon. The beſt Method of changing is, by bringing Seed from ſtiff Land to that which is lighter, and from the lighter to the ſtiffer.

The Seaſon uſual for the ſowing of Field Beans is, from the Middle of FEBRUARY to the End of MARCH: the ſtrongeſt and the wet Land ſhould be ſown the lateſt, and the other Sorts proportionably ſooner: ſome Regard is alſo to be had to the Weather.

Of the Soil; and preparing the Ground for Beans.

A ſtrong moiſt Soil ſuits the Bean the beſt, and it proſpers better in an open Expoſure than when confined in ſmall Incloſures; where it is moſt ſubject to Blights, and the pernicious Fly above mentioned; all agree that warm light Land is by no Means proper for Beans, though I have known ſome very good ones got on dry Lime-ſtone Ground, in ſmall Quantities in Gardens.

Here it may not be improper to remark, How the Nature of the Lime-ſtone Soil alters the Taſte of Beans, and other Vegetables; the greater Sweetneſs of ſandy Soils than of Lime others, has been frequently obſerved. But I do not remember that the Alteration produced by good Lime ſtone Ground, has been taken Notice of: which I can be more particular in, as I had Gardens both on dry Lime ſtone Ground, and on Clay Ground; the former of which produced much ſweeter Vegetables than the latter; tho' thoſe on the clayey good Land would frequently produce larger Vegetables, eſpecially Carrots and Parſnips: and as to Beans, there was ſo great a Difference, that my Beans growing on the Lime-ſtone Land, and thoſe in a neighbouring Village, which was all on the Lime-ſtone, were ſo ſweet, that the Water they were boiled in, had not that diſagreeable Smell and Taſte which common Garden Beans give, but was as ſweet as that Peaſe are uſually boiled in, and was uſed commonly by the Villagers to make Pottage of; and the Beans themſelves had a much ſweeter Taſte than thoſe growing on the clayey Soil. And it is well known, that Lime-ſtone Land is very dry by its Nature, and mine was on the Top of a Hill.

The Vales generally do beſt for the Peaſe, the Chiltern or Up-lands being frequently too light and dry for them; eſpecially if a dry Seaſon follow, or the Ground be plowed oftener than abſolutely neceſſary; by which it will be left hollow, or too light for them to ſtand, which is not the Caſe in the ſtiff Grounds. It will frequently admit ſeveral Plowings for them much to the Advantage of the Crop.

As to the preparing the Ground for Beans, there are two Things to be conſidered: When the Ground is only juſt broke up for them; and when, according to the Courſe of Tillage, it is to be prepared for, and ſet or ſowed with Beans.

In the firſt Caſe the Ground is ſuppoſed to be in a proper Condition for a good Crop, and then ſuch a Produce is expected. Alſo, that it ſhould be uſeful in making the Land mellow for an After-Crop of Corn; and likewiſe, to keep down the Weeds. We are told by a very ingenious modern Writer, That theſe Ends, and much the greateſt Produce will be obtained, if the Drill and Horſe Plow be uſed to ſtir the Ground betwixt the Rows of Beans.

How far the Horſe Plow will anſwer as to Weeds, has been ſhewn before. But the ſtrong Objection againſt it in this Caſe is, That it turns the Weeds toward the Beans, and that it is then more Trouble to get them out there, than the hoeing the whole with the Hand Hoe. I know an excellent Farmer who choſe laſt Year to lay out fifteen Shillings an Acre in hoeing his Beans by the Hand Hoe, as the beſt Way; not that he expected his Beans to pay him, but in order to prepare his Ground clean for a Crop of Wheat to follow; Beans being known not to impoveriſh the Ground, but rather to improve it for Wheat. Though it throws out great Productions, however, it mellows and lightens the Land for After Crops of Corn. but this Farmer was right where Ground is freſh, and ſome prepared Compoſt on it ſince broke up. The Land is commonly plowed early in Autumn, and they let it lie in Ridges till about CHRISTMASS, by which it has the Benefit of Winter Froſts and Weather: the Advantages of which have been before mentioned; after that it is then plowed in ſmaller Furrows. Two Plowings will make the Ground fine enough till it is plowed and ſowed, when the Furrows ſhould be made ſhallow.

The common Method of Plowing and Sowing being directed in a former Part of this Work, I ſhall not meddle farther in that Particular, nor repeat any Thing there mentioned.

In Caſe any Improvement is found proper to be added to them, during the Time of their Growth, almoſt any Compoſt may be ſpread amongſt them; and will preſently incorporate with the Soil, on the looſening it either by the Horſe Plow or Hand Hoe; but he muſt be a bad Farmer who has not his Ground in common good Heart for Beans.

Sir Hugh Plat mentions the ſowing two Buſhels of Salt amongſt the Beans, at ſeveral Times, and why may not ſome Sea Sand be ſowed amongſt them, or ſome Sea Water conveyed amongſt them; theſe are known to fertilize Ground prodigiouſly, and to be great Deſtroyers of Weeds and Vermin; and theſe are ſtill to be had without Duty, and in many Places may be ordered without any Expence, and with very little Trouble. In Cheshire I have known Brine poured on Pavements, to deſtroy Graſs and Weeds, which it will do effectually; and I ordered a Cart Load of the Sweepings of a Salt-work to be ſpread on a Parcel of very rough Ground, and it being laid thick on about two Hundred ſquare Yards, deſtroyed every Vegetable on it, Furze, Graſs, and ſo on, but would enrich the Ground for the future, and it would, by Degrees, become fruitful, as the Weather, Froſts, Rains, and Winds, and the penetrating Air alter the Salts in the ſame Manner as the Salt Marſhes, when encloſed from the Sea gradually diſcharge their over Quantity of Salts, and become improved into good Paſture Ground.

Small Trials of this Kind are eaſily made, with little Trouble, and at no Expence, and without the Hazard of any conſiderable Damage; and that the Reader may know the Proportion of Salt which there is in common Sea Water, a Gallon of Sea Water will produce about four Ounces: it being inconteſtably proved, by repeated Experiments (ſome of which I have made, and found true) that two Pounds of Sea Water, taken from the Surface, contains an Ounce at leaſt of Salt, or the thirty-ſecond Part of its Weight; and when the Water is taken from the Bottom it will produce ſome ſmall Matter more.

Common Salt weighs about fourteen Pounds to a Peck, the fourth Part of a Buſhel.

There are ſeveral other Things which might be mentioned as proper for the ſame Purpoſe, but ſome of them will undoubtedly occur to the Reader's own Obſervation, from what has paſſed; and others will fall into Conſideration under the Advantages of Beans, which we come next to treat of.

Of the Produce and Advantages of Beans.

A Reverend Author (excluſive of ſome Advantages ariſing from the new Huſbandry) reckons the common Produce of Beans to be about twenty Buſhels the Acre, which allowing three for the Seed is about ſeven for one; and adds, "That "no Grain yields a greater Increaſe than this, p. 103. "if it is rightly cultivated *, nor turns to "greater Profit to the Huſbandman." He then mentions one ſingle Horſe Bean producing ninety Pods or Kids, containing two Hundred and thirty-two Beans, which the next Year produced three Gallons; the next Year ſeven Buſhels and an half, the next Year ſeventeen Quarters and two Buſhels in four Years from one Bean.

But what is two Hundred and thirty-two Beans from one, in Compariſon of three or four Thouſand Grains produced from one ſingle Wheat and Barley Corn; of which certain Proofs have been before-mentioned; or what is the Produce of ſeven Buſhels of Beans for one; in Compariſon of above ten for one commonly had from Wheat; or twelve or more for one commonly had from Oats.

A very ingenious Writer mentions thirty Buſhels as a Produce of Beans not uncommon from good Vale Lands, per Acre; and that there may be an Increaſe of ten Buſhels the Acre more by the modern Huſbandry, if regularly purſued.

Now taking the Produce at thirty Buſhels as a Medium, which to be ſure is a full Allowance, and deducting the Seed there will be twenty-ſeven Buſhels clear, which, at two Shillings per Buſhel, will amount to two Pounds fourteen Shillings.

Out of which deducting Rent eight Shillings.

Three Plowings, twelve Shillings.

Harrowing, Hoeing, and Weeding, eight Shillings.

Reaping, Loading, and Threſhing, ſix Shillings, for the Straw is of no Value to ſpeak of; the whole of the Outgoings are one Pound twelve Shillings; which being deducted from two Pounds fourteen Shillings the whole Produce, there will remain clear, one Pound two Shillings.

But what is this, compared with the Profit of a middling Crop of Wheat, or ſuch a one of Oats; and yet, in this Eſtimate I have deducted nothing for any Manure which Beans may want, or occaſion the Want of to continue the Ground in a proper Courſe of Huſbandry.

But we ſhould not do Juſtice to this Species, ſhould we omit any other Advantages it is uſually attended with, or may be thought reaſonably capably of producing, either according to the old or new Huſbandry.

Beſides the Profit above-mentioned, it gives the Farmer an Opportunity of changing his Grain, and conſequently ſo far occaſioning the Production of better Crops of Wheat, Barley, Oats, and Clover, in their ſucceſſive Turns as was before-mentioned, and fully proved; it being undoubtedly true, that the longer any Grain is deferred before it is ſowed again on the ſame Ground, the better the Crop may reaſonably be expected to be.

Another Advantage of Beans is, that they give an Opportunity of planting or ſetting other Roots betwixt the Rows, which will not hinder the Growth of the Beans, and may bring in a conſiderable Profit; and whoever looks into a good Gardener's Ground, will ſoon ſee ſuch Varieties of this Kind, as to give him ſufficient Choice of this Sort. This the Gardeners call, under cropping, and great Variety of Vegetables, as Carrots, Turnips, Lettuce, and many more of the ſame Nature may be ſowed or ſet in the Interſtices.

Peaſe have frequently been ſown, and are thought

thought to do tolerably well with Beans, and it is ſaid may be advantageouſly ſupported by the Beans, but I apprehend that wherever they claſp round the Beans, there can be no Expectation of any Pods from the Beans as far as the Pea reaches; however, Peaſe may be ſafely ſowed betwixt them, when the Beans are ſet in Rows two Foot aſunder. Which Diſtance the beſt modern Writers allow as producing the beſt Crop, where there is tolerable Compaſs of Ground, which is the Caſe when Beans are ſowed in the Fields, which we are now upon.

Turnips ſowed betwixt the Beans would be found to anſwer very well, both as a Crop of Turnips, and for the keeping down the Weeds, which would be here a conſiderable Article.

When the Ground is hoed, or the Beans earthed up, the Turnips might be ſowed with very little Trouble or Expence, and the Mould would then be looſe for them to ſtrike in; and there would want nothing but a raking them, to cover them a little, and there can be no Doubt of their ſucceeding well.

Or if ſome Turnips were tranſplanted, and ſet at ten Inches or a Foot diſtance betwixt the Rows, this Work would be readily done, and undoubtedly produce very large Heads, as I have frequently experienced in often removing Turnips; which is alſo done when they are tranſplanted for Seed, and I ſhould not doubt their producing good Turnips too, and large enough for all uſeful Purpoſes; though ſuch a tranſplanting muſt be thought to give a Check to their Growth, but that may be allowed for in the Time appropriated to them.

The Drill Method of ſowing is thought not to ſuit Beans very well, both on Account of their Shape, which is an Obſtacle to their falling regularly in the Rows; and they requiring a ſtiff Land, and being frequently ſowed in the rich Vale Land, this Method of Huſbandry does not well ſuit that Sort of Ground, as one of the warmeſt Writers for the Drill Method of Huſbandry confeſſes.

Of reaping Beans.

Beans are uſually reaped with Hooks, after the ſame Manner Peaſe are, or ſhorn after the Manner of white Corn; and in both Ways after bound up in Sheaves, and ſet on an End together, as Wheat is in the South.

They are commonly bound with Straw Bands, but the better Farmers buy a coarſe Sort of Hemp Twine by the Hundred Weight at a ſmall Expence, and cutting them into proper Lengths, bind up the Bean Sheaves with them; and this makes every thing after eaſy and commodious in the Management of them; and by allowing about three Inches more than neceſſary the firſt Year, for the Loſs of cutting them open when laid on the Floor for threſhing, they will ſerve two Years very well.

Beans are frequently malted, and mixed with other Malt for brewing of Ale, and anſwer to ſeveral very good Purpoſes.

Of keeping Beans.

Beans will keep in Sacks in a common Chamber very well, for a conſiderable Time, or in a Stack in their Straw if dry when placed there, and kept dry. And ſome keep them in Hair Bags, to ſecure them againſt Vermin.

There is an odd Cuſtom in Essex, of putting four Buſhels in a Sack, and at Hempsted Market, not far from St. Alban's, ſo famous for Wheat, is a worſe, for they put five Buſhels of Wheat in a Sack, which is above three Hundred Weight.

In the midland Counties they only put two Buſhels into a Sack, and two ſuch Sacks on an Horſe for a Load to the Market, which Sacks are readily and eaſily carried about; and anſwer every uſeful End the above Methods of theſe Southern Counties can be thought to do.

But to facilitate the Removal of theſe Sacks in their Granaries, and other Places, they have a ſmall Machine in Essex, and I ſuppoſe in other Places, which does it with great Eaſe; and as it is very convenient, and may be greatly improved, and coſts but one Shilling and Eight-pence, or two Shillings, the making, I ſhall here give the Deſcription of it.

A Machine to wheel Sacks of Corn, in Granaries, Corn Chambers, &c.

It goes on two wooden Wheels, the Diameter of which is five Inches, pegged on the Outſide with wooden Pegs through the End of the Axle-tree, which is eighteen Inches long, and where ſquare an Inch and an half, and faſtened in the Stilts, which are there a Foot aſunder, and the other is round for the Wheels to run on.

The two Stilts which guide it, are like thoſe of a common Plow, are three Foot ſix Inches long, and kept aſunder and firm by a Slat let through them at two Foot high, where the Stilts are better than fourteen Inches wide betwixt them, and two Inches and an half on the Side, and an Inch and an half Front, and grow narrower in the Subſtance, but wider betwixt them to about ſeven Inches, and then are rounded and bend backward to handle them by.

At the Bottom a Board four Inches and an half broad, and an Inch and half thick, is let a little into the Axle-tree and Stilts, and ſloped downward; and the under out Edge of the Board is taken a little off, ſo that it falls near level with the Bottom of the Wheels, and the Machine ſtands upright when ſet on the Level, but is bent backward by the Handle when the Sack is on it, and the Sack will reſt on it as it ſtands.

An Iron Plate an Inch and an half broad, is nailed ſix Inches on the Bottom of each Stilt, and along the Axle-tree, and two Inches over the bottom Board, to ſtrengthen it.

Croſs the Outſide of the bottom Board a Rib is nailed, an Inch and an half at each End, even ſo far, but the Middle riſes gradually each Way to a thin Edge, which, on bending the Stilts forward, goes under the Bottom of the Bag, and when the Top is pulled on it to the Stilts, and this keeps the Sack from ſlipping off.

The Subſtance of the Weight reſts on the Wheels, and is eaſily turned any Way by the Stilts or Hands.

Moſt People know the Weight a Perſon may draw or wheel with Eaſe, in Compariſon of what they can carry; and the common Wag-

goners

goners draw three Ton with five Horſes, when twelve Hundred would be a ſufficient Load for them.

And why may not a Board be fixed to it at the croſs Bar, and be opened when wanted, and ſet on the Foot Board by an Iron, to drop down and hold it, as is often done in Seats; on which almoſt any Thing might be carried from Place to Place, or the Wheels might be made deeper, if thought neceſſary, or a Pair of larger Wheels occaſionally be eaſily put on the ſame Axle-tree.

To theſe Articles we ſhall add four more of the Pulſe Kind, Peaſe, Tares, Chiches and Lentils; and thence we ſhall be led according to the Courſe marked out in our Plan, to the Graſſes.

CHAP. I.

Of Peaſe.

THE Pea appears to us at preſent under ſo many Forms, that there is need to explain them ſeparately; diſtinguiſhing which properly belong to the Farmer, and which ſolely to the Garden. About great Towns, particularly LONDON, the Farmer ſows ſome Kinds of the Garden Pea, and the Gardener makes his Plantation in the Fields, ſo that they intrench upon one anothers Province. There are therefore ſome Kinds of Peaſe to be conſidered as being brought into Uſe in common between them; others that are peculiar to the Farmer; and another Claſs, that the Gardener is alone concerned withal. Of the two former we ſhall treat in this Place; with the third, the Farmer haveing no Concern, we ſhall not meddle.

It will be firſt proper to ſhew the Huſbandman what the Pea is; what are its really diſtinct Kinds, and what its Varieties: for theſe laſt are by much the moſt numerous, and are called by peculiar Names, as if diſtinct in their Nature like the others. The Art and Induſtry of Gardeners will vary theſe for ever, but the ſtrict Obſerver will conſider them as accidental, not real Changes.

The Pea is a climbing weak Plant, with long ſlender Branches, and numerous Leaves, furniſhed with Claſpers or Tendrills, by means of which it lays hold of whatever ſtands near for its Support. The Flowers are of that Kind, Writers call Papilionaceous, from their reſembling in Form a Butterfly, in Latin Papilio; and they are ſucceeded by Pods, in which are contained the Peas, which are naturally round; but vary in Size and Colour according to the Species, or the accidental Variation made by Culture.

The Flower of the Pea ſtands in a little green Cup, formed of one Leaf, divided into five Parts, the two upper of which are larger or broader than the others.

The Flower itſelf is compoſed of four Leaves, in the Manner of the others of that Kind. One ſtands upright and is very broad, two ſtand ſideways, and are ſhort and roundiſh. The former Botaniſts call the Vexillum, theſe two the Alæ; the fourth Leaf ſtands at the Bottom, and is ſhort and compreſſed, this is what they call the Carina.

Within this Flower ſtand ten Filaments, nine of theſe are ſhort, and grow together; and one is longer, and ſtands ſeparate. This Diſtribution of the Filaments gives Origin to one of the new Claſſes in Botany, called Diadelphia. All theſe Filaments have roundiſh Buttons on their Tops.

Among them riſes the Rudiment of the Fruit or Pod: this, while the Flower laſts, is very ſmall and flatted; and there riſes from it a membraneous Thread, to the Side of which, near the Top, there grows a little Head pierced for the Reception of the Duſt, from the round Heads of the Filaments.

This Duſt impregnates the Seeds, and when the Flower is fallen they ſwell, and the Rudiment grows with them, forming the Pod and Peaſe. We ſhall hereafter mention thoſe Varieties of the Pea riſing from Culture; but are here to take Notice that there are four Species, which, from their general Form and Manner of growing, are plainly and really diſtinct Kinds, owing to Nature, not to Art, or the Accidents of Culture: theſe are,

1. The Garden Pea, which may be called the white Pea, or the manured Pea in general. This is the Origin of the ſeveral Varieties hereafter to be named.
2. The Field Pea.
3. The Sea Pea.
4. The ſimple leaved Pea, or Ervilia.

The firſt, or Garden Pea, is known by haveing winged Leaves, and ſeveral Flowers upon one Foot-ſtalk. The ſecond, or Field Pea, has but one Flower upon each Foot-ſtalk. The third, or Sea Pea, has an angular Stem, and ſeveral Flowers upon each Foot-ſtalk. And the fourth differs from all the others, in that it has ſimple or ſingle Leaves.

What are called winged Leaves, are compoſed each of ſeveral Pairs of others; but this has them ſingle. The firſt of theſe is the Pea we commonly cultivate in Gardens, the ſecond is that ſown in Fields in moſt Places in the Country: and under each of theſe really diſtinct Species, there are many leſſer Varieties: the third, or Sea Pea, is wild in ENGLAND, it grows on the Sea Coaſts, in barren naked Cliffs of Rocks, and among Pebbles where no Earth is ſeen to give it Nouriſhment. The fourth is a Native of the Greek Iſlands, and of ſeveral Parts of EUROPE.

It is a memorable Circumſtance, that in a Time of great Scarcity of Proviſion, the People about our Coaſt found the Sea Pea in great Plenty, and fed upon it. Till Neceſſity had ſent them to its Stores, they never had obſerved it, and they then thought it ſent by Miracle to their Relief.

The Reaſon of its growing and thriving where no Earth appears is, that it ſends the Roots to a great Depth, and then finds it. The Produce of it is very great in its wild State, as appears by the Numbers who were in that calamitous Time ſupported by it; and there are Reaſons enough to try how it would anſwer by Culture.

There

There are many Acres of naked and waſte Sea Beach in this Kingdom, on which nothing uſeful grows at preſent; it would therefore be highly worth while to try what would be the Effect of ſowing this Native Sea Pea upon them.

We ſee it will ſerve for Food to ourſelves, but if only for Cattle, it would ſtill be worth raiſing.

CHAP. II.

Of the Varieties of the Garden Pea, called the ſeveral Kinds of Garden Peaſe.

WE have ſhewn what the Pea is, and what are the really diſtinct Kinds of it: we are now to lead the Huſbandman into the Wilds of Art, and enter upon the Kinds made from the firſt by Culture. This is a Store almoſt inexhauſtible, and is every Day increaſing. We know how the Floriſts raiſe a Variety of Auriculas, Tulips, and Carnations from a few Original Kinds, and ſo it is in the Peaſe. Good Ground, and careful Management, go a great Way; and the Mixture of the Duſt from the Buttons on the Threads in one Species with that of another, and its going in this Mixture, or ſingly, to impregnate the Seed does the reſt.

One Way or other a great Change is made, and the Table is ſupplied with an excellent Variety at different Seaſons.

If we were writing to inſtruct the Gardener, we ſhould enter at large upon this Head: but as the Huſbandman has leſs Concern with it, we ſhall treat it the more lightly; not omiting it however, as he may in particular Situations find it profitable to fall into the Practice, nor neglecting any uſeful Caution. The three moſt diſtinct Varieties, are, firſt, The great or Rouncival Pea, diſtinguiſhed by its Size. Secondly, The ſquare Pea, diſtinguiſhed by its Shape; and, thirdly, The umbellated Pea, diſtinguiſhed by its Manner of growing, which is in round Cluſters, reſembling an Umbrella. Theſe the Curious look on as the moſt remarkable Varieties of the Pea, but the Gardeners enter into a longer Detail.

Their principal Kinds are, 1. The early Pea, called the Hotſpur, and which Foreigners call the early Engliſh, our Gardeners having firſt brought it up.

2. The Dwarf Pea. This is a low Kind, but the Stalk is much firmer and ſtronger than the common one, wherefore it ſucceeds much better in many Kinds of Soil.

3. The French Dwarf Pea. This is leſs ſturdy than our own, but the Pea is more delicate.

4. The ſoft ſhelled Pea. This has a Huſk ſo tender and ſweet, that it is eaten in the Manner of the French Bean.

5. The large Pea, called the maple Rouncival. This has a beautiful red Flower, and the Pea, when ripe, is variegated with ſeveral Colours. This is ſometimes ſown in Fields.

6. The Crown Pea. This is the ſame with the umbellated Pea before named, but the Gardeners commonly raiſe a ſmaller Kind than that deſcribed by Authors.

7. The Spaniſh Marotto Pea. This is of the Rouncival Kind, very large, when full grown, and diſtinguiſhed in the dry Seed by a black Line.

8. The Marrowfat. This is diſtinguiſhed by the Breadth of the Pod, and the Softneſs and Sweetneſs of the Pea; and is the ſame we uſed to call the Dutch Pea, and the Admiral Pea.

9. The Union Pea. This is one of the Rouncivals, well taſted, but very large.

10. The flat Rouncival. This laſt is a great Rarity in ſome of our curious Gardens, and is a Kind of middle Pea between the Rouncival or Marrowfat.

Theſe are the moſt certain and diſtinct Kinds, as they are called; we have already told the Huſbandman they are only Varieties; and, on Enquiry among the Seedſmen, he will have his Choice of many more.

The four principal he ſhould meddle with, if he do with any, are the common White, the Hotſpur, the Rouncival, and the Marrowfat; and as it may ſometimes be his Intereſt to cultivate one or other of theſe, we ſhall lay before him in general Terms, the Methods found moſt ſucceſsful in this Way.

CHAP. III.

Of the Culture of the Garden Peaſe.

EARLY Peaſe are frequently raiſed about London, by the Aſſiſtance of Walls and hot Beds. This is done thus. They are to be ſown under a warm Wall, or Pales, in October. The Earth is to be drawn up about the Plants as they riſe in Height, during the Winter, for by this Means they will be ſecured againſt the Froſts; and having been thus kept alive till the Beginning of February, they are then to be removed to hot Beds made for that Purpoſe, covered with fine Mould, and ſheltered by Frames.

If the Winter be very ſevere, they muſt be covered lightly while growing in the natural Earth; and when taken to the hot Beds, they muſt be planted at two Inches Diſtance, in Rows a Foot aſunder. They will thus flower and produce their Fruit at ſuch a Seaſon, as will make it bear a great Price.

The French Dwarf is a very good Kind for this Purpoſe; but this being a Piece of abſolute Gardening, we ſhall not here enlarge upon it farther.

Theſe forced Peaſe come earlieſt in Seaſon; the next are the Hotſpurs. With the former we cannot adviſe the Farmer, in general, to have any Thing to do, nor much with theſe, for they will take off his Attention from more important Things; if he have Plenty of ſpare Dung, and a Taſte for theſe Matters, he may employ a proper Servant, and it may anſwer: but he muſt not regard them too much himſelf.

The Hotſpur muſt be ſown in a rich Mould, and warm Spot, in the End of October; and the Farmer who will meddle in theſe Things muſt obſerve, that as the Gardeners make Varieties upon Varieties in this Article, that called the Maſter's Hotſpur is the earlieſt and beſt.

He muſt get his Seed from ſome honeſt Perſon; and he muſt buy every Year; for if he ſow that of his own Produce, it will degenerate.

As theſe riſe in Height, the Earth muſt be drawn up about their Stems with a Hoe in dry Weather; and if the Froſts are ſevere, ſome old Pea Stalks, or other light Covering, muſt be thrown over them, and taken off when the Seaſon is milder.

Being thus kept alive till Spring, they muſt then be carefully weeded, and kept clear of Slugs. If there be many of them in the Ground, a little Lime carefully ſpread will deſtroy them, and rather forward than hurt the Plants. Thus managed, the Peaſe will bring an early, and large Crop. The Spaniſh Morotto, which is properly a Rouncival, as we have ſaid before, is to be ſown in FEBRUARY; and in the Beginning of MARCH the common Rouncival.

After this there ſhould be a freſh Crop of one Kind or other ſown once in a Fortnight during the Seaſon, and they will in this Manner ripen one after another, and the Owner will be able to ſupply the Market at all Times.

All the Care they require is, to keep them clear of Weeds, and to be cautious not to tear and deſtroy the Stem in gathering.

According to their Size they muſt be ſown at different Diſtances: the largeſt Peaſe the fartheſt aſunder.

We have in this ſuccinct Manner given the Management of the Garden Pea, becauſe not properly the Buſineſs of the Farmer: we ſhall now proceed to what is truly and perfectly ſo, that is, To the Management of the Field Pea, which is a very proper, and important Article.

CHAP. IV.

Of Field Peaſe.

THE Field Pea, like the Garden, is divided into many Kinds, the principal of which we ſhall mention; and aſſiſt the Farmer to underſtand their Nature, and to take the beſt Methods for their Cultivation. Theſe Kinds are,

1. The white Pea. This comes the neareſt to the Nature of the common white Pea of the Garden of any; and its principal Difference is, that it is ſmaller and leſs delicate.

2. The Grey Pea. This is a large and very uſeful Kind.

3. The blue Field Pea, called in many Places the Hog and the Pig Pea, though the grey might as well have been called ſo.

The Huſbandman will find a Multitude of Varieties of each of theſe branched out in the ſame Manner as thoſe of the Garden Kind, and named from the Places where they have been raiſed, and other trivial Accidents; but we ſhall cut off a great deal of Confuſion and Perplexity on that Head, by telling him, That all that vaſt Variety are to be reduced to theſe three principal Kinds; and that theſe being very diſtinct in themſelves, and very ſtrongly marked by their different Colour, he will always find it eaſy to diſtinguiſh the three ſeverally from each other, and know to which Kind he is to refer any of the reſt.

The white, the grey, and blue Pea, are perfectly diſtinct, and require a ſeparate and various Management; but then that which is proper for one white Pea is proper for all white ones, and ſo of the others.

The white requires one Kind of Soil, the grey another, and the blue ſucceeds beſt in a third. This is a very material Conſideration, which we ſhall explain in the ſucceeding Chapter, in the Regard of the others. As it is with Reſpect of Management, ſo it is with Soil, all white Peaſe require the ſame Soil with the common white; all greys the ſame with the common grey; and all blue the ſame with the common blue. This being a Certainty, the whole Trouble of ſtudying thoſe ſeparate Species may be ſpared to the Huſbandman; for, in knowing how to manage theſe three, he knows all that can be required for the raiſing of them all, and need not perplex himſelf with uſeleſs Diſtinctions.

CHAP. V.

Of the proper Soils for the three Kinds of Field Peaſe.

EACH of the Field Peaſe ſucceeding beſt upon its peculiar and proper Soil, it muſt be the Huſbandman's firſt Buſineſs to eſtabliſh that Knowledge thoroughly in his Memory: for on that will depend his Succeſs. Peaſe are very profitable, and a very uſeful Crop on many Occaſions: when he is about to raiſe them, let him firſt examine the Nature of his Land, and then ſuit the Kind to it; for he may in the ſame Field be in a Manner ſure of a large Crop of one Kind, whereas he muſt as certainly have a poor one of another.

It is a very ſingular Thing that there ſhould be ſo much Difference in the Kinds of the ſame Plant, with Reſpect to the Soil they require; but Experience eſtabliſhes that Doctrine; and when Experience is certain, and proved by frequent Repetitions, he is a very weak Man who goes againſt it.

The white Pea being moſt of the Nature of the Garden Kind, ſucceeds beſt upon that Land which is moſt like Garden Ground; therefore let this Kind be ſown in a Field, the Soil of which is fine and rich. A deep mellow Earth, or a rich Loam that is not too ſandy, are the two Kinds of Soil that ſuit beſt with this Species.

The grey Pea is hardy, and loves Moiſture; for this Reaſon a clayey Soil ſuits beſt with it.

The blue Pea is hardy like the grey, but nothing hurts it more than cold and moiſture, therefore its proper Soil is the light, ſandy and dry.

Theſe are the Diſtinctions of Soil for the three Kinds of Field Peaſe, and as we have before obſerved, the Huſbandman needs not trouble himſelf about a Multiplicity of Names, but examine them according to their Colours, and perplex himſelf no farther.

All white Peaſe, of whatever particular Name, love a mellow Earth; all grey Peaſe, a clayey; and all blue Peaſe, a ſandy Soil: this is the general Direction. As there are certain Soils that ſuit them particularly, ſo there are alſo ſeveral diſtinct Kinds of Manures, which beſt agree with them, according to their ſeveral Natures.

In general, Dung is the Manure that beſt agrees with the white Pea; and nothing enriches the Ground for the blue Pea like Lime. As we have mentioned a clayey Soil for the grey Pea, ſome may be ſurprized at our naming Marle as the Manure in which it moſt delights; but we have ſhewn in treating of Manures, that the proverbial Saying there is againſt marling of Clay, is not ſo univerſally true as has been imagined.

Any Soil in which there is Clay, will ſupport the grey Pea profitably; and Marle will be found a Manure that will enrich it excellently for this Purpoſe, at the ſame Time that the Pea itſelf improves it for Corn.

This is an Article of great Conſideration. The Pea not only yields a good Crop in itſelf, when ſown upon its proper and peculiar Soil; but it ſerves the Huſbandman in other Lights. It is always a Method of deſtroying Weeds; it improves the Land on which it has grown, and excellently prepares it for other Crops.

The Article of the particular Soil ſuited to each Kind of Pea, has not been hitherto ſufficiently conſidered; and for that Reaſon the Farmer in general is not acquainted with the great Advantage of this Pulſe.

He finds it ſerve in the Succeſſion of his various Crops, and when Chance directs him to ſow the right Pea upon the right Soil, he ſees the Advantage in its full Light. Theſe are called favourable Years, and the Expectation of them keeps up his Spirits; but what he attributes to ſome unknown Cauſe, may be the Effect of his own Care and Application; and what he thus finds from Chance now and then he may at all Times command from proper Management.

The grey Pea will yield its full Produce in thoſe ſtiff Soils, which ſo well agree with its Nature, without the frequent Fallowings, ſerveing in the Place of a Fallow, while it is yielding all the Time ſo profitable a Crop; and ſo it is in each of the others, only obſerving this proper Management.

In Reſpect of Manures, Peaſe will always anſwer in ſome Meaſure to the Expence of them; and it is to be conſidered, the Profit is not to be expected wholly from theſe, for they exhauſt the Land ſo little, it is not the leſs fit for a ſucceeding Crop.

The general Obſervation is, that Peaſe ripen earlier in Land that is leſs manured; but the richer it is made, the greater is their Produce.

Wheat, the richeſt and moſt profitable of all Grain, follows Peaſe excellently; and the Seaſon of ſowing the Wheat comes ſo naturally after that of gathering the Peaſe, that it ſeems as if they were deſigned to come after one another.

As ſoon as the Peaſe are cut, the Land ſhould be plowed acroſs; after this it ſhould be harrowed, and then plowing it again in the Beginning of October the Wheat is to be ſown.

CHAP. VI.

Of the ſowing of Peaſe.

TWO Articles are to be conſidered under this Head; the Quantity of Seed Peaſe proportioned to the Ground, and the Manner of placing them in it.

The Reader will remember what we have ſaid with Reſpect to the Garden Peaſe; namely, that the larger the Sort, the greater ſhould be the Diſtance of the Plants. The ſame holds good in the Field Kinds: and upon this depends the firſt Article of their Management.

Good Ground will enlarge a poor Pea, and a ſtarving Soil will reduce one that is naturally large in its Size; but we can here ſpeak with ſufficient Certainty, knowing what is the Condition of the three Sorts into which we have divided Field Peaſe in Ground equally favourable.

The Farmer is then to know that the grey Pea is naturally the largeſt Plant, the white the next in Size, and the blue the leaſt.

We have obſerved that a good Soil will enlarge the ſmaller Kinds, perhaps ſo as to equal theſe naturally larger, on a poor one; but there is alſo a Difference in the Size of the Plants among theſe different Varieties we have named, of theſe ſeveral general Species. All this is to be conſidered as the poſſible Occaſion of accidental Variations; but, in general, the Rule is what we have here laid down; and, conſequently, the greateſt Number of Peaſe is to be allowed to the Acre in the blue, and the leaſt in the grey Kinds; the white being kept as a Medium.

We ſay Number in this Place, becauſe the Meaſures may deceive; the grey Pea being larger, conſequently fewer fill the Buſhel. This makes a certain Difference, but not ſo much as is neceſſary in the Management of the Plants as to Diſtance in the Field. The Farmers know this, and proportion their Meaſures accordingly; but though they are right in the Thing itſelf, they fail in the Degree, for they allow too large a Proportion of the great Kind.

The Allowance in the common Way of Huſbandry, in thoſe Counties where the Culture of Peaſe is beſt underſtood, is two Buſhels of the grey to an Acre: they allow three Buſhels to an Acre in the white Peaſe, and four in the blue. But all this is too large an Allowance; nothing ſucceeds ſo ill in a promiſcuous and irregular Sowing as Peaſe, and when they are planted regularly, there may be an abſolute Certainty as to the Quantity and Diſtance. The Time of ſowing Peaſe differs alſo according to the Kinds; though this rather reſpects the Soil to which they are ſuited, than any Thing in the Pea itſelf.

The grey Pea is to be ſown in February, becauſe growing in a cold ſtiff Soil, it makes at firſt but a poor Progreſs. The Time for the white Pea is the Beginning of April; and the blue may be ſown a Fortnight later than this:

this: the Middle of April is the beſt general Time.

The Huſbandman who recollects what we have ſaid on the Nature of Soils in our firſt Book, will eaſily conceive what we mean by this: we have ſaid that ſandy Soils make a quick Shoot in whatever is ſown upon them, and therefore this late Time is very proper, for they have ſtill enough of the Seaſon for their Growth. The white Pea has a Soil of a middle Nature between theſe, and therefore it is to be ſown at a middle Time.

We now come to the Manner of ſowing them; and as a great deal depends on this in the common Way, and more may in a better Practice, we ſhall conſider it at large.

The common white Pea is uſually ſown with a Broadcaſt, and harrowed in. This is that promiſcuous and uncertain Method we have before mentioned, as ſo improper for Peaſe of any Kind.

The uſual Method is to ſow the grey Pea under a Furrow; and this is ſo hardy a Kind, that it may be put into the Ground any Time during the latter Part of the Winter.

The blue Pea is ſown as the white, only thicker, and is harrowed in after the ſame Manner.

This is the common Way in many Places, but it is the worſt of all. The firſt Improvement for the Planting of Peaſe was the Suffolk Dibble, ſo called from its Place of Invention or firſt Uſe. This is a Kind of Iron Rake with the Tines ſet parallel to the Handle. The Handle is of the ſame Form as in the common Garden Rake, the croſs Piece is thicker, and there are four, five, or ſix large Iron Spikes let through it. The Way of uſing it is this, a Man goes over the Field with the Dibble, and Women follow him with Peaſe in their Aprons. He ſtrikes it into the Ground, preſſing down the Tines with his Foot upon the Back of the croſs Piece. Thus four, five, or more Holes are made, into which the Women drop their Peaſe, one into each Hole, and leave them open. This done, the whole Field is lightly harrowed over, and all are covered together.

The Perſon who ſtrikes the Dibble, generally goes over the Field backward and forward in Rows, or Lines, a Foot aſunder, but 'tis done at random, and the Peaſe grow in a ſlovenly and irregular Manner.

This Method is very expeditious, and diſpoſes the Peaſe with a Degree of Regularity; it is therefore, according to the common Practice, greatly preferable to the random Method of ſowing them by Hand; but it is capable of eaſy and great Improvement.

In the firſt Place the Farmer who intends to ſet his Peaſe by the Dibble, ſhould have three Kinds of them made according to the Difference of his Peaſe, and the Diſtance they require in growing. He ſhould have one for grey Peaſe with the Tines five Inches diſtant, another for white with them at four, and another for blue at three Inches Diſtance. The Tines ſhould be longer for the grey than for the others, and ſhorteſt of all for the blue; becauſe Experience ſhews, That the Seed of the grey will bear deeper Covering in the Ground; and this is an eſſential Article; the Seeds of no Crop whatever being more in Danger from Mice, Birds, and Vermin.

When the Farmer has thus provided himſelf with proper Inſtruments for his ſeveral Species, I would have him order the Dibbler to go over the Ground with Regularity, drawing a Gardener's Line acroſs it for that Purpoſe, and working cloſe to it. This would ſet the Rows exactly ſtrait, and would make the work eaſier and leſs hazardous to the Hoers.

The ſeveral Rows might thus be eaſily planted at an exactly proper Diſtance, and that proportioned to the Kind in each. Thus for the common Huſbandry the grey Pea Rows ſhould be two Foot aſunder; the white a Foot and half, and the blue little more than a Foot.

Thus would the Field be planted with perfect Regularity, and the Hoeing and Reaping would be done the more eaſily. There would be a little more Expence, but very little in the firſt Operation; but this would be ſaved in the two others.

We have named here what may be called a middle Diſtance for the ſeveral Species, a finer or coarſer Soil, a richer or poorer Ground make ſome Difference in what is to be done in this Reſpect. The Farmer having here the Medium, will eaſily make the proper Variations.

In ſome Places they follow the Garden Practice in the Field, opening Trenches by Line, and covering the Peaſe, when in the Ground, with Hoes. This is better than the Method by the Dibble, in that it leaves the Earth more looſe all about them, but it is more expenſive, and the other ſucceeds very well.

Having named what are the ſeveral Manners of ſowing or ſetting of Peaſe in the Practice of the common Huſbandry, it is Time to ſpeak of what may be done in this Article by the Drill Plow, and the Horſe Hoe, its happy and proper Attendant.

We have ſhewn how vaſtly many other Crops are capable of being improved by this Practice, but there is none that can be ſo greatly aſſiſted by it as the Pea of every Field Kind; nor any to which it is ſo happily ſuited.

We have ſhewn the Advantage there is in ſetting the Peaſe in Rows by the Dibble, and mentioned wherein the Garden Method of the Trench and Hoe is ſuperior to this; but the Drill Plow anſwers both Purpoſes together; it does better than either by many Degrees, and the Expence is greatly leſs.

We ſhall adviſe the Farmer to uſe this Method preferably to any other, and ſhall give him all the needful Directions for it in a very few Words. Having explained at large in a preceeding Book the general Method of Drilling, and the Structure of its Inſtruments, a very little is needful to be ſaid in ſuiting it to the particular Circumſtances of any Crop.

Let the Farmer ſee his Inſtrument be properly made, and let him go over the Field ſowing his Peaſe in double Rows, with a Foot Partition, and with four Foot Interval between every two Pair of Rows.

The

The Peaſe will thus be let in regularly: the Earth will lie looſe about them, they will ſhoot freely, and they will be diſpoſed in the moſt happy Manner that is poſſible for Weeding and Reaping.

CHAP. VII.

Of weeding the Pea Field.

AS we have laid down the ſeveral Methods of ſowing Peaſe, we muſt give Directions for the weeding them accordingly, each Manner of ſowing requiring its peculiar Manner of weeding. The general Deſign however being the ſame in all theſe Operations, the Methods ſeverally neceſſary will be laid down in few Words.

When Peaſe are ſown in the random Way, the Hoers are to be ſent into the Field when the Crop is up, and to have Orders not only to cut up the Weeds, but to thin the Peaſe where they ſtand too thick, which they always do in ſome Places, however careful the Hand may have been that ſowed them.

Peaſe are round and ſmooth, therefore they will, from their Shape and Surface, roll about eaſier than any other Kind of Seed. We have ſhewn before how apt Corn is, when ſown in the common Way, to run in Heaps in the Holes, and leave other Parts of the Field deſtitute; but this is much more the Caſe in the Peaſe, becauſe of their Figure, and hence it is that of all Seeds ſown promiſcuouſly they are the moſt apt to riſe in Cluſters. The hoeing them thinner in theſe Places is alſo the more needful, becauſe in no Caſe the Plants more hurt or impoveriſh one another.

For theſe Reaſons the Farmer muſt be careful in his Inſtructions; and muſt keep his Eye now and then upon the People, otherwiſe he will have a much poorer Crop than he need.

When the Peaſe are ſet by the Dibble, made according to our Directions, the Hoer's Buſineſs is reduced to the one Point of cutting up the Weeds: and it is by much the more eaſily done, becauſe he is to work in regular Spaces.

In the other Way, by the Trench Hoe there will be the ſame Advantage of a clear Space to work in; but as the Seeds have been there ſcattered a little at Random, the Hoers muſt be ordered alſo to thin them in the Rows where they meet with Spaces, in which they ſtand too thick.

Theſe are the Methods in the ſeveral common Ways of planting this Pulſe, and the Advantage of the Hoeing is not confined to the preſent Crop; for deſtroying the Weeds, it prepares the Land excellently for that which is to follow.

In the Method we have propoſed of ſowing by the Drill, the Horſe Hoe, as well as the Hand Hoe, is to be employed; and the Effect of this upon the preſent Crop is prodigious, while at the ſame Time it acts as a thorough Fallowing of the Land for that which is to come afterwards.

We have ſhewn to what a Depth the Root of the Sea Pea will penetrate the Earth for Nouriſhment, all Peaſe are enclined to the ſame Particularity; and as few Plants with fibrous Roots penetrate deeper, none whatever ſpreads farther under the Surface at the ſame Time.

This may ſhew as the Reaſon of what we ſee in Practice ſo certainly, that there is no Crop which receives ſuch great, palpable and evident Advantages from Horſehoing.

We ſee how deep the Earth may be moved advantageouſly for Peaſe, and there is no Way of doing this but by that excellent Implement the Hoe Plow; and as the Advantage, in this Reſpect, is much leſs from Handhoeing, which only juſt breaks the Surface, ſo it is in Reſpect of the improving the Ground for future Crops.

When the Drill Plow has been employed in ſetting the Peaſe in double Rows, and in the large Intervals, as we have directed, the Horſe Hoe muſt come in to clear thoſe Intervals and nouriſh the Crop, and fallow the Ground; while at the ſame Time the Hand Hoe is neceſſary among the Plants. This however need be uſed but once, the other muſt be repeated occaſionally, and the Manner of uſing both is this.

When the Peaſe are about four Inches high, the Hand Hoers are to be ſent in, but as they have only a very ſmall Part of the Ground to work upon, a few of them will do for a large Field; and a little Time will be ſufficient.

When the Peaſe are at the Growth juſt named, they will ſtand according to this Method of ſowing, in double Rows, with a ſmall Space between Row and Row, and a great Interval between one Pair of Rows and another. The whole Ground between and about them, will be well cover'd with a young Crop of Weeds, for this is a Time at which they ſhoot in Abundance, and grow quick.

The Partitions or ſmall Spaces between one Row and another, in each Pair, are the only Part where the Hand Hoers are to be employed; the larger Intervals are to be left for the Horſe Hoe, which is to be brought in afterwards.

In this Handhoeing theſe Spaces muſt be perfectly cleared of Weeds, and that being once done, is not to be repeated: for the young Crop being thus once got down, will never be ſucceeded by another in that Place. The Rows at this Time appear diſtinct in the Fields; and there is Room for the Growth of Weeds between one of them and another, but ſoon after this the Peaſe grow to a Height, and meet one another, ſo that no Weed can grow between them.

This Handhoeing being over, the Ground is to be left to itſelf ſome time. The moving and breaking the Earth juſt about the Roots of the young Crop, on one Side, will do them great Service, as they now are young, and ſpread principally at a very little Depth: afterwards they will require a Supply at their greater Depth, and that will be given them by the Horſe Hoe, though it could not by any other Means whatever. This is what they extreamly want, and this is the Reaſon of that vaſt Fertility which will follow the Uſe of the proper Inſtrument to give it to them.

When the Weeds in the Intervals are grown to ſome Height, the Horſe Hoe is to be ſent into the Field: it muſt be carried ſtrait up in the

Midſt of every Interval; and it muſt be ſet to cut deep.

This will tear up the greater Part of the Weeds, and bury the reſt, and will not ſhake the Plants by coming too near them, that being an Accident which, till they acquire more Strength, might greatly hurt them.

If the Farmer be very curious, he may now ſend in his Hand-Hoers again, with Orders to cut up the Weeds cloſe on the Outſide of every Row, as before they did cloſe on the Inſide. They are not now to go over their former Work again: that was confined to the Partitions between one Row and another; and this is in the ſame Manner to be confined ſolely to the Earth, on the outer Edge of every Row, or to thoſe Outſides of each Interval which the ſingle Furrow of the Hoe Plow did not affect.

This is a Thing not altogether neceſſary, but it is uſeful; and will very well pay the little Charge it coſts, in the Encreaſe of the Crop.

While this ſecond Handhoeing breaks off the Ends of the ſhort and ſlight Roots within its Reach, the deep Furrow in the Centre of the Interval, cuts off the Ends of all thoſe longer and more ſerviceable Roots which had penetrated ſo far, and ſpread ſo wide, as ſome at this Period of the Peaſe's Growth will always have done; and from the broken Ends of theſe there will be innumerable others immediately formed, ready to draw Nouriſhment; and they will have a freſh broken Earth eaſily to ſpread in, and full of that Nouriſhment for them.

The Conſequence of this will be an immediate great Shoot of the Peaſe, and they will gather a ſurprizing Strength.

As to the Repetition of this Horſehoeing, the Farmer may be left wholly to his Diſcretion. If he do no more he will be ſure of a great Crop, for this new broken Ground will ſupply the new Roots, and all ſuch others as ſhall ſpread into it with a great Quantity of Nouriſhment all the Time the Crop is to be upon the Ground: but if he chuſe to repeat it twice more, the Advantage will be proportioned in his Crop, and he will be ſure of finding a manifold Return for the Expence.

If he will be thus adviſed, and will give his Crop three Horſehoeings, they are to be conducted in this Manner.

The firſt muſt be given a few Days after the Handhoeing of the Partitions; and the two others at equally diſtant Times between that and the beginning to pod.

In this Caſe the firſt Hoeing is to be performed as mentioned for the ſingle one, very deep, and in the Middle of the large Interval, between Pair and Pair of Rows. And the two following Horſehoeings muſt be more ſhallow, and muſt be carried in the middle Way between the firſt Furrow and the Rows.

Few will perhaps be at the Expence of ſuch a repeated Horſehoeing on a Piece of Peaſe, without ſeeing the Advantage thoroughly explained, but that is in itſelf ſo clear and evident, when the whole Compaſs of the Work is taken in, and the Benefit to the Crop conſidered, that we ſhall be able to ſhew every thinking Huſbandman it is to his real and great Profit.

Two Points are intended by the ſowing of Peaſe; the one to get a profitable Crop; the other to prepare the Land for Corn. Now both theſe will be anſwered in the higheſt Degree by this Method. His Crop will have the Advantage of ſuch a Degree of Nouriſhment, as could not be given to it any other Way, and the Produce will be great accordingly: and at the ſame Time the Land will be prepared for Wheat by ſuch repeated plowings, by Way of fallowing, that there is no Method whatſoever of making it ſo rich, or dreſſing it ſo well for that Grain.

CHAP. VIII.

Of reaping of Peaſe.

THE Peaſe being come to their Growth, are to be watched for the Time of gathering. This is to be timed carefully, for it is of Importance that the due Ripeneſs be obſerved. In the Plantation of Garden Peaſe in the Field, the common Method of pulling them as they ripen is to be followed; but in the Farmer's Concern, where they are not of that Kind, nor intended for that Uſe, they muſt be reaped at once; and it is on this Occaſion the finding the due Degree of Ripeneſs is of ſuch great Concern.

In the gathering by Hand Women are to be employed, and they are to be ſent into the Field daily, to gather as the Pods ſucceſſively ripen, ſo that the Profit riſes daily; and it is to be begun as ſoon as any are fit to pull, and continued as long as there are any in a Condition for Service left. For this there needs no particular farther Direction.

In the Farmer's Pea Field let there be all Care taken in examining the Peaſe, from the Time the Pods begin to ſwell. From this Period till their ripening, which is known by the Size and Firmneſs of the Pea in the Shell, the Owner himſelf ſhould every Day go into the ſeveral Parts of the Field, and open Pods in different Places.

All will not ripen together upon any Ground, but he will thus know when moſt are ripe together.

He will loſe ſome by ſheding, and ſome will be unripe at whatever Time he reaps them, but he is to contrive ſo as to loſe the leaſt by one or other of theſe Accidents. In general it is better to err on the Side of their being under ripe than the other; becauſe thoſe which are but moderately ripened, will thus harden in the drying; whereas, when the Field in general is too ripe, a great deal will be loſt by ſheding.

The beſt Method of reaping is by a Hook with a good Edge, faſtened to the End of a long Handle. A dextrous Fellow will do a great deal of Buſineſs in a Day with this Inſtrument, in a Field of Peaſe ſown in the common Manner; but in one where the Peaſe are planted regularly, the ſame Hand will go through ſuch a Quantity as is ſurprizing.

When the Peaſe are cut down, the Way is to leave them to dry a little upon the Ground; but when they lie in a ſcattered Manner there is more Harm than Good done by this.

The Reaper ſhould be ordered to throw them up in ſmall Heaps, as he cuts them, and thus they will lie conveniently, be leſs in Danger of Vermin, and ripen without ſheding.

Nothing is ſo eaſy as this toſſing them on an Heap, as they are cut with the long Hook; and this ſhould be done in ſo careful a Manner, that the Heaps may lie hollow and light: this gives the Wind free Play among them; and if Rain happens, they are in the leſs Danger of being ſpoiled.

When they have lain in this Manner till the Stalks and Pods are dried, and the leſs ripened Peaſe have got their due Firmneſs, they are in a Condition to be carried in, but that ſhould be done with Care and Diſcretion, that too much be not loſt in the ſhaking.

CHAP. IX.

Of Tares.

THE Tare is a low climbing or drooping Plant, reſembling the Pea in its Manner of Growth, but ſmaller. The Stalks are weak, and lean on the Ground. The Leaves are each compoſed of ſeveral Pairs of ſmaller, of a pale green Colour, and there are Tendrils for climbing or hanging upon any thing. The Flower reſembles that of the Pea in Shape, but is ſmaller, and of a mix'd Purple Colour in the common Kinds, tho' of various Hues in others. The Seeds are contained in ſlender Pods, and are round and ſmall. Their Colour varies like that of the Flowers.

There are two Kinds of Tares, the white and the black. Theſe are named after the Colour of the Seeds, and have little other Difference: they properly are only ſeminal Varieties of the ſame Species; the white Tare riſing originally from the Seed of the black, as the common blue and red Flowers of many Kinds, in our Gardens will occaſionally yield ſuch as are white. In the ſame Manner the firſt Variation in this Kind of Tare is, that the Flower is white, whereas it is purple in the other; and the Seeds afterwards are of the ſame Colour.

Either of theſe may be ſown in Fields, and they will anſwer the ſame Purpoſe; but the common or black Tare is the hardier Kind, and the beſt Bearer.

There may be a great Advantage in the ſowing Tares properly, among the Variety of Articles with which the preſent Practice of Huſbandry gives the Farmer an Opportunity of varying his Crop. They excellently prepare the Land for Corn, and their Produce is of a certain and not inconſiderable Price, being the proper Food of Pigeons, and uſeful to many other Purpoſes.

We have ſhewn the Profits of a Dove-cote, and hope the Reader has been made thoroughly ſenſible of them; wherever there are Pigeons there muſt be Tares raiſed or bought; and this is not their only Uſe, for the Straw, when well dried, is an excellent Food for Cattle. So that upon the whole, the Tare, though greatly inferior to many of the preceding Articles, yet is a very profitable, and very uſeful Crop at proper Seaſons.

CHAP. X.

Of the proper Soils for Tares, and the Management of the Ground.

THE Huſbandman will eaſily know, that if the Tare required a very rich Soil, or great Preparation for it, the Account we have given of its Value, would not make it worth his while to raiſe it; but this is not the Caſe: a very poor Land will ſupport it; and it demands little Preparation.

It is a hardy Product, approaching to the Nature of a Weed; and it will therefore grow either on Land naturally poor, or ſuch as is exhauſted: this is what makes the Farmer find his principal Advantage in its Culture: for it not only thus ſtands in the Place of Barrenneſs, but prepares the Ground for better Crops.

Although moſt Soils will do for the Tare, yet, like all other Plants, there are ſome that it affects more than others. This is a material Conſideration to the Huſbandman. The great Variety of Articles of late Years introduced into his Profeſſion, give him an Opportunity of varying the Crop on every Occaſion, and among theſe inferior as well as among the richer Kinds, he will find a double Advantage in a prudent Choice, which is moſt ſhewn in ſuiting the Species to the Nature of the Soil.

The moſt favourable Land for Tares is a good ſandy Loam. They will ſucceed excellently on mellow Earth, if not too moiſt for them, which is a very common Inconvenience in that Sort of Ground. They will ſucceed very well on ſandy Ground, that is not rich in any Reſpect; and we ſee great Crops of them in the Lime-ſtone Countries, and that frequently where there is very little Depth of Soil.

The worſt Ground for the Tare is a tough wet clayey Soil. In HERTFORDSHIRE, where a great Quantity are raiſed, they find them always ſucceed better on the hilly Grounds than in the Vales.

The Soil and Situation being thus fixed upon, there requires little Care in the making it ready for the Reception of the Seed. By this Choice we do not mean to tye the Farmer down ſo ſtrictly, as that nothing elſe will do but ſuch a Field as we have deſcribed, but when it happens that he has the Choice of two or three, and one of them anſwers this Character better than another, he ſhould take the beſt.

We will ſuppoſe the Field where they are to ſtand, has been pretty well exhauſted by the laſt Crop of Corn. In this Caſe no Preparation by Manure, or repeated Tillage is wanted: all that is needful is to plow in the Stubble; and let this lie to rot; and in Spring to open the Ground for the Seed: theſe Kind of Crops are ſo far from demanding Manure, that they ſerve as Manure to the Land themſelves; and of them all none more than this Species.

CHAP. XI.

Of the ſowing Tares.

WHEN the Land is ready, the next Thing is to take Care of the Seed, and in this the Huſbandman ſhould not be negligent: a little Care coſts nothing, and it enſures a profitable Crop.

Let the Seed Tares be bought or purchaſed by Exchange from ſome Farmer, at ten or twelve Miles diſtant. The Advantage and Uſe of this, in all Seeds, has been ſhewn already; and let the Farmer who is to ſow them take Care to purchaſe ſuch as have grown on a different Kind of Soil from his own.

Thus, if his Field be mellow Earth let him chuſe the Seed Tares from a loamy or ſandy Soil; and on the contrary, if his be ſandy let him chuſe the Seeds from one that is not.

Thoſe Tares are in general beſt for ſowing that are of a middling Size, round, full, and plump, of a ſmooth and bright Surface, and heavy. There is Reaſon the Huſbandman be careful in this Choice, becauſe few Seeds are ſo apt to ſpoil; and all Pains are thrown away upon Land where there is a Defect in the Seed.

The Tare does not grow well unleſs it have been full ripe when gathered; and if it have ſuffered wet in the keeping, it loſes a great deal of its Vegetative Power. Theſe are the two Accidents the Farmer is moſt to fear, and he will be guarded againſt them by the Rules we have given for his Choice. Such Tares as have been gathered before ripe, never get that Roundneſs, Fullneſs, or Weight we have recommended; and if they have been damp, ſo as to get Damage, they loſe their gloſſy Surface, and they do not recover that again.

The Seed being thus choſen, the Quantity is next to be conſidered; and in this the common Practice comes nearer what is right, than in moſt other Seeds. The general Error is the ſowing too much, and what Miſtake there is, is on the ſame Side here, but 'tis not great, about five Pecks are generally allowed to the Acre, but a Buſhel is fully ſufficient: three Pecks will be very well.

There is a greater Crop from a few flouriſhing Plants, than from a great Number which ſtarve one another.

The beſt Time for ſowing them is in the Middle of FEBRUARY. Very little Trouble need be taken about them, for the moſt ſlight ſtirring of the Ground is ſufficient; but of one Thing the Huſbandman muſt take eſpecial Care; which is, the finiſhing what he undertakes in this Way without Delay. There muſt never be more ſown in a Day than can be well covered before Evening; for if they lie expoſed to the Dews of the Night, they contract a Damp that decays a great Part of them; and the reſt grow poorly.

In general, a poorer is better than a more rich Land for Tares. In the former they pod well; in the latter, they are to run into Stalk and Leaf with leſs bearing. There is alſo another Misfortune attending the ſowing of Tares on rich Ground, eſpecially if it be a little moiſt, which is, they are more apt to lie upon the Ground, becauſe of the Weight of the Stalk, and then they rot.

There is an old Cuſtom among the Farmers of ESSEX, and ſome other Counties, of ſowing Tares and Horſe Beans together: they thrive tolerably well in this Way, but they do better ſingly. There is no Difficulty attending the reaping of them, for they may be very well cut together, when ripe, as they will be about the ſame Time; and the different Sizes of the Bean and Tare make them eaſily ſeparated in the Barn by a Riddle.

CHAP. XII.

Of the mowing and reaping of Tares.

THE Crop being in the Ground will require no farther Care of the Farmer, for they will ſhoot quickly, and grow vigorouſly, ſo that Weeds do not much thrive among them There are two Seaſons of cutting them, the one for the Straw, as it is called; that is, for the green Plant for the Food of Cattle, the other for Seed.

The firſt may be continued at different Times for ſeveral Weeks, and it is a very wholeſome and profitable Food; the other is only to be done at one Time, that is, when the Tares are ripe in the Pods; and for the knowing the exact Period for this, the Tare is to be watched in the ſame Manner as the Pea.

The cutting them for Fodder is often the moſt important Service they can be put to; as to the letting them ſtand for ripening, it is for Seed, or for Food for Pigeons; but as when the Farmer keeps any Quantity of theſe, as he muſt either raiſe or buy Tares, this is a conſiderable Article.

If a favourable Seaſon follow, the Time of ſowing the Tares will be fit to cut in MAY for foddering Cattle in the Rack; and, upon Occaſion, they may before that Time ſerve for feeding freſh in the Field.

The great Advantage of all theſe Crops of ordinary Pulſe is, that they cover and ſhade the Ground. The Tare being larger than ſome of the others, ſerves this Purpoſe better than they, and its Seeds, or the ripe Tares being of Uſe, is another Advantage, becauſe it may be kept longer upon the Ground. For this Reaſon, though the Farmer may occaſionally cut his Tares green, yet I adviſe him when he would give the Ground the greateſt Advantage from them, to let the whole Crop ſtand till ripe. In this Caſe the entire Field is covered for a very conſiderable Time, there are no Weeds ſuffered to grow in it, and the whole is mellowed by lying under the Covert of the Stem and Leaves of the Tares, while their Roots draw but little Nouriſhment to impoveriſh it. The Tares being then obſerved from time to time as they ripen, are to be reaped at the Period when they are fulleſt of rich Pods; and then left to dry in the Field in little Heaps, before they are carried home for getting out the Seed.

CHAP. XIII.

Of preſerving of Tares.

THE Farmer has ſeen how eaſily Tares are damaged by wet, the Conſequence of which is their growing mouldy, or muſty: after this they never recover their right Condition, Look or Value: but, beſide this, there is another Accident to which they are very liable, that is, the being infected with Worms, Mites, and other little Vermin. Now in this Caſe the pulpy Part is eaten, and they become light, duſty, imperfect, and of little Value.

We have told the Farmer how to manage them from the Sowing the Field to getting home his Crop; we muſt now acquaint him with the Ways by which the Produce may be preſerved from theſe Miſchiefs, for his certain Advantage in feeding his Pigeons, ſowing again, or ſelling.

The Preſervation of Tares from both theſe Accidents, depends principally on the drying of them; for, as it is Damp that moulds them, the ſame makes Way for thoſe little miſchievous Vermin, which are always found in damp Tares, but rarely in ſuch as have been properly dried.

We have directed their laying ſome Days in the Field, after cut, for the Pod and whole Plant to dry. After this, when the Tares are got out, they muſt be managed according to the Weather, but one Way or other they muſt be thoroughly dried.

If the Air be very warm and dry, the ſpreading and turning them on a Floor for ſome Days, will anſwer the Purpoſe; if otherwiſe, they ſhould be laid upon a Kiln: but, in this Caſe, the Heat muſt be very gentle, and well moderated, otherwiſe it may do more Harm than the Damp, deſtroying the vegetative Power in the Seed, and injuring it in its nouriſhing Quality.

When the Tares are thus properly ordered, they muſt be kept in a dry Place, and properly ſecured from Vermin. The thorough drying is very eſſential, for otherwiſe they will breed Diſorders in the Pigeons that are fed with them; and, when uſed as Seed, not one in ten will grow.

When they are to be kept any long Time, the beſt Way is to put them up in large Barrels; then ſetting them in a dry, cool Place, they will be out of all Danger whatſoever. I have known Tares thus kept that were good for all Purpoſes at fourteen Years after the Threſhing; and they probably would have kept good as much longer.

CHAP. XIV.

The Thetch, Fetch, or Vetch.

THere are few Occupations among the common Part of Mankind, that give Origin to ſo many ſtrange Terms as the Huſbandmans. We have been careful to explain them in the Courſe of this Work; and, we hope, by that Means have rendered not only our own, but the Writings of others more uſeful: the Subject of the preſent Chapter is an Inſtance. We ſee in moſt Books of Huſbandry written of late Time, the Name of the Thetch, a Plant recommended extreamly for the Improvement of Land. This is a Kind of Pulſe very well known by its Appearance, and by the Shape of the Seed, in the Counties where it is cuſtomarily raiſed: but how is the Farmer in a remote Part of the Kingdom, who wiſhes to bring home the Improvements practiſed in other Places, to know what is meant by this Word? No Dictionary will explain it to him, for there is no ſuch Word in the ENGLISH Language. If he look into the ENGLISH Herbals, he will not find it in any of their Indexes; nay, though ſome of them have a particular Table of barbarous Words, as they are called, the Word Thetch is not among them. The Reaſon is, that it is a Barbariſm of later Origin than the Time of their writing.

In ſome of the Books wherein Thetches are named, he finds them alſo called Fetches, but this is a Word as arbitrary and unmeaning as the former, there being no ſuch properly in the Language. In ſome it is, as they apprehend, farther explained by being written Vetches: but this is a Term that has worſe Conſequences than leaving the Reader in the Dark, for it creates Confuſion. There is ſuch a Word as Vetch in the ENGLISH Language, but it is the Engliſh of the Word Vicia in Latin, and therefore ſignifies the ſame with the Tare.

In the two other Caſes therefore, theſe Writers uſe Words that cannot be underſtood, becauſe they have no received Meaning at all; and, in the latter, they uſe a Word that means ſomething elſe.

If the Farmer in a remote Part of the Kingdom, ſhould from reading any of theſe popular Works, be induced to propagate the Thetch, he could never find any Meaning of that Word except the Tare; and he would therefore, after a great deal of Difficulty, find what they did not mean. Themſelves know what they intend by it, becauſe a Word will ſignify any Thing Cuſtom appoints; but one Purpoſe of this Work being to convey to the Farmer of one County, the Knowledge of another; we muſt make them underſtand one another's Language.

There is a Plant of the Pulſe Kind very frequent in the warmer Parts of EUROPE, the Flower of which reſembles that of the Field Pea, but its Pod is ſhort, and ſeems blown up. This they call in Latin Cicer, and its proper Name in Engliſh is the Chich. Some have called it the Chich Pea, others the Chich Vetch; and in ſpeaking of the Seed, the common Expreſſion is Chiches. When the Chich firſt was brought into Uſe among the ENGLISH Farmers, the Name puzzled them; and as they were accuſtomed to hear it ſpoken in the plural Number Chiches, they by one Miſpronunciation after another, called it Cheches, Thetches, Fetches, and Vetches.

This then is the Pulſe the Writers on Huſbandry mean by the Thetch, and under theſe Names

Names of Chich and Cicer, it will be found in the Writings of thoſe who have treated of Plants.

The Chich, or as our Writers call it, the Thetch, is therefore of the Pulſe Kind, but ſingular in the Shape of its Pod, and in other Particulars. We ſhall firſt make the Reader properly acquainted with its Nature, and its ſeveral Kinds, and afterwards with the moſt advantageous Manner of cultivating it for the Benefit of the Ground.

CHAP. XV.

Of the Nature of the Chich, and its Kinds.

THE Chich, like the reſt of the Pulſe Kind, is a weak and ſtraggling Plant. The Root is inconſiderable, wherefore it does not penetrate deep, nor ſpread far for Nouriſhment, ſo that the Ground is not impoveriſhed by it as by other Growths. The Stalks are numerous and weak, they will grow in the larger Kinds, three Foot long; in the leſſer two Foot; but always lie upon the Ground. This is far from a Diſadvantage to the Farmer, for by thus lying upon the Surface, they cover it the more perfectly; and make it light and hollow.

The Leaves reſemble in their general Form thoſe of the Pea and Tare, but they are more beautiful. Each is compoſed of three or four Pair of leſſer ones, and an odd one at the End, and theſe are all of a very pleaſant green, and notched round the Edges. The Flowers grow from the Bottoms of the Leaves, and are of the Shape of thoſe of the Pea or Tare, but ſmall. They vary in Colour according to the Kinds, being white, red, or duſky, and the Seed is of the ſame Colour, that follows them. The Pods that come after the Flowers are of the ſame general Structure with theſe of the Pea Kind, but they are ſhort, thick, and blown up as it were, and each contains only one or two Seeds. Theſe are not altogether round, but of a painted Shape in one Part, from whence fancyfull People have ſuppoſed they reſembled the Head of a Ram, and the Plant has been called the Ram Chich.

The Chich is a Native of ITALY, and ſeveral Varieties of it are cultivated in the Gardens of that Kingdom; as alſo of SPAIN, PORTUGAL, and the South of FRANCE. They raiſe them there as we do Peaſe, and for the ſame Uſe at their Tables; whence their Gardeners, as ingenious as ours, have made innumerable leſſer Varieties. But we are writing for the Farmer, and he is to raiſe them for a very different Purpoſe; therefore all the Diſtinction that he need regard is, that of the two Kinds which from their Size are called the larger and the ſmaller Chich, and from the Seaſons of ſowing them, the Winter and the Summer Chich or Thetch, the large one is the Winter Chich, for being more hardy it ſtands the Cold: the ſmaller one being tender, muſt be ſown in Spring.

The Kinds cultivated in Gardens Abroad are principally three, the white, the black, and the red Chich; they are called by theſe Names according to the Colour of their Flower and Seed; and are not there preferred to Peaſe, but are found better ſuited to the Countries. Our Pea is vaſtly preferable, according to the Accounts of the ITALIANS themſelves, both in its Taſte and Bearing, but it will not thrive ſo well with them as here; and theſe being natural to the Climate, are cultivated in a great Meaſure in its Stead. The ENGLISH Farmer is to count little upon the Fruit of this Pulſe more than for Seed, therefore he is to ſee it in a proper Light, altogether different from theirs: with him it anſwers two Purpoſes, the feeding his Cattle in the Stalk, not Seed; and the Enriching of the Ground.

This Enriching of the Soil depends partly upon the keeping it clear of Weeds, partly upon the little Nouriſhment it requires, and partly upon the Covering and Shelter it gives the Surface.

This laſt is the greateſt Conſideration; for, when a Piece of Ground is lightly, but thoroughly covered, and little exhauſted, it grows mellow, and becomes, with very little farther Expence, fit for the richeſt Crops. For this Reaſon the large Chich is to be preferred to the other as better covering the Ground: but this is not all its Advantage, for being ſown in Autumn, it provides an early Food for Cattle when they moſt want it.

Notwithſtanding this, the Farmer will find many particular Circumſtances wherein the ſmall or Summer Chich is preferable, with Reſpect to the Time of Sowing, the Nature of the Provender, and the Condition of the Ground.

CHAP. XVI.

Of the proper Soil for Cheches; and its Preparation.

THE Huſbandman is to conſider all theſe little Pulſes in a very different Reſpect from the valuable Grains; as to preparing the Soil for them, that lies in a very little Compaſs, for they are rather ſown to prepare the Land for ſomething elſe; but in the Choice of the Ground, there is a great deal to be conſidered.

He has a Variety of theſe, the Tare, the Chich, and the Lentil: they will all, with proper Management, anſwer the ſame Purpoſe to him, and they will thrive variouſly on different Soils; therefore he is to underſtand what Kind ſuits each, that he may have the double Advantage of enriching his Ground, and increaſing his Crop. For it is particular in theſe Species, that the larger they grow, and the more they yield as Fodder, the more and better they improve the Ground for a ſucceeding Crop: this will be eaſily underſtood from what we have ſaid before on that Head.

As the Tare loves a dry Soil, the Chich will bear one that is ſomewhat damp. It is a proverbial Saying among the Huſbandmen, that no Rain will kill a Thetch, and the ſame Quality of bearing heavy Showers while young, for that is the Seaſon of them, will render it capable of living in a Soil naturally chilled by wet: but this

this muſt not be carried too far. Chiches will not live on a Bog. In all Things there muſt be Moderation.

The beſt Soil for the Chich is a ſoft mellow Earth: the Farmer would not allow this Crop a Piece of freſh Ground for that Purpoſe, but it will thrive excellently upon a rich Field of this Kind after Barley or other Corn.

Such a Soil as this would be excellent, as we have ſaid, for Tares, but there may be Accidents wherein it would fail for that Crop, and yet notwithſtanding which, it would be excellent for the Chich. Thus if a mellow Soil be upon a hard Gravel, that will excellently ſerve for Tares, becauſe the Wet which falls will get through the lower Bed, after it has done its Office to the Roots of the Plants; on the other Hand, if a mellow Earth have a Bed of Clay under it, Tares will not grow upon it, becauſe the Clay holds the Water too much, will chill their Roots, and make the Plants poor and yellow. Now ſuch a Piece of Ground as this will do excellently for Chiches indeed, better than any other: this is a Sort of Difference the Farmer ſhould remark carefully; one of theſe Soils will do for one, the other for the other Crop; and he who if he had ſowed without Conſideration, might have had very indifferent Crops of both, will, by thus examining the Soil, and ſuiting the Crops to it, have very good ones from both.

After a good rich mellow Earth, the beſt Ground for the Chich is a ſtiff Loam.

Loams may be conſidered as Soils of quite different Qualities, according to the various Compoſitions or Quantities of the Mixture. All of them have ſome Sand and ſome Clay: but when the Sand is in the greateſt Quantity, they are looſe and warm Soils; when the Clay, they are ſtiff and binding. In the former Caſe their Dryneſs and Warmth make them very fit for the Tare; and, in the latter, their Stiffneſs and binding Quality retaining Moiſture, make them ſuit the Chich.

The proper Soils being choſen, there is little Trouble in preparing them, but ſome Difference in the Manner of working when the Seed is to be let in, according to the Nature of the Ground.

All that is required for theſe Crops, when they follow Corn, is to plow in the Stubble; this ſoon rots, and is all the Manure that is, or need be allowed for them, the Ground will be in ſufficient Heart to produce them.

CHAP. XVII.

Of ſowing Chiches.

THE proper Management of theſe leſſer Pulſes is ſo conſiderable an Article in the whole, though leſs in their immediate Value, that they are very well produced in a Year that would have been uſeleſs in that Reſpect, being the Time of Fallow; and when they are eaten upon the Ground under proper Regulations, they give the Land, by Means of the Dung and Urine of the Cattle, a very good Dreſſing.

The large or Winter Chich, is to be ſown the firſt Week in October, or thereabouts, and by this Means it will get a good Root, and a ſtrong Head, and will be able to ſtand againſt the Froſts; and, when Spring comes, will puſh ſo vigorouſly, as very ſoon to be in a Condition for eating on the Ground; or mowing for that Purpoſe.

The leſſer Chich, called the Summer Thetch, ſhould be ſown in the Middle of February. The Rains that naturally follow at this Seaſon, puſh it up in the Shoot, ſo that in a favourable Time it will be ready for cutting in the End of May, or very well in the Beginning of June, and may be eaten upon the Ground ſooner. The Winter Thetch, if ſown early in October, will be ſo well grown by Lady Day, that Sheep and Lambs may very well be fed upon it; and this is a Seaſon when proper Food is ſo much wanted for them, that they may very well pay the Expence of getting it up ſo ſoon.

The firſt Thing to be conſidered toward the Sowing, when the Land is ready, is the Choice of the Seed; and after what we have ſaid with Regard of Tares, a few Words will give the neceſſary Information in all Pulſe: the Danger is, that there are Vermin, and that there have been Damps, this may be diſcovered by the dead Look, or the duſty Appearance of the Seed; and, in either Caſe, that is to be rejected. Let the Farmer chuſe ſuch as is bright, weighty and free from Duſt, and he will not be diſappointed.

The Quantity would naturally come next to be conſidered, but in this, as the Manner of Sowing, ſuited to different Soils, makes ſome Variation that muſt be explained firſt.

If the Soil be clayey, or of a ſtiff Loam, the Manner of Sowing muſt be this. The Ground muſt be broke with the common Wheel Plow, and the Seed ſcattered in by Hand in that Manner the Farmers call ſpraining of it, in Ridges. It is thus to be plowed in; and after this, the Land is to be harrowed even, only leaving Water Furrows between the Ridges.

In this Manner the Accidents attending leaving the Seed uncovered, which are the ſame with Reſpect to the Chich, that are in the Tare, are prevented. None of the Seeds are left expoſed to the Dews of the Night, which would have very bad Conſequences.

When the Soil is a mellow Earth, with a proper Bottom, I ſhall adviſe the Farmer to ſow his Chiches in broad Lands, with a ſingle Plowing, harrowing them well in.

The Uſe of the Crop is alſo to be conſidered before the Sowing, that a proper Method may be taken to prepare in Time for it. Thus ſome are of Opinion, that eating on the Ground is beſt, and others prefer the Mowing and carrying off. This, when the Land is of a middling Nature, may make a Difference in the Manner of Sowing; and when any one of theſe two Methods are rendered neceſſary by the Quality of the Ground, the Huſbandman muſt conform to that Neceſſity, rather than to the common Opinions. We mean this. When Chiches are ſown on Ridges, they ſhould be eaten upon the Ground, becauſe Mowing is difficult in this Condition

Condition of the Land; on the other hand, when they are ſowed in broad Lands 'tis beſt to mow them.

In general mowing is much the beſt Method. All Cattle tread down and deſtroy more than they eat, and it is a Certainty in general, that the Produce of one Acre mowed and carried to the Rack, will go as far as that of two eaten upon the Spot.

As to the eating of Sheep and Lambs they do leſs Damage than ſuch Cattle as have broader Feet, and their Dung and Urine, and the Moiſture from their Bodies where they lie, gives a Richneſs to the Ground that may, in many Caſes, make amends for the Damage: but this is not the Caſe with Horſes. In wet Seaſons they cannot be turned in at all; at beſt they deſtroy a great deal by their ſpreading, heavy Feet, and they can come upon the Ground but once; whereas the ſame Crop may very well be eaten twice by Sheep and Lambs in Spring.

The Nature, Manner, and Differences of plowing being thus underſtood, we may ſpeak of the Proportion of the Seed which varies accordingly.

When the Chiche is ſown on Ridges, after Wheat or Barley, two Buſhels and a half of the large or Winter Sort will be a proper Allowance to the Acre, and of the ſmall Sort three Buſhels. When it is ſown in broad Land three Buſhels of the large, and two and a half of the ſmall, is the proper Allowance. In either Caſe this is proportionably a much larger Allowance of Seed, than we recommend on other Occaſions, but the Difference is proper when we conſider the Nature of the Crop.

In moſt other Kinds we depend upon their Produce in the Grain or Seed, therefore a few Plants well nouriſhed is what we ſhould aim at; becauſe theſe will yield a better Crop than a large Number that are ſtarved: but here the Farmer does not form his Expectations of any ſuch Crop. Two Points are to be obtained by the Chiche, firſt the covering and mellowing the Ground; and ſecondly, the ſupplying his Cattle with Food. Now both theſe will be beſt anſwered by the Chiche growing cloſe. If he was to depend upon the Produce in Seed, he ſhould not ſow more than two thirds of this Quantity.

CHAP. XVIII.

Of the Management of Chiches, and their ſtanding for Seed.

WHether it be in Autumn or Spring the Chiche is ſown, it requires no farther Care from the Owner. After it is once harrowed into the Ground, it will riſe quickly, and ſhoot ſtrongly; and being ſown thick it will deſtroy all the Weeds that ſhall attempt to riſe among it. In either Caſe therefore he is to leave the whole to Nature and wait her Progreſs, obſerving the Growth from time to time, to find when it becomes fit for being eaten: and in this he is to conſider alſo the Condition of his Stock, and their other Provender; for he may find it profitable to turn in his Sheep and Lambs a Week or two before he could wiſh, for the Sake of the Chiches, when they would elſe decline for Want of proper Food.

In general the Winter Thetch or Chiche comes in much earlier than the Spring or Summer Kind, but the latter is the beſt and wholeſomeſt Food for Lambs, and is what they always eat the moſt freely.

This does not cover the Ground ſo well as the larger, nor lie upon it ſo cloſely, nor yield ſo large a Crop of Stalks and Leaves; but ſtill there are Advantages. We have ſaid it is beſt for the ſmaller Cattle, and ſhall add what perhaps few have obſerved in its Favour, that it grows up much ſooner after cropping than the other.

In general I have obſerved, that the Winter Thetch ſucceeds beſt on broad Lands, and the ſmall or Summer Kind on Ridges. I name this the more punctually, becauſe in this County (Middlesex) the Cuſtom is the contrary Method in moſt Caſes. The large Thetch is beſt for mowing, and the ſmaller for eating on the Spot: and this is a farther Reaſon why the ſmall ſhould be ſowed preferably on Ridges.

We have already obſerved what neceſſary Differences the Nature of Soils may make in this Article, we ſpeak here of what is beſt when the Choice on that Account is indifferent.

As to the Uſe of Chiches we have ſhewn that the ſtanding for Seed is the leaſt, yet it is needful ſome Seed ſhould be ſaved, and therefore tho' a leſſer Article, ſome Care muſt be taken about it. In this the Farmer, as in all other Matters, ſhould prepare in Time, by properly looking forward.

If he have ſown two Fields with Chiche, that which is drieſt is the moſt proper for letting them ſtand for Seed; if only one, he ſhould ſee which is the drieſt and warmeſt Part of it. In either Caſe he muſt ſet aſide ſuch a Piece as is convenient for Seed, keeping Cattle off it by fencing, or if Horſes by ſtaking them down.

This is what he is to do in the Growth, but he will find his Account in conſidering it at the Time of ſowing.

Let him, when he orders his Field to be plowed up for this Purpoſe, ſhew the Seedſman the Spot he fixes upon for letting his Crop ſtand for Seed, and then order him to ſtrew the Seed there more ſparingly. Half the uſual Quantity will be ſufficient for this Spot, and he will get more Seed, and better than if he allowed the whole. He will ſoon ſee the Difference in the Growth of the Plants; and it will be proper to have this ſmall Part where they are ſet for Seed once weeded.

Theſe are to ſtand undiſturbed till the Seed is thoroughly ripe in the Pods; and then are to be reaped together and threſhed, after a gentle drying.

The Seed thus obtained is to be ſpread upon a Floor and dried. It will be adviſeable for the Owner to exchange this with ſome diſtant Farmer, rather than ſow it again himſelf; but he will ſee by the Look and Condition of his own, when thus carefully dry'd, how the other ought to look when good.

CHAP. XIX.

Of the Manner of feeding with Chiches.

THE proper Part being ſet aſide for Seed, the Farmer is to conſider the reſt as the Food of his Stock, and to contrive in the beſt Manner for the ſpending it among them. The Growth is to determine his Conduct, but in order to manage rightly he muſt always keep in Mind, that there are three Ways of uſing it: firſt, by turning in of Cattle: ſecondly, by cutting it green for them: and thirdly, by making it into Hay. In either Caſe it is a very deſireable and very wholeſome Food.

The Cattle are fondeſt of it when they eat it upon the Ground: it is the moſt profitable when mowed green, and given them in Racks as cut; but it is the moſt wholeſome of all when dried. In this latter State Cattle reliſh it very well, and according to its Condition will prefer it to other Foods. The larger it is the coarſer Hay it makes, the ſmaller the finer and more tender.

For this Reaſon the little Chiche makes the beſt Hay in general; but the large Kind, when not too rank, anſwers very well.

The Huſbandman having theſe ſeveral Uſes in Mind, will manage his Crop accordingly. He will cut it at proper Times and in proper Quantities, and will conſider that the Value depends on the Age and Kind; he will therefore allow the proper Portions for feeding, and at the proper Times, and will take his Opportunities of cutting and drying ſome of the beſt and choiceſt of the Crop, when it is of ſuch a Growth as will render it moſt agreeable to the Cattle.

In this his Conſideration may extend beyond the common Conſideration of the Growth. He may recollect at what Time it will be uſeful to give his Lambs a feeding of the fine young Shoot of the Thetch, and cut ſome of the beſt Parts of the Ground accordingly. The Plants will grow up a great deal quicker when they have been mowed, than when they have been gnawed in eating; and he will have here a Kind of ſecond Spring, wherein there will be tender, delicate, and wholeſome Food for his Lambs, at a Time when he could not have got it in the ſame Condition any where elſe; and when they would not have fed willingly upon the natural large Growth.

When the Chiches have been thus managed, during the Summer, the Owner will find he has made a very good Uſe of his Field in their Product and Uſe, but he is to know the greateſt Advantage is behind; for his Land which was before in ſuch an exhauſted Condition, as to require the Refreſhment of a Fallow, has all the Time it was nouriſhing this uſeful Crop been getting into Heart, and will yield him another Crop of ſome more profitable Kind, without farther Expence or Trouble.

The Condition and Nature of the Field is to direct him what to undertake on this Head, but he has his Choice of Wheat or Turnips in the firſt Place, and if he diſapprove theſe, of almoſt any other Kind.

When a good Piece of Ground has been thus covered with a full Crop of Chiches, it will, by Michaelmas, be ſo mellow and fine, that he may ſow Wheat upon it with great Succeſs.

If he chuſe Turnips they may be ſown with one plowing and well harrowed in, and there will be no Reaſon to fear an early and a profitable Crop.

We have, in a former Part of this Work, mentioned the Principal of the great Corns and Growths among which the Huſbandman may, on this Occaſion, take his Choice; and we ſhall hereafter treat of Coleſeed: there are few Things more profitable than this, under good Management; and it never comes better than after a good Crop of Chiches.

The Winter Chiche we have ſhewn is the moſt profitable, becauſe of its coming in ſo early for a green Food, when there is a Scarcity of other Kinds; and we have obſerved alſo, that it covers the Land the beſt, and does it moſt good; but it is proper we add an Account of what there is againſt it, that the Farmer may not be raſh in determining for it againſt the other on all Occaſions.

The great Diſadvantage of the large or Winter Chiche, is the Uncertainty of the Crop; for it ſometimes periſhes altogether by Froſt. 'Tis no very uncommon Thing to ſee a Crop of it ſtand through the whole Winter, and periſh in February, or even in the firſt Week in March by the Severity of Froſts that come after hot Days.

On the other hand, the Spring ſowing is always ſafe; and as the ſevere Weather in February will often check thoſe Crops of the Michaelmas ſowing, which it does not deſtroy, theſe Spring ſown ones coming up quick, and meeting with no Stop, overtake them.

There is not a better Food for the Horſe than freſh mown Chiches, he will eat them freely, and they take at firſt the common Effect of green Food in a very kindly Manner; after which nothing puts him better in Fleſh.

It is of the ſame Advantage in fattening of horned Cattle; and it is in a particular Manner ſuited to Cows, becauſe it, at the ſame Time that it fattens them up, makes them yield a large Quantity of Milk, and does not give it that ill Flavour which it often gets from the feeding on ſome of the artificial Graſſes.

The Ewes, while they feed on it, have the ſame Advantage, fattening themſelves while they ſupply their Lambs with Abundance of fine and rich Milk.

The Advantages of this Pulſe are not ſufficiently known: it is one of thoſe but newly got into Uſe, and only in ſome Parts of the Kingdom. We ſhall be happy if we can recommend it to the Farmer in ſuch a Manner that it may become univerſal.

CHAP. XX.

Of Lentils.

THE Lentil is another of the ſmall Pulſe Kind, which has not been ſufficiently known in the early Practice of Huſbandry, nor is enough underſtood at preſent. It is a very profitable one, and we ſhall endeavour, for that Reaſon, to render it more univerſal.

The common Language of the Farmers in thoſe Countries where this Pulſe is moſt propagated, is giving it a new Name: they drop half the Word, and commonly call it the Till or Tills.

The Lentil is of the ſame general Kind with the Tare and Chiche, and it more agrees with this laſt than any other, becauſe it has a ſhort Pod: but this is not ſo blown up as that of the Chiche, nor have the Seeds that remarkable Figure we have named in thoſe of the Chiche, by which they reſemble the Head of a Ram.

The Lentil is one of the ſmalleſt of the Pulſe Kind. Its Root is little and inconſiderable, and its Stalks numerous and ſpreading, ſo that it agrees with the Chiche in that it covers the Ground well, and draws very little Nouriſhment from it, ſo that it has the ſame Kind of Benefit in the improving of Land; but this it does in a Manner inferior to the Chiche, becauſe it is ſmaller. We have ſhewn that the large Chiche does this much better than the ſmall Kind; and the Lentil is inferior to both, becauſe it is leſs than either, but yet it has in a proper Degree this Advantage.

The Stalks of the Lentils are a Foot and a half long and weak, the Leaves are compoſed of ſeveral Pairs of ſmall ones, and are of a pale green Colour, they differ from thoſe of the Chiche in that they have no odd one at the End; for there is a Tendril in that Part intended by Nature for the Plant's laying hold of any thing to ſupport itſelf.

The Flowers of the Lentil are little, and naturally rediſh, but they are ſometimes of a deep Purple, and ſometimes white: the Pods are ſmall, and there are uſually only two Seeds in each.

The Lentil, as it is of the ſame Nature with the Chiche, ſo they ſerve the ſame Purpoſes. They may be eaten upon the Ground or in the Rack, and are good either green or dry. They are a very good Food for Horſes, fattening them and keeping them in Health and Strength. Sometimes when eaten too greedily green they throw them into Diſorders, but this may always be prevented by giving them in a proper Manner. The beſt Way of Horſes eating them is dry. They are alſo good for Cows, Sheep, and Hogs; for the former in the Leaf, and for the other when in Fruit. They require no Care after they are in the Ground, and very little Charge in getting them into it, ſo that every thing recommends them: and we hope to ſee them as well known in the moſt remote Parts of the Kingdom ſoon, as they now are where Improvements are more frequent.

CHAP. XXI.

Of the proper Soil for Lentils, and the Manner of ſowing them.

THERE is always an Advantage to the Huſbandman, in having Crops that will grow upon poor Land; and this of the Lentil is one. We have ſeen that the Chiche will thrive upon Ground that has been exhauſted by Corn; but the Lentil will ſucceed on ſuch as is naturally poor, and has been exhauſted into the Bargain.

The Chiche and Tare never do ſo well as in good Garden Mould, but the Lentil thrives upon ſandy, gravelly, or chalky Soils; it is not under that Neceſſity of wet that the Chiche is, but will come to good where there is but the leaſt Fund of Nouriſhment. In the pooreſt, hungrieſt Loams the Lentil yields a good Crop; and never fails to leave that or any other Land in a much better Condition than it was before.

The Land requires little Preparation to fit it for Lentils, and they are to be ſown in Spring. As they are ſmaller they are alſo tenderer than the Chiche, and they muſt not be ſown ſo early. The Middle of March is as proper a Time as can be choſen for this Crop; and the End of that Month, or the Beginning of April, will do very well.

We have ſaid before that this Pulſe is ſo ſmall it does not well cover the Ground, for which Reaſon it does not anſwer the Purpoſe of enriching it like the other Kinds: it may be ſown therefore with Oats or Barley; and will thus anſwer different Purpoſes. Oats and Lentils will grow very well together; and as they will be ripe about the ſame Time, they may be reaped together, and threſhed together, after which they will very eaſily be ſeparated by throwing: the Oats being lighter will fly fartheſt, and the Lentils from their Weight, and their ſmooth round Form, which the Air lays no Hold of, will drop by the Way.

When they are ſown with Barley they may be ſeparated in the ſame Manner; and if a little Care be taken in the throwing, there will be very little farther Trouble.

The Seed Lentils ſhould be plump, ſmooth, and ſhining, for this ſhews they are freſh and ſound: and the Farmer will do well always to exchange Seed with ſome other at a Diſtance, who occupies a ſomewhat different Kind of Land. This being to the mutual Advantage of both there never is any Difficulty. According to the Service for which the Lentil is intended, a different Manner of ſowing will be proper. It is very uſeful to be eaten in the Stalk, but it is alſo worth Regard as to the Seed. In this it is greatly preferable to the Chiche, becauſe the Pods are vaſtly more numerous, and the Seeds are not only produced in greater Quantity, but are much more valuable.

The covering of the Ground being leſs a Conſideration in this Reſpect, gives a new Method of Culture at the Farmer's Diſcretion for this Species, that is, by the Drill and Horſehoeing

Method. The Lentil will thrive excellently on the pooreſt Ground under this Management; but that is not a Reaſon why it ſhould always be preferred; on the contrary, we ſhall adviſe the Farmer, on ſome Occaſions, to prefer the other.

Before he ſows his Ground with this Pulſe, let him conſider what is the principal Uſe whereto he intends to put it. If he deſign it for eating, whether freſh or dry, whether on the Ground or in the Rack, let him by all Means ſow it in the common Way, juſt as we have directed with Reſpect to Chiches; but if he have his Eye principally on the Seed, let him by all Means ſow it by the Drill, and in ſuch Manner that it may be horſehoed.

This naturally infers a great Difference, with Reſpect to the Quantity of Seed.

When Lentils are ſown for feeding in the common Way of Huſbandry, the proper Quantity of Seed is a Buſhel and half to an Acre: if it be intended for Seed, and ſown by the Drill, three Pecks is a very ſufficient Quantity, and the Plants will yield more than if twice as much Seed had been uſed.

In this Caſe the beſt Time for ſowing them is the third Week in March, and they ſhould be ſown in double Rows, with about eight Inches between them, and with ſuch Intervals between Row and Row, that the Horſehoe may conveniently come in.

In this Caſe the Produce will be very great; and this is the beſt Way of ſowing them on poor Land.

CHAP. XXII.

Of the Management and Uſe of Lentils.

THE Lentil, as ſown in the common and Drill Way, requires to be ſpoken of diſtinctly. If it be ſown by Hand, nothing is needful to be done, for it will riſe thick and deſtroy all the Weeds that attempt to riſe among it. When it is ſown by Drill, the Horſehoe muſt go once through the Middle of each Interval, when the firſt Shoot of the Weeds is up; and then no more Trouble is neceſſary. In this latter Caſe, as they are to grow for Seed, no more need be added, but that they are to ſtand till ripe, and then to be reaped dried, by lying in little Heaps in the Field, and then threſhed. But in the other Manner more is to be ſaid about them.

If they be ſown in the common Way, with Oats or Barley, they muſt ſtand their Time, and take their Chance with it; and when ripe muſt be thraſhed together and ſeparated, as we have ſhewn: but when they are ſowed alone, in the common Way of Huſbandry, there requires Care and Conduct in the Management of them.

Some in this Caſe are to be left to ſtand for Seed, but the greater Part is to be eaten upon the Ground, or mowed for that Purpoſe.

Lentils will not grow up after cutting or eating, ſo free as the Cliche, but they afford a good Supply at the cutting. For all Purpoſes the cutting and drying is the beſt Method. The Ox, Cow, and Horſe are very fond of the Lentil cut and dried, and it nouriſhes them greatly, but there is to be a Time obſerved for the cutting, according to the Beaſt that is to be fed with it.

The beſt Time for cutting it for Oxen and Cows, is when the Pods begin to fill; but for Horſes it is beſt when the Lentils are nearly ripe in the Pods. It muſt not be let to ſtand till they are quite ripe, for then the Stalk and Leaves loſe a great deal of their ſtrengthening Quality; but juſt when the Seed is large, and they are not decayed, the Lentil ſerves them both as Hay and Corn.

The Seed is not unworthy the Notice of the Farmer, with Reſpect to his Family, for it is very wholeſome, and not at all unpleaſant.

When Lentils and Barley have grown together, they may be ground together, and will make a very wholeſome and pleaſant Kind of Bread; and being boiled in the Manner of Peaſe, they are eatable, and in the Opinion of many pleaſanter than the beſt Peaſe. They are excellent eaten in the Straw, to make Cows give Abundance of Milk, and they give it no ill Taſte; and there is no Plant whatſoever that better aſſiſts the Ewe for the Suckling of her Lambs.

CHAP. XXIII.

Of Buck-wheat.

AT the End of this Account of the Farmer's leſſer Crops, of theſe ſeveral Kinds, we ſhall add one of a ſingular Nature, and then cloſe the preſent Book, this is Buck-wheat, called in ſome Places Brank; it is very different in Kind from the ſeveral Plants before-named, but it is cultivated in the ſame Manner as an Herb that may yield ſome Profit, and at the ſame Time improves the Ground whereon it grows.

Buck-wheat is an upright and pretty Plant, it grows a Yard high, and has a ſtiff, firm, and round Stalk, which divides toward the Top into ſeveral Branches. The Leaves are broad, they are forked at the End next the Stalk, and pointed at the other, and they are of a pale Green, often yellowiſh. The Flowers ſtand on the Tops of the Branches in large Tufts; they are ſmall and white, and the Seeds follow, which is of a triangular Shape, large and brown on the Outſide, but with a white Kernel within. Each Flower of the Buck-wheat conſiſts of one white little Leaf, divided into five Parts, and has no Cup. Among the Writers on Botany, ſeveral have called this a Cup, and ſaid that the Buck-wheat has no Flower properly ſo called. Within this are eight little rediſh Lumps, which contain a ſweet Juice, ſuch as there is in moſt Flowers, in greater or leſſer Quantity. Theſe form what is called the Nectarium of the Flower. In the Centre there grow eight ſlender Threads, of the Length of the Flower, with little Buttons at their Ends; among theſe ſtands the Rudiment of the Seed: this is of a three ſquare Form, and has three thready Subſtances growing to it, which are tufted at the Ends: theſe ſerve to catch the Duſt from the little Buttons, on the Tops of the

other Threads for the ripening of the Seed. One Seed follows every Flower, and the Flower itſelf ſerves it as a Covering, growing dry without falling, and clinging round it. This is one Reaſon why it has been called a Cup, rather than a Flower. The Cups of Plants frequently remaining with the Seeds, but the Flowers not.

It is a Native of the Eaſt, and is uſed in ſome Parts of the World for making of Bread. It is called by Writers on theſe Subjects Fagopyrum, and ſometimes Trionum. We meet with this laſt Name in ſome Books of Huſbandry, but the Authors have a very good Reaſon for ſaying little about it, for they do not ſeem to underſtand the Meaning of the Word.

There are two Uſes in the ſowing of this Crop, the one that its Seed is of ſome Value, the other that it will ſerve as a Manure; or as the Farmer's expreſs it, a Lay, whereon to ſow Wheat or Rye; but in this Caſe there is a particular Method to be uſed, for nothing is ſo advantageous, as the plowing it in entire at a proper Growth.

CHAP. XXIV.

Of the Soil for Buck-wheat, and the Manner of ſowing it.

BUck-wheat will grow on the moſt barren Lands, and this is one of its great Uſes to the Farmer. The dryeſt and worſt will afford it Nouriſhment. If he have a Piece of almoſt heathy Land, or of naked Gravel, or in the Stone Countries, one of thoſe Lands where Chips and Fragments of Stone make up, in a Manner, the whole Surface, Buck-wheat will grow on any of them. It requires little Preparation, and needs not be ſown till very late; ſo that every Way it recommends itſelf to his Regard.

When he has fixed upon a Piece of Ground, ſo poor that it will bear nothing elſe; or one that may, by this Means, be rendered fit for ſomething better, his next Thing is to ſeek for good Seed.

He is to chuſe the faireſt and ſoundeſt he can get, ſuch as is dry and of a bright Colour is beſt; but this is in general a Seed in which there is leſs Hazard than moſt others.

The Quantity is to be very different, according to the Deſign of ſowing; for when Buck-wheat is raiſed for Seed, a ſmall Number of Plants well nouriſhed is what the Farmer is to deſire; but when it is ſown only to be plowed in as a Manure, the Seed being not at all concerned in this Matter, the larger a Quantity there is upon the Ground the better.

When Buck-wheat is raiſed for the Seed a Buſhel is ſufficient for an Acre; but on the other hand, when it is meant by Way of Preparation for another Crop, four Buſhels to the Acre is not at all too much. The Time of ſowing Buck-wheat as already obſerved, is later than that of almoſt any other Crop. The Beginning of MAY is the earlieſt it ſhould be put into the Ground: the Middle of that Month is a better Time, and it will do to the very latter End. Buck-wheat being a Native of very warm Climates, does not bear Cold, and it is ſo quick a Grower that it needs not be ſown early in the Seaſon; for when got into the Ground toward the End of MAY, it will very well ripen during the Summer Seaſon.

After Buck-wheat is in the Ground there requires no particular Care to be taken of it. The common and familiar Method of plowing and harrowing, and that in the ſlighteſt Manner, covers it, and it will ſhoot at its own Time, let the Weather be what it will: Rain or dry makes very little Difference.

When once cut up it grows apace. The Sort of Grounds allowed to it does not favour the Growth of Weeds, like richer Land, nor do they grow ſo quick upon it; ſo that the Buck-wheat thriving apace, quickly gets the better of them. In this Condition it will continue growing up till it comes to flowering, unleſs the Intent of the Farmer be to plow it in ſooner.

CHAP. XXV.

Of the Management and Uſe of Buck-wheat.

BEſide the two Uſes of Buck-wheat in the Seed, and in plowing into the Ground, it has another very conſiderable one, which is, the being eaten by Cattle. This is the more important, becauſe it comes in at a Time when other Provender is ſcarce, the Graſs being burnt up by the Heat; and the horned Cattle at this Time, toward the End of Summer, being generally in great Want of good freſh Food. The Buck-wheat being then juſt coming into Bloſſom, the Cows are very fond of it; and it is an excellent Nouriſhment, rich and wholeſome, makeing them yield a great Quantity of Milk, and not giving it any diſagreeable Taſte. There is no better Butter or Cheeſe than ſuch as is made of their Milk when they have fed in this Manner.

If the Farmer intends his Crop for this Uſe, he muſt ſow it thicker than for Seed, but not ſo thick as when he intends it for plowing in; two Buſhels and a half of Seed to an Acre will yield a very good Growth for this Purpoſe.

After the Cows have eaten it down, the Stubble may be plowed in, and the Land will do very well for a Crop of Rye. It is not ſo well as when the large full grown Crop, ſown for that Purpoſe, is plowed in entire, that being the beſt Method of making this Crop proper for Wheat.

When this has been the Intent of ſowing, the Crop is to ſtand till full grown and in Flower, but not till the Seed is formed. Juſt before that it is in the richeſt Condition for Manure, and that Opportunity is to be taken.

When the Seed is the Point in View, and the Field has been ſown ſparingly for that Purpoſe, the Plants will be much ſtronger, and they will ripen a great deal.

At this Time the Farmer is to watch when moſt is ripe and none fallen, and then he is to get in his Harveſt.

Buck-wheat may ſtand longer than almoſt any Kind of Crop for this Purpoſe, for none holds the Seed ſo firmly. But ſtill there is to be ſome Regard to the Ripeneſs; and when but little is left that can come to good, the whole is to be cut, that more than its Value be not loſt in waiting for it.

The Way of gathering it is by mowing; and when down it is to lie ſome Days in the Air before it is houſed; there is no great Danger of Accidents during this Time, for ſcarce any thing is ſo hardy. When the Stalks are grown limber, and the Grain firm, it is to be carried in and thraſhed. The Produce is very great. Fifty Buſhels for an Acre may be had from very moderate Land, and much more is common from ſuch as is any thing rich.

The Uſes of the Seed are many, it ſerves excellently for Hogs, who are fond of it and fatten very well upon it: many Kinds of Poultry alſo like it; and in ſome Countries it is eaten by the poorer People, made into a Kind of Pancake, with ſome Wheat Flower among it. It is a thriving Food for Horſes. But it ſhould be broke in a Mill before they have it, otherwiſe the Skin is ſo tough it paſſes through them without doing them any good. Cattle will alſo eat the Straw, but it is not nearly ſo nouriſhing as the Grain.

End of the Sixth Book.

A COMPLEAT BODY OF HUSBANDRY.

BOOK VII.

Of NATURAL *and* ARTIFICIAL GRASSES.

In TWO PARTS.

CHAP. PART I.

1. *Of the Diviſion of natural Graſſes into Meadow and Paſture.*
2. *Of Graſs Grounds that lie high.*
3. *Of Graſs Grounds lying low.*
4. *Of Accidents to which Graſs Grounds are liable.*
5. *Of clearing a Graſs Ground from Ant-hills and Mole-hills.*
6. *Of clearing a Graſs Ground from Stumps and Buſhes.*
7. *Of improving moſſy Paſture Ground by burning.*
8. *Of improving common Graſs Ground by Manures.*
9. *Of the general Management of Graſs Ground.*
10. *Of Mowing.*
11. *Of Haymaking.*
12. *Of the Aftermath and Winter Uſe of Graſs Grounds.*

CHAP. PART II.

13. *Of the artificial Graſſes in general.*
14. *Of the beſt Soils for Clover, and the Manner of ſowing it.*
15. *Of feeding upon Clover.*
16. *Of mowing Clover, and its Hay.*
17. *Of the Soil for Saintfoine, and its Preparation.*
18. *Of ſowing Saintfoine, and managing it while on the Ground.*
19. *Of mowing Saintfoine, and the Uſes of its Hay.*
20. *Of Lucerne; its Soil, and Manner of ſowing.*
21. *Of preparing the Soil for Lucerne.*
22. *Of the Manner of ſowing Lucerne.*
23. *Of the Value of Lucerne, and the Manner of uſing it.*
24. *Of Hop Treſoil.*
25. *Of Ray Graſs.*
26. *Of Spurry.*

The INTRODUCTION.

THE natural Diviſion of the Farm is into Paſture and Tillage, the firſt concerns Graſs, and the other the various Species of Things ſown after Plowing: but though this be generally laſt named, it is by much the moſt important, wherefore we have begun with it, and having in the ſix preceding Books gone through the Conſideration of the Soil, and of its Management various Ways for that Purpoſe, together with the Methods of raiſing the beſt Crops of the ſeveral uſual Kinds; we now come to the other Part which concerns the Graſſes; and after having gone through theſe, which make the ſecond great Conſideration of the Huſbandman, we ſhall deliver the Culture of thoſe Roots which fall in his Way, and of ſeveral Crops of a leſs general Sort.

In treating of the Graſſes, we are led into the Conſideration of two very diſtinct Kinds, tho' from their Uſe blended together; theſe are the Graſs which naturally riſes in the Meadow and Paſture; and thoſe Plants which are ſown in Fields, though from the Purpoſes they ſerve, they are called by the ſame Name.

The firſt Kind may be comprehended under one Term, for its Differences are not great; the other comprehends ſeveral Kinds, Clover, Saintfoine, Lucerne, and others.

The Curious reckon two or three hundred Species or Kinds of common Graſs, but this is a Diſtinction the Huſbandman needs not regard. He will ſee ſome rank and ſome fine, and will diſtinguiſh the Graſs of the low Meadow from that of the up-land Paſture, and both from the ſhort Bite of the Down; and this is all he needs regard.

Theſe ſeveral Species taken together, make what we call common Graſs, or natural Graſs: the others are called artificial Graſſes, a Term we ſhall uſe in Compliance with Cuſtom, tho' not the moſt judicious that might have been choſen.

The natural Graſs is the Produce of our own Country, the Growth of wild Nature, and we have it finer than any other Kingdom in the World: the others are principally of foreign Original; and moſt of them have but newly been brought into Uſe with us.

Natural Graſs will riſe of itſelf, the Wind ſcattering its little Seeds every where, and it is the Covering of our Meadows riſing without Art, or our Aſſiſtance: the artificial Graſſes are to be raiſed by Culture. Land is to be plowed for them as for Crops of Corn, and they are to be ſown with as much Care and Regularity; but, with proper Management, they anſwer the Expence with a very large Return.

We ſhall in that Part of the ſucceeding Book, which treats of the ſeveral Kinds of theſe, lay before the Farmer the Practice of the moſt ingenious, and moſt ſucceſsful in different Places on this Head; and add many Remarks that have not been before made Publick, relating to the Culture of one or two particular Kinds; for there is no Part of the Huſbandman's Profeſſion that more needs to be illuſtrated and explained: but we ſhall lead the Way to this by treating of the common or natural Graſſes firſt, with which every one is acquainted, and wherewith every Farmer muſt have a great deal of Concern.

BOOK VII. PART I.

Of Natural Graſſes.

CHAP. I.

Of the Diviſion of natural Graſs into Meadow and Paſture.

THE Farmer in his Converſation, and Writers in their Books, divide the natural Graſs Grounds into two Kinds, not as differing in the Species, but in the Place of Growth, and the intended Uſe. Theſe they diſtinguiſh by the Names of Meadow and Paſture, and generally underſtand by that Diſtinction, the Graſs intended to be cut for Hay, and that to be eaten on the Ground, but this is an uncertain Manner of ſpeaking. By Meadow ſome expreſs the Graſs of low Grounds only, that lie about Rivers; and by Paſture only ſuch as grows on higher Lands; but both theſe are by the judicious Farmer mowed at Times, and fed at Times, ſo that all that is properly to be underſtood by the two Words is, that being uſed together, they expreſs that Part of the Farmer's Land which is not in Tillage, and they ſhould be uſed together, becauſe this Variation comprehends all Graſs Ground whatſoever, in Diſtinction from all that which is kept in Tilth.

It is a Matter of great Importance to the Farmer, to proportion theſe two Kinds of Ground, the Tillage and Paſturage, one to another. There are many who call themſelves Farmers near LONDON, and about other great Towns, who deal altogether in Paſturage; and this they may do without any Neceſſity of Tillage; but there is no ſuch Thing a Man's keeping his Farm all in Tillage, without Paſture. His Cattle muſt have Food, and his Fields for Corn in the common Way of Huſbandry, require a great deal of Dung for Manure.

This brings on the Neceſſity of keeping up a Proportion between one Kind and the other, for which there is no laying down any general Rule; becauſe, according to the Nature of his Land, and the particular Courſe of Huſbandry he follows, more or leſs Dung may be wanting.

His Experience alone muſt ſhew him this, but he will find it eaſy to make Alterations where it is neceſſary: the laying down a Piece of Corn Land for Graſs, and the taking up a Piece of Graſs Ground for Tilth, being, as we have ſhewn, very eaſy.

There are particular Eſtates alſo that anſwer beſt in various Manners. There are ſome that are ſo rich and proper for Corn, and that lie ſo conveniently for Dung, that a much greater Proportion than the common Method may be kept conveniently and profitably in Tillage; and there are others naturally favourable to Graſs, and that lie where there is a great Demand for it; and in theſe the greater Part ſhould be kept for Paſture.

As we have ſhewn that the Diſtinction into Meadow and Paſture is very little ſettled in its Meaning, we ſhall, to be the better underſtood by all, ſpeak in general of both under the Name of Graſs Ground. The Hay from Graſs Grounds that lie low, and are what is moſt properly called Meadows is generally in larger Quantity than that from ſuch as are higher; but this latter, though there is leſs of it, is ſweeter.

The Abundance of Water that often gets into, or

or upon these low Grounds, makes the Grass rank: and where they lie in the Way of constant Wet, they naturally produce very coarse Kinds of it. We see Rushes grow in barren and wet Places, and there are a great many Kinds of Grass, tho' not enough regarded, that more or less approach to the rushy Kind, which greatly diminish the Value of the Hay, that comes from the wetter Sort of these Grounds.

The Grass Grounds that lie high require Assistances from Manure, but those which are lower, and in the way of flooding, do not; the Overflowing of every River so far imitates that of the NILE, that it always leaves a Mud behind it, which serves in the Place of Manure, and makes the Grass spring fresh, as if Art had been used to recruit the Strength of the Ground.

We have named two Kinds of Grass Grounds, but there is a third yet to be mentioned, which is such as are within the Reach of Salt Water, whether by the Sides of Rivers, near the Sea, or of the Sea itself. These are a great Quantity in one Part or other of the Kingdom, and are capable of being turned to very good Account, their Management therefore is a material Consideration in a Work intended for general Use.

Having premised thus much concerning the Nature and Distinctions of Grass Ground in ENGLAND, we shall first consider the three Sorts separately, and afterwards the general and particular Methods of procuring the richest Produce from each.

CHAP. II.

Of Grass Grounds that lie high.

THESE are what the Farmer generally expresses by the Term up-land Grass Grounds; some by way of Distinction from the lower, call them Pastures, the other having the Name of Meadow. These up-land Grass Grounds differ in Situation as they lie upon higher or lower Risings, or upon their Tops or Sides: they also vary greatly in their Soil, which, tho' it be in general different from that of Meadows, yet is also very various in Kind between one up-land Ground and another.

With Respect to their particular Situation, we must first observe, That as a certain Degree of Exposure is proper for Grass, so there may be too much; and therefore that those Risings which are of a moderate Height, are better for Grass than such as come under the Denomination of high Hills.

The next Difference is, That of their lying on the Top, or on the Side of a Hill; and this is so great, that it often trebles the Value in one above the other: nothing is more frequent than for Ground to be wet and boggy on the Top of a Hill, while it is perfectly fine on the Sides all the Way down.

Springs naturally rise on Hills, and when they are pent in, they break and soak through the very Substance of the Ground, and convert the whole upper Part of the Surface into a Bog.

On the contrary, the Side of a rising Ground that has a gradual Descent, is, of all Situations that can be named, the best for Grass. In such Ground there generally is Moisture at the Bottom, which is very essential to Grass; and there is a Way for it to run off, which is equally necessary.

Grass will not thrive without Water, nor can it be good where there is too much; this is the great Article. Where the Tops of Hills that are any Thing high have no Spring, the Bleakness of the Expofure, and the Poorness of the Soil, as that is commonly the Case, render the Grass very weak: it is sweet, but very little of it; and where there are Springs, it is generally boggy: The Way of getting off the Water we have delivered in a preceding Part of this Work, where we treated of Draining; we here speak of the natural Condition.

Now the Side of a Hill having Soil and Moisture, feeds a rich and good Grass, without having so much wet as to make it rank, or favour the Growth of Rushes, or those other bad Kinds of Mixture, which generally depreciate that which grows on the Tops of Hills, or near Rivers.

As to that in Meadows, lying low, is generally a black rich Mould; and nothing more favours the Growth of fine Grass; but then what these Grounds gain in Soil, they lose by the abundant Moisture.

The up-land Pasture, of which we treat here, have all that Variety of Soils we see in tilled Ground; they are sometimes gravelly, sometimes loamy, at others they are stony, chalky, or clayey. Of all these, the loamy Soil, where there is a good Proportion of rich Earth amongst it, yields the best Grass; upon Clay, it is apt to be coarse, because of the Wet it detains; upon Chalk, it is low; upon Gravel, it is sweet, but thin; the Loam, when of the right Condition, yields it just in the middle Way between all these, it is plentiful yet sweet, and affords the finest Hay, and the sweetest and richest Food for Cattle.

This will direct the Farmer, when he is about to make Changes in the Proportion of his Tillage and Pasture, what to keep for Grass, and what to break up.

The several other Soils will afford good Corn by proper Management, and they are easily dressed when in Tilth; but nothing will answer so well in Grass Ground, as the Soil and Situation we have named.

It may be often adviseable to break up a Piece of Grass Ground that is on a clayey Soil, because the Clay may be improved by the Additions of Sand with great Ease, while in Tilth; but it is not well capable of this while in Pasture. The same may be said of the others: they may be easily made to yield as good Crops of Corn as the Loam, but nothing in this Situation will afford so sweet Grass.

I have observed in LINCOLNSHIRE, that their rising Grounds have often a Soil exactly like that of their low Meadows, a black rich Earth, but, on examining, there is always too much wet at the Bottom; their Grass is, however, much finer than that of the low Grounds. In

many Counties alſo I have obſerved, the Tops of Hills, in general, dry, and their Sides moiſt: in this Caſe the Rule is to be inverted; and it is the Tops that bear the ſweeteſt Graſs.

A Soil that is too clayey, is liable to great Inconveniencies with reſpect to Graſs: in Winter it detains the Wet a long Time, and in Summer it cracks and chaps, and no Earth is more perfectly burnt up.

The black Mould, ſuch as is in the low Grounds, yields Abundance of fine Graſs when it lies dry on the Side of a Hill, but then it is commonly infeſted in a terrible Manner with Worms: the loamy Soils are leſs ſubject to them, and are therefore preferable; ſo that on all Accounts that Preference is due to the rich Loams, which we have given them in Reſpect to the Growth of Graſs: they are not ſubject to poach in Winter, nor to crack or be burnt up in Summer.

Thus let the Farmer judge of the Fitneſs of his Soil for his various Purpoſes, and taking in the whole of the Conſideration, with Reſpect to Graſs, he will now know that a Piece of hanging or ſlanting Ground, with a loamy rich Soil, and a moiſt, but not wet Bottom, is the beſt and fitteſt of all for Paſture; and if he can contrive to bring the Water of ſome Spring occaſionally over it, nothing can add to the Advantage; for ſuch a Piece of Ground, where Water can be ſet on at Pleaſure, and where it will not lodge, is the moſt ſuited by Nature for Graſs of all others. Such a Piece of Graſs Ground as this will require Manure at Times, but it will very well anſwer the Charge, by the Quantity of the Hay, and Richneſs of the Graſs afterwards, for it will always retain its natural Sweetneſs. The poorer the Soil the oftener theſe up-land Graſs Grounds will require Refreſhment, but, in the worſt of them, this is an Expence always returned with Intereſt.

The Manner of enriching theſe Lands by Manures is a ſeparate Article, and we ſhall treat of it in a ſucceeding Chapter.

CHAP. III.

Of Graſs Grounds that lie low.

THESE comprehend what are commonly called Meadows, Fen, and Marſh Lands. All low Ground is ſubject to overflowing, either in a larger Way by Rivers, or in a ſmaller by the Water coming from the higher Grounds in the Winter Rains; and both theſe Wettings are of great Benefit, if proper Care be taken to carry off the redundant Water; and to prevent the Overflowing by Rivers at improper Times.

The fineſt Part of the Mould is waſhed off by Rains from plowed Lands that lie high, and a Part of the Manure with it, and carried down with the Water to the low Graſs Grounds at their Bottom, this it is that renders them ſo fruitful; and in the ſame Manner Land Floods drowning Meadows by River Sides, have the ſame Effect. The Waters of theſe are thick and yellow, with the richeſt Part of the Soil from the adjoining high Grounds, and they leave this upon thoſe Meadows when they lie upon them to ſettle, and are then taken off. This renders the Graſs on theſe Grounds very plentiful, but as there generally remains too much of the Moiſture behind, it is coarſe; there grow Weeds, and ill Kinds of Graſs in them, which are not in the ſweet Paſturage of the up-lands. There is a great deal of Difference in the Value of thoſe Meadows which are liable to be overflowed by Accident, and thoſe which are capable of being overflowed at Pleaſure, but are out of that Danger. In the firſt, the Water may come at a wrong Time, and often does ſo to the utter Loſs of the Crop: but, in the other, it never can come but when it is brought, and yet 'tis at all thoſe Times, when proper, ready at the Huſbandman's Command.

Such Meadows as lie flat on the Banks of great Rivers, are of the firſt Kind: theſe are ſubject to accidental Floodings, which may come at very wrong Times, and are therefore very precarious and uncertain as to the Produce.

Thoſe which lie near leſſer Streams, and a little higher than the Level of their Waters, are of the latter Kind, they may be overflowed when it will do them good by turning the Stream of the Water upon them; and theſe are worth much more than other low Graſs Grounds for this Reaſon; as the others, from their hazardous Situation, are worthleſs.

To thoſe two we may add a third Kind of Graſs Grounds, which are of a Kind of middle Nature between theſe, and the up-land Paſtures. Theſe laſt are ſuch as lie above the Level of the Water conſiderably, yet not ſo much but that it may be brought over them by Means of Wheels or Engines: theſe are expenſive, but the Benefit is very great. We have not the Spirit of the Italians in this Reſpect, nor indeed the Neceſſity: they raiſe Water to a ſurprizing Height for the overflowing their Paſtures; and they owe all their Verdure to that artificial Management.

The Meadows that lie on the Sides of large Rivers, have all the ſame general Soil, which is a rich dark Mould, they yield Abundance of Graſs; and they owe their Fertility to the Overflowings of thoſe Rivers.

Where they can be ſo managed that the Water can be kept out at proper Times, they are very valuable. This we have treated of in a former Part of this Work; but they can rarely be ſecured.

When Graſs Grounds lie near the Borders of great Rivers, but ſo high as not be flooded accidentally, it will always be worth the Farmer's while to have an Engine for overflowing them at ſuch Times as he ſhall think proper.

A very great Quantity of the Graſs Ground in Lincolnshire, and ſome other Counties, is what they call Fen Land. This is of the Nature of theſe flat Grounds, which lie near great Rivers, and are ſubject to accidental Overflowings, but they are of the worſt Kind, being liable to receive vaſt Quantities of Water, and often having alſo Reſources of their own beſide. Theſe we have ſpoken of in a former Part of our Work, treating of the Manner of banking and draining them;

them; as alſo of the third Kind, which are the Salt Marſhes: theſe are in themſelves poor, and full of the worſt Sorts of Weeds, but by Draining and Banking, as we have there ſhewn, they become excellent Paſtures.

Theſe are the ſeveral Kinds, which, having thus laid before the Reader in one View, we ſhall, in the enſuing Chapters, conſider with Reſpect to their Improvement, and moſt beneficial Management.

CHAP. IV.

Of the Accidents to which Graſs Grounds are liable.

WE have ſhewn what is to be expected from each Kind of Graſs Ground, with reſpect to its Soil, its Situation, and its Degree of Moiſture: we now come to conſider thoſe Accidents to which all Graſs Grounds are liable, and which reduce their Value. Theſe are of three principal Kinds, the firſt being from Weeds, the ſecond from Rubbiſh of any Sort, left on the Ground, and the third from Ant-hills and Mole-hills: theſe laſt are the moſt difficult to be removed, but when Mowing is conſidered, they are of all other Annoyances the moſt obnoxious.

Weeds are of various Kinds, and hurtful in different Degrees. All Plants, not of the Graſs Kind, may be called by this Name, when among Graſs, but ſome are beneficial: the white Treſoil, which is a Sort of Clover; and the red Trefoil, which is a wild Clover, are both ſerviceable, and ſo are ſeveral other little Plants that riſe ſpontaneouſly among the Graſs.

The large Weeds are moſt troubleſome, ſuch as Thiſtles, Docks and Mallows. Theſe are to be grubbed up, or drawn with an Inſtrument made for that Purpoſe, called the Thiſtle Hook. This pierces into the Ground, and laying hold of them at ſome Depth, eaſily pulls the whole Root up.

As to accidental Rubbiſh, this muſt always be picked off. Some will be thrown on by Careleſſneſs, and ſome comes on among the Manure; which, though not ſo eaſily ſeen at firſt, is very plainly to be perceived when the Rains have waſhed the rich Part of the Dung into the Ground.

Women or Boys may be ſent in to gather up this Sort of Stuff, which conſiſts of Bones, Bits of Brick, and broken Glaſs; a little Trouble takes it off, and ſaves a great deal of Difficulty to the Mower.

CHAP. V.

Of Ant-hills and Mole-hills.

THE Weeds being drawn, and Rubbiſh picked off, the Ground will remain in a Condition for the Scythe, if there be not Ants or Moles about it; but theſe Creatures will raiſe Hills that will greatly obſtruct the Buſineſs; and that muſt be removed.

There are ſome who pretend, that in feeding Grounds theſe Hills are of Service, at leaſt not of any Damage, but they err in every Reſpect: there never was an Ant-hill that did not occaſion ſome Miſchief, and where there is one there will ſoon be more, for the Ants will ſpread in a little Time over a large Spot of Ground.

The Loſs by them is evident, becauſe they will cover a great deal of Ground; and they bear but a poor Quantity of Graſs. They not only increaſe in Number, but in Size, when let alone, and ſome have them cut up at laſt that would half fill a Cart. They make the Ground diſagreeable to the Eye, and very unpleaſing to Cattle that feed on it, and have all theſe Inconveniencies yearly increaſing. The prudent Huſbandman weighing this whole Matter, will not follow the Example of thoſe, whoſe Lazyneſs or Ignorance ſuffer them to ſtand, but will reſolve to extirpate them at once, the ſooner he ſets about it the leſs is the Expence; and tho' it grow greater as theſe Hills are more numerous or large, he ſhould not be diſheartened by that, but aſſure himſelf, that the Advantage will be many Times greater than the Charge.

There are ſeveral Methods of deſtroying theſe Hills, and we ſhall give the Huſbandman his Choice of them; but when there is any Quantity of this Work to be done, he will find the Plow we ſhall recommend for that Purpoſe, vaſtly the beſt.

Some order their Servants into the Graſs Grounds in Spring, to cut up theſe Hills by Hand; and where there are not many of them, this may anſwer: it is to be done thus. A thin Shovel is to be made for the Purpoſe, and well edged with Iron; with this the Workman is firſt to cut down through the Ant-hill, beginning at its Top, and preſſing the Shovel down with his Foot: he is then to draw it out, and make another croſs Cut: this ſeparates the Turf and upper Part of the Hill into four Quarters, then are to be thrown back, and then the Earth underneath is to be dug up with the Neſt of the Ants among it. This being done, the four Quarters of the Turf are to be thrown together again, and they will ſoon cloſe and grow.

This is now a Method in ſome Places, and was at one Time practiſed univerſally; but the Diſadvantages attending it are plain: in the firſt Place, here is a diſagreeable Hollow left in the Ground; and then, doubtleſs, ſome of the Ants will remain in the Turf; and having ſo good an Opportunity, they will ſoon multiply, and get to work again; and the Hill will be as big as ever in a little Time: for they are covered by the Turf from the two Accidents moſt pernicious to them, Birds, and ſevere Weather.

But there is another Conſideration behind; which is, the Body of the Ants, with the Earth taken out of the Hole. How to diſpoſe of theſe is no little Difficulty. The old Cuſtom was to break the Clod to Pieces, and ſpread it over the Surface of the Paſture; but this was not deſtroying the Ants, it was only diſperſing them: there was nothing to prevent their getting together again, and accordingly they ſoon did ſo, and the Field was over-run with them.

At preſent the Farmers about London dig them out, and carry them off to their Dunghills, where ſome are deſtroyed, but ſome remain alive, enough to renew the Miſchief. Theſe Hills mix among the Dung, and they are carried with it again upon the Ground, where they breed, multiply, and renew the Miſchief.

One wonders that People who found ſo much Inconveniencies from theſe little Inſects, could content themſelves with ſuch imperfect Methods of remedying it; but ſuch were the beſt known for a long Time, and ſuch are in many Places the only Ways yet uſed.

There cannot be too much Care in the utterly extirpating theſe Creatures, nor in a proper Method of ſetting about it can there be any Difficulty. An excellent Inſtrument for this Purpoſe is the Ant-hill Plow, figured in our ſucceeding Plate; its Structure will be underſtood by any tolerable Workman from the Figure, and we need only caution the Huſbandman, that it be made ſtrong in Proportion to the Service. The Timber Part muſt be Elm or Aſh, and its two Sides about five Inches ſquare; the Iron Part muſt be made thick enough, and be well ſteeled; and it is to be drawn by two or more Horſes lengthwiſe.

This being properly guided, will cut through any Depth of Earth in theſe Hills, and taking them off entire, they may be eaſily removed, and the Surface will be left perfectly even.

When the Edge of the Iron wears, it muſt be carefully repaired, and the Implement always kept in good Order. The Advantage is very great above any other Method, for the few Ants that are left in the Ground, are expoſed to all Kinds of Injuries, and are ſeldom known to be much troubleſome again; and the ſmooth naked Surface being immediately ſown with Hay Seed, preſently becomes uniform with the reſt of the Ground.

The Expence is little, for a tolerable one may be made for a Couple of Guineas, and a very good one, fit for any Service, for Half a Guinea more; and the Price will be ſoon ſaved by the Quantity of Buſineſs done: as many Hills may be cut down with this in a Day, as would take ten or a dozen Labourers a Week.

The Perſon who guides this Plow, will make it cut deeper or ſhallower as he pleaſes, by raiſing or lowering the Handles; and there is nothing it will not make its Way through, with a good Hand to guide, and a proper Force to draw it.

The Buſineſs of the Perſon who guides it is to cut all ſmooth and level with the reſt of the Surface. The Hills being thus cut up, there remains the Care of diſpoſing of them ſo, that they ſhall not afford a Return of the Miſchief. Many Ways have been deviſed for this Purpoſe. It is evident the common Methods of ſpreading them on the Ground, or carrying them to the Dunghill, are extreamly wrong: but we ſhall ſhew the Farmer how he may at the ſame Time be ſure thoroughly to be rid of the Danger of their renewing the Miſchief, and at the ſame Time make an Advantage of them.

In the Uſe of this Plow we have ſaid the bare Space made by cutting up the Hill, is to be ſown immediately; for that Reaſon a Perſon is always to follow the Plow with a Parcel of good Hay Seed in his Pocket; and while he carefully ſows this on the bare Spot, others are to follow and take Care of the Subſtance of the Hills.

Theſe are to lay them in Heaps, which are to be made with Care, not very broad at the Bottom, but high and hollow; and when they have ſtood a little to dry, they muſt be ſet on Fire, and burnt to Aſhes, in the Method we have ſhewn in the Article of burning the Baite.

Where there are but few of the Hills, they may be eaſily piled up in the ſeveral Corners, and waſte Places, and burnt upon the Spot, (which is much the beſt Way) without damaging the Ground; but where there are a great many, as in Places where the Ground is over-run with them, they muſt be carted off the Spot, and burnt in ſome waſte Place, the nearer the better, for the Convenience of carrying back the Aſhes; for, in both Caſes, the Aſhes muſt be carried over the Ground, and ſpread carefully, and they will ſerve as an excellent Manure.

We have obſerved that up-land Paſtures require now and then to be refreſhed with ſome Dreſſing, there is none better than theſe Aſhes; and 'tis in thoſe Paſtures, where they are moſt wanted, that the Hills are moſt frequent. In this Caſe the Graſs will grow every where with an Aſpect of Strength and Freſhneſs; and that on the Places where the Hills ſtood, will ſoon equal the reſt.

There are other Methods of uſing theſe Hills, when they are cut up to Advantage, as a Manure; and the Farmer, according to his Diſcretion, may uſe one or the other. He will find in our Chapters on Manures, which Kind of Dreſſing will be beſt for his Graſs Ground, according to its Situation, and other Accidents; and let him prefer ſuch of the ſeveral we here propoſe to be made from the Hills, as will beſt agree with its Nature.

We have mentioned the burning them to Aſhes, which, on many Occaſions, is the beſt and readieſt Method. A ſecond Way is to carry them all off the Ground, and lay them together to rot perfectly. The Ants will be thus better prevented from a Return, than by throwing in the Hills among a common Dunghill; for, in that Caſe, they ramble about the Heap, ſome Parts of which are dry enough for their Reception: and as it is ſoon carried on to the Ground again, many of them remain there till they go with it, and then increaſe, and make new Hills; but, on the contrary, when the Hills are thrown into a Heap to rot alone, they become very moiſt throughout, ſo that there is no Place for the Ants to live among them, they muſt either leave the Matter, or be ſmothered among it: one Way or other the Ground being cleared of them, and the Manure alſo: there will be no Danger from its going on again. This rotting of the Turf takes Time, and by that Time it is ready for ſpreading, the whole Race of theſe little Vermin will be utterly deſtroyed. It may then be ſpread over the Ground without Danger, and will prove an excellent Method of refreſhing it for a new Crop.

A third Way is to uſe the Hills entire, as they

they are cut up in Compoſt. The Reader will recollect, that we have recommended the Uſe of a covered Pit for Dung, and other Ingredients, to make Compoſt, and have given a Figure to explain its Structure.

Into ſuch a Pit the whole Hills may be thrown among the Mud of Ditches, freſh Horſe Dung, and the Drainings of the Cow Houſe and Stables; here all is kept ſo moiſt, and in ſuch a State of Fermentation, that it is impoſſible an Ant can live, or any Principle of Life can remain in what are called the Eggs, during the Time of the whole remaining there together: therefore the Addition in Point of Quantity, will be very great, and the whole may be uſed equally for the plowed Land and Graſs Ground, without the leaſt Danger from the Ants in either.

What are called Ants Eggs are the Caſes in which thoſe Creatures remain a Time in Quiet, before their Perfection in the winged State. Reaſon ſhews they cannot be Eggs, becauſe they are bigger than the Bodies which are ſuppoſed to have laid them; and we ſee Bees, Flies, Butterflies, and all other Creatures that have Wings, go through a State of Reſt in this Manner, before they attain their perfect Form.

A fourth Way of uſing theſe Ant-hills with Safety, and to the Advantage of the Ground, is to make them into a Kind of dry Compoſt with Lime, and other Things: this is a very ſafe Method, and is more expeditious than the other: but the Farmer by this Time well knows that different Grounds require various Manures; and he will therefore take whichſoever of theſe Methods beſt ſuits the Nature of his particular Paſture.

The Method of uſing it in Form of the dry Compoſt is this. When the Hills are cut up by the Plow, and carried out of the Field, they are to be thrown on a Heap in ſome waſte Place; and a Quantity of freſh and ſharp Lime being in Readineſs, it is to be ſtrewed pretty thick among them; and ſo managed, as to reach every Part of them.

To this Purpoſe the beſt Method is to ſpread a Parcel of the Ant-hills on the Ground as thick as they can lie, without covering one another; and on theſe to ſtrew a good Quantity of Lime: then to lay over this another Coat of the Ant-hills, and then another ſcattering of Lime, and ſo on, till all the Hills are piled up.

In this Manner let the whole remain ten Days or a Fortnight, and in that Time the Lime will have taken ſo good Effect, that there will not be an Ant found in the Place. Then let a Quantity of good freſh Dung be laid on the Heap, and from time to time let it be well worked and turned as other Dung is. This Compoſt may be laid upon the Ground from which the Hills were taken, and there will not be the leaſt Danger of their propagating again; and the Benefit, in a tolerable good up-land Paſture, will laſt ſix Years. This I have found by Experience; nor do I know any Manure ſo good, on a proper Soil, as this Mixture of Dung, Lime, and Earth, for Graſs Grounds. The Bodies of the Ants, which are very numerous in the Hills, will alſo, in this Caſe, add a great deal to the Efficacy; for we have ſhewn before, that all Animal Subſtances are full of rich Matter for the Service of Vegetation. This Mixture of Dung and Lime with Pond Mud, is excellent by way of Manure for Graſs Ground; but when the Earth that is uſed for this Purpoſe is thus impregnated with Animal Matter, by being the Reſidence of Millions of theſe Inſects, and full of their Excrements, the Benefit is vaſtly greater.

When the Farmer ſees the Practice of cutting up Ant-hills thus in its full Light, he will be able to count up the Gains riſing from a proper Uſe of the Inſtrument by which it is to be performed, and he will find that in a Courſe of ſix Years Growth of Graſs, the Expence of the Inſtrument, the Labour, and every Thing that can be brought into the Account, will be above forty Times returned to him; and all the while he will have his Paſture lie in a Manner agreeable to his Eye, in a proper Condition for the Mowers, and for the Cattle.

Among the Accidents to which Graſs Grounds are liable, the lodging of Water upon them might be enumerated; and, indeed, as the principal; but that we have treated of already, under the Article of Draining; therefore having gone through the Account of Things which may hurt the Farmer in this Reſpect, we ſhall now proceed to the Improvement of this Part of his Farm, by removing the greater Annoyances, and enriching the Soil.

CHAP. VI.

Of clearing a Paſture Ground from Stumps and Buſhes.

THE Way of drawing Thiſtles, Docks, and the like large Weeds by their Roots, has been laid down among the other Methods of improving a Graſs Ground, by removing the Accidents that hurt it; but we are here to conſider a much greater Annoyance, which is, the frequent Growth of buſhy Stumps, and unprofitable Shrubs. Theſe are not uncommon in many up-land Paſtures, and they are ſuffered in the ſame Manner as Ant-hills, to remain upon the Ground by the Idleneſs or Careleſſneſs of the Farmer, till they reduce the Paſture to the half or third Part of its Value.

I ſhall here ſpeak of what I have very lately ſeen practiſed, partly by many of my own Advice, and partly by the Spirit and Reſolution of the Owner; by which about eighteen Acres of up-land Paſture, have in five Years been rendered of four Times their former Value.

This Paſture was one of thoſe up-land Pieces, of which there are many in Buckinghamshire, and moſt other Counties where the Graſs is but little in Quantity, but very ſweet; and the Ground is over-run in Patches with Broom, Furzes, and Butchers Broom.

Walking with the Owner of this Piece of Ground, who kept it in his own Hands becauſe no-body would give him any Price for it worth naming, I propoſed to him to undertake its

Improve-

Improvement. This I told him muſt be ſet about by two Methods at once; the one was, the getting up all theſe Shrubs, and the other, laying on a good deal of rich Manure. Few would have had the Spirit to venture ſo much as he did on this Advice, upon ſo barren a Piece of Ground; but three Years Profit amply returned it to him, and now every Farmer in the Neighbourhood is deſirous of renting the Field. The Method he took for clearing it was this. He had, according to my Directions, an Inſtrument made for tearing all the Shrubs up by their Roots; which, from its Uſe, I ſhall take the Liberty to call an Eradicator. The Invention is not mine, but as old as the Time of Gabriel Plat, who has mentioned it in his Diſcovery of hidden Treaſures.

It is a very large and ſtrong three-pronged Fork, which, by the Aſſiſtance of a Block, as a Leaver, is of ſufficient Force to tear up any Thing. The Bigneſs of it is ſo much more than a Dung Fork, which it moſt reſembles, that it ſeems improper to call it by ſuch a Name, wherefore I have given it another. It is to be thus conſtructed. The Handle muſt be a long and thick Beam of Aſh, its Length fifteen or ſixteen Foot, and its Thickneſs ſuch as will keep it firm againſt a great deal of Force. The Tines ſhould be twenty Inches long, notched at the Sides, and a little leaning upwards; and they muſt be joined to a ſtrong Shoulder of Iron, with proper Faſtenings, for the End of the Pole. This being carefully fixed on, the Perſon that works it muſt faſten a Rope of ſix or eight Foot long to the other End, and take with him a thick Block of Wood, and a heavy wooden Beetle.

When he comes to the firſt Shrub of Broom, Furze, or whatſoever; he muſt force in the three Points ſlanting into the Ground, ſo that they go under the Root, and the Top of the Pole be ſomewhat higher than his Head: then with good Strokes of the Beetle, he muſt drive it well in, till the Tines are quite in the Ground: he is then to lay the Block under the Pole, near where the Tines are, this will raiſe its Top ten or twelve Foot high; and he is then to lay hold of the Rope, and pull with all his Force.

Thoſe who know what the Effect of the Lever is, will be ſenſible no Root can keep its Place againſt this: it will tear up the moſt firm; and, in ſome Kinds, will draw out Fibres of ſeven Foot in Length.

When one is up, he is to proceed to the next, and ſo through the Field; throwing them on Heaps as they come up, that they may be ready for carrying off the Ground.

The Field I have been ſpeaking of when we begun this Work, was ſo full of Tufts of Shrubs, that there was not ten Yards of it that could have been mowed, if the Produce had been worth it; and it was very inconvenient even to feeding.

If we had employed Men to grub them up with Pick-axes, as is the common Way, it would have coſt at leaſt twenty Times the Price; and the Ground would have been tore up in a ſad Manner; and when we had done, ſo many of the broken Roots would have remained, that there would have been preſently a new Parcel of Shrubs upon the Ground; whereas in this Way, the Expence was little or nothing: the Price of the Inſtrument no great Matter, and it will laſt for ever; and the whole Charge of working it, a Couple of Labourers Wages for the few Days that was neceſſary. The Ground was no where broken to ſignify; the Roots, in this Manner of drawing, only cracking the Turf, which fell together as ſoon as they were out; and the biggeſt not ſo much as diſtinguiſhing the Ground for a Foot ſpace, and that moſtly made up again by the falling of the Surface together.

When the Ground was thus cleared, we got together a large Quantity of Manure made of old well rotted Dung, and the Mud of the River; among this we mixed the Bottoms of a Couple of old Hay-ſtacks, which was a rich rotten Earth, full of Graſs Seeds. This being ſpread thick upon the Ground, and waſhed in with the next Rains, the Effect was in a Manner miraculous; from a miſerable barren Place, it became the next Spring very fine Paſture, and is now a prime Piece. The Roots of the old Graſs ſhot freely, having no longer the woody Fibres of the Stumps to intangle with them, and hinder their Progreſs; and the Seeds moſt of it grew ſo, that here was Abundance of Nouriſhment, and a great Number of Plants to draw it.

This is to be done in any Place in the ſame Manner, and the Advantage will be the ſame. Plot might very well call the Secrets of Huſbandry a hidden Treaſure, for we ſee ſuch of them as he diſcovered expoſed to view; nay, ſuch as the moſt common and popular Writers copied from him, and inſerted in their Books one after another, yet remain unknown or unheeded by the Farmer, who might ſo greatly add to his Profits by their Uſe. This is an Inſtrument no Farmer ought to be without, who has any of this poor, and over-run Paſture Ground upon his Hands; and, by a propet Uſe of it, I am convinced by what I ſaw on this Occaſion, that a great deal of what lies nearly as waſte Ground in this Kingdom, might be made to bear a Price. The beſt Time for doing this is after Harveſt. The Ground will then have Winter to be quiet; and, in Spring, the Shoot will be ſeen ſtrong and fine.

CHAP. VII.

Of improving moſſy Paſture Ground by burning.

IN the laſt Chapter we treated of the Methods of improving Paſture or Graſs Grounds, when over-run with uſeleſs Shrubs: we are here to conſider another Annoyance; which, though leſs conſpicuous, is as pernicious in the Effect; this is, the ſpreading of Moſs, or other low and worthleſs Matter among the proper Growth.

Moſs is a ſculking Enemy to the Farmer in his

his Pasture Grounds, but a very fatal one; the Grass where this is predominant will appear low and thin, and the Cause at first perhaps will scarce be seen, but on examining there will be found, as it were, a Carpet of yellowish Moss spread over the Surface of the Ground, through which the few Blades of Grass have Difficulty to make their Way: as this continues the Mischief encreases, for the Moss sending out its Side Branches and young Shoots, thickens more and more, covers the Earth with a deeper and more compact Coat, and makes the Growth of any thing else more and more difficult among it.

This is commonly the Fault of Ground that is too damp.

In the same Kind of Land, when a little wetter than this, we see Tufts of Rushes, or of what though less conspicuous, is as mischievous, a low Kind of Rush Grass; this grows in thick Sods and covers a great Part of the Ground, nothing grows among it, and not much between it. The Sods spread and encrease from time to time, till at length they will overspread the whole Piece.

These, as they are the Faults of the same Kind of Ground, require the same Kind of Remedy; and what we shall advise in this Case, though a very expensive one, yet is so certain of Success, and the Misfortune so incapable of being remedied any Way else, when grown to an Heighth, that it will always answer, and always be found more advantageous than the cheaper and more imperfect Methods. What Grass there does grow on these Grounds is small in Quantity, short, and poor. In dry Pastures the Grass is frequently short, but it is sweet; and where there is little of it, that little is good; but here it is quite otherwise, what poor Growth there is, is sour, and Cattle neither like it nor thrive upon it.

The Way to remedy the Evil is by burning the Rubbish with some small Parings of the Surface, and sowing a better Crop.

To this Purpose the Turf is to be pared up in the same Manner as we have described for Burn-baiting, and to be set up on Heaps, and when dry to be fired.

It is a Sort of Stuff that will take Fire readily, and will presently burn out. The Ashes will be a very rich Manure, and the Roots of the Moss, and other mischievous Matter will be perfectly destroyed.

The best Time for doing this is in the Beginning of October. When the Heaps are reduced to Ashes, these are to be spread upon the bare Surface and plowed in. The whole must be then sowed thick with Hay Seed, and the Event left to Nature. There will soon be a short Green Covering upon the Surface; and this, as it makes no great Shoot upwards during the Winter, will be all that Time strengthening itself about the Root. It will thus get into Tufts, and entangle and mat the Fibres together during the Winter, and in Spring it will shoot up, and be a very pretty Pasture.

At the same Time that this is done there should be Drains cut through it in two or three Places, to carry off the Water that occasioned the Dampness, and thus the Owner will indeed have a Right to expect a new Kind of Produce, for he will have a Sort of new Land.

In the Choice of the Seed for this Service, there is to be great Care taken it come from Hay that had grown on Land not altogether unlike this, in Respect of Moisture.

We have observed before, that the Botanists reckon up a great Number of Kinds of Grass, and have told the Farmer he needs not concern himself about their Distinctions: this is all he need regard, that as some Grass Grounds are moist, and some dry, there are certain Kinds of Grass that grow on the one, and certain other Kinds on the other; and that he is to suit his Seed so far to his Ground, for that the Seed of the Grasses that delight most in wet Grounds will not succeed on such as is dry; and in the same Manner the Seeds of Grass from upland Pastures will, in a great Measure, miscarry in Meadows. Therefore when Hay Seed is taken for the Purpose of sowing this new recovered Land, it must be got from such Hay as has grown on Meadows in low Places, not that of upland Pastures. This will strike freely and spread properly, so that there will be no Danger of a good Harvest of Hay the very first Year; and from that Time the Ground will continue encreasing till the third; after which, if no farther Care were taken, it would decline; but when the Husbandman is informed of this, he must take Precautions accordingly.

We have had Occasion, in a former Part of this Work, to observe, that the Effect of burning the Surface is very great for the Time, and lasts some few Years, but afterwards leaves it worse than it was; this which we there shewed to be the Case, with Respect to Corn on burnt Land, is much the same with Grass, only less in the Extream both Ways. The Fertility is not so surprizingly great, neither is the Effect so bad afterwards.

However, as in this Case the Ground will grow weak after three Years, Care must be taken to renew it by proper Manures before that Time; and the best for this Purpose are those which are most lasting in their Effects.

If there be a proper Kind of Marle in the Neighbourhood, a good Quantity of that should be laid on at the End of two Years, taking Advantage of a dripping Time in October. The finest Part of the Marle will so be washed into the Ground at once; and the harder Lumps will break with the Frost, and then their Substance will wash in after the same Manner.

When there is no Marle, Pond Mud is the best Manure; but this never succeeds so well on these Occasions, as when it is mix'd with rotten Dung, and the Bottoms of old Hay Stacks.

These Methods will keep the Ground in Heart. And the Person who has recovered it for himself, will leave it in the same Condition to his Descendants.

CHAP. VIII.

Of improving common Graſs Ground by Manures.

DUNG is an univerſal Manure for Graſs Ground, and the more mellow and rotten it is, the better: moſt People content themſelves with it, and ſeek no farther, but we have ſaid before, that Graſs Ground being of different Soils as well as Corn Land, admits with Advantage the ſame Diverſity of Manures. We ſhall here conſider them in a ſhort Compaſs, having entered at large upon their ſeveral Natures before.

For Graſs Ground of the common Kind, where the Soil is a fat Loam, or a Loam with a very large Quantity of mellow Earth among it, the beſt of all Manure is what we have already named, old Dung and Pond Mud mixed together. This may be conſidered as the general Manure for theſe Grounds; and the Time of laying it on is according to the particular Circumſtances or Uſe the Farmer makes of his Land, from September to February.

The moſt favourable Time of all is in the Middle of Winter, that there may be Froſt to diſſolve and break to Pieces the harder Parts of the Manure, and the Rains may waſh the whole into the Ground at their Leiſure, while there is no great Power of Sun to evaporate the Virtue of it as it lies ſpread on the Ground.

The Way of laying on Manure upon Graſs Ground, is to drop it in ſmall Heaps at due Diſtance; and firſt employing Labourers to break and ſpread it well by Hand, the Owner is afterwards to have it worked over with a Buſh Harrow, which we have deſcribed in a former Part of this Work, but have figured in the ſucceeding Plate, among the other Implements uſed in the Graſs Field.

This Harrow is to be lightly drawn to and fro over the Ground, till the whole Quantity of the Manure be thus torn to Pieces, and ſpread over the Place; it will then be ſoon buried among the riſing Shoots of the Graſs, which will grow up apace from the Effect of its enriching Quality, and what remains will have Time to get thoroughly well into the Ground.

This we have laid down once in the Uſe of the common Manure for a moderate Soil, and ſhall not repeat it as to the others: whatever Dreſſing we order to be laid on Graſs Grounds, this, ſo far as its Nature allows, is the Manner of ſpreading it.

When a Piece of Graſs Ground produces Moſs, and other bad Things, but not in ſuch a Degree as to require the Method of cutting up and burning, the beſt Method is to ſtrew over it twice a Year, namely, in October and in the Beginning of February, a Mixture of two Parts Coal Aſhes and one Part Wood Aſhes, wetted with the emptying the Pots of the Family.

On a Piece of Graſs Ground that is cold, but not very wet, let the Huſbandman ſpread a good Dreſſing of Pigeon's Dung; or of the Dung of Fowls mixed with Earth and Coal Aſhes. This is to be done at the latter End of February, and being the richeſt of all Manures it muſt be ſpread with the greateſt Care and Attention; it will thus come to the Roots of the Graſs, juſt as they are about to make their Shoot, and will cauſe twenty Blades in many Places to grow for one.

There are good Graſs Grounds on the Sort of Soil quite oppoſite to what we have been naming, that is, on ſuch a Loam as having a great Proportion of Sand, and little of the binding Ingredients in it, is hot, looſe, and crumbly. In this Caſe the Manure muſt be varied as the Soil varies; and of all that can be recommended, nothing comes near the Virtue of any one of thoſe clayey Marles we have deſcribed under the Head of Manures; a Dreſſing like this laid on early in Winter, becomes quite broken and mouldered by the Spring, and will all waſh into the Earth, the Conſequence is that it gives the two Qualities wanting Firmneſs and Fatneſs. The Quantity of Hay may very well be doubled by ſuch a Dreſſing, and the Feeding in Proportion; and although this be an expenſive Manure for Graſs Lands in the firſt laying on, yet it very well anſwers in the End; for the Effect, inſtead of three or four, which is the common Duration of Manures, will laſt ten or twelve Years.

There is a hungry, cold, brown Soil, not uncommon in Paſtures, conſiſting of ſome poor loamy Earth, and a little Gravel. On this no Manure anſwers like Chalk: but then it muſt be a proper Kind, otherwiſe there will be Damage inſtead of an Advantage.

There is Chalk as hard as a Stone, and there are other Kinds as ſoft as Butter. If the firſt ſhould be uſed it would lie like ſo much Rubbiſh on the Surface, and cover one half of the Ground without doing any Good to the other: but if the latter or ſoft Kind of Chalk be choſen, it breaks and diſſolves with the Weather, and waſhes in entirely. November is the proper Seaſon for laying on ſuch a Manure, and the Froſts acting on it firſt, and afterwards the Rains, it will all work in ſo perfectly, that by Lady Day there ſhall not be a Lump as big as a Nut any where ſeen upon the Ground.

In ſome of the up-land Paſtures in Derbyshire and Staffordshire, there is a Kind of brown Earth full of Fragments of Stone. The proper Manure for this is Lime: we have ſhewn in the treating of Corn Land, what a vaſt Effect this Subſtance takes in ſweetening and fertiliſing Land; and it has altogether the ſame in Paſture as in plowed Grounds.

When a Graſs Ground is very ſandy, the Crop muſt of Neceſſity be very thin, but the Graſs will be ſweet: in this Caſe, if there be in the Neighbourhood a ſoft Clay, with a ſmall Mixture of Sand among it, this ſerves as an excellent Manure; for the Sand in the Compoſition will make it break and moulder, which Clay alone would not, and thus it will waſh into the Ground. Thus it will give Firmneſs and a Body to the Soil, which is all this Kind wants, and as to the ſmall Quantity of Sand that gets in along with it, that is only added to the general Maſs, and can do no Harm.

These are the several Manures that succeed best on the various Kinds of Grass Grounds; and the Farmer sees the Soil to which they are suited, and what are the best Times of laying them on. We need only give him this Caution with Respect to them all, that the Expence of them should never deter him from their Use, for that the very dearest always bring a manifold Return.

CHAP. IX.

Of the general Management of Grass Ground.

THE two Purposes to be answered by Grass Ground, whether Meadow or Pasture, are the feeding Cattle at certain Seasons of the Year, and the affording Hay at others: the Farmer is to have both in his Eye, and to consider their several Benefits, that he may know where to borrow from one, for the Advantage of the other, when he knows the Profit will be answerable.

The first Consideration is of the Time for feeding, and the Time for laying up for Hay. This varies greatly in different Parts of the Kingdom. The different Situation and Condition of the Ground makes some Variation on this Head very natural and very necessary; and the Circumstances of the Farmer, with Respect to the Necessity of feeding, must in some Instances be allowed to break in upon what is known to be more right.

In Places where they have Plenty of Manure, and make two Crops of Hay, the Custom generally is to lay the Ground for it about the Middle of February. And in this Case a little more than three Months gives it a Growth for cutting; so that there is Hay by the Middle of May: in other Places they are five Weeks later in laying them for Hay, and the latter End of March is a common Time.

In the Northern Parts of England I have observed they are as backward in their Hay-making, as their Corn Harvest, and they lay their Grass Lands for Hay accordingly. May Day is, in these Places not an uncommon Time.

There is nothing so wrong in the Husbandman's whole Practice, as the defering the laying his Ground for Hay so long: it may be convenient to him to feed upon it; but let him consider what will be the Effect of a hot dry Summer, and what will be the Loss if he be disappointed of his Crop. Spring is the Season for the Grass to make its Shoot; and if it be eaten over and over again at that Time, and hot dry Weather follow, it is deprived of the Benefit of Rains, and never makes that first Shoot tolerably, nor comes to any reasonable Growth afterwards. For these Reasons let the Farmer suit his several Occasions so, as to be sure of laying down his Ground for the Hay in Time; and if he lose something in the Advantage of feeding, he may be perfectly assured of making himself ten-fold Returns for it, in this more profitable Article. We shall begin the Management of Grass Grounds with the Preparation for laying them down, and from thence date the Beginning of the Farmer's Care.

We will suppose him in the Middle of March, to take off his Cattle from the Grounds where he has good Expectation of Hay, and to prepare for it by making all clean and even.

As soon as the Cattle are off let him send in Women or Children to finish the clearing of the Ground, by picking up the broken Boughs of Trees that the Winter Winds may have thrown in upon the Grass, and every other Kind of Annoyance: this done let him send in a Labourer or more, according to the Compass of Ground, and let these have Orders to break and spread all about, the Dung that may have fallen from the Cattle upon it; and also to break and scatter any fresh Mole-hills.

This being done, the Expence of which is very little, and the Convenience and Benefit very great, let him order the Ground to be rolled carefully and thoroughly.

The rolling Grass Grounds intended for mowing is of great Consequence, as it prepares the Surface for the Scythe, and destroys the last Accidents that can happen to it during the Preparation for Hay.

In the Winter Months the Surface of the Ground will be rendered here and there unequal, by the treading of Cattle, in such Places as the wet has most affected, and where it has lodged most: these make the Growth of the Grass so far irregular, and therefore are an Injury.

During the first Approach of Spring the Worms will be at Work, and will every damp and mild Night throw up Abundance of their Casts; these also are like the other, Nuisances, though not great ones, and they hinder the right and regular Growth of the Grass: if there be Moles, or if there be any Ants left, they will also be at Work at the same Time; and this is a Season at which all should be set right; and the Condition of the Ground is such that it will easily be so. The Roller will answer the Purpose, for it will take more Effect at this Time than at any other.

The Winter's Frosts will have mellowed all these broken Parts of the Ground, and the Spring Rains will have softened them, so that the Roller will take full Effect upon them. The Rubbish of all Kinds has been taken off, and all the old Unevennesses taken down, so that there can be nothing in the Way hard or different from the general Surface; therefore the Roller will break and crush all the little Irregularities there are, and laying the Surface perfectly even, will make Way first for a regular Growth of the Grass, and next for the easy cutting of it.

The Roller is to be of Wood, but it must be made as true and even in all its Surface, as if cut out of Stone, or cast in Iron. In general, the heavier it is the better; therefore it should be large. The Trunk of a good sound thick Elm makes the best Roller; but the lower Part must be cut away to a Truth, and none of the Bark should be left on the other.

We have shewn the Farmer how he is to cut up his Ant-hills. But this is a Practice that will, in a great Measure, prevent the Expence and Trouble of that Article. The Spring is the principal Time when these little Vermin are at work;

work, and if they be prevented then, they will, in a great Measure, lie ſtill till that Time twelve Month. The rolling with a Roller of proper Weight, cruſhes down and deſtroys their new Work, and kills a great many of them; after which the reſt ſcatter ſo, that there ſeldom is any Miſchief.

There is a farther Uſe in the Rolling of Graſs Ground, of which few are ſenſible; and this is, the preſſing down the Earth about the Roots of the Graſs, and by that Means ſecuring the young Shoots, on which a great Part of the Hay depends, from Accidents by the Variety of the Weather.

We ſee in Gardening that Froſts are moſt fatal to Plants, when the Spring has been ſome Time advanced: the Heat of the Weather making the ſucceeding Cold of the Nights more hurtful. It is the ſame in Reſpect of this young Graſs, and this preſſing down of the Earth prevents it.

In the ſucceeding Months alſo, if there do not fall Rain, the Sun parches up the Roots if the Earth be left looſe about them; but when it is thus preſſed down, they are defended.

This preſſing together of the Earth about the Roots, has alſo another Effect of great Conſequence, in preventing the Lodging of the Graſs: this Accident, which is as miſchievous in a Manner to Graſs as to Corn, happens principally from the Looſeneſs of the Earth about their Roots. When the Graſs of the Corn has ſome Height, the Wind will take Effect upon it, and bear it down; but then if it be well ſupported at the Bottom, it riſes again as ſoon as the Blaſt is over, and there is no Harm done: the Wind rarely breaks the Stalk of Corn, and more ſeldom that of Graſs; ſo that unleſs their Support fails them at the Root, they riſe again. When the Earth is looſe it gives Way, and being preſſed down, they remain down; but when it is firm about their Bottom, no Harm happens: Rolling always gives it this Firmneſs, and therefore prevents that Accident.

When the Roller is brought on the Ground, a careful Perſon is to be employed in managing of it; and it muſt be drawn equally, and ſlowly along. The firſt Care is, that it go over every Part of the Ground; and the next is, that it be drawn leiſurely, for otherwiſe it will not do half its Buſineſs. Whoever will watch the Paſſage of a Garden Roller, over a Gravel Walk when it is a little wet and rough, will ſee plainly this Difference: the ſame Roller, when drawn haſtily over the Walk, ſhall take very little Effect; which, being drawn over it carefully, and ſlowly, will make all level.

In this Manner the Roller is to be drawn over the Paſture or Graſs Ground intended for Hay; and when this has been done, the Farmer has nothing more to do, but to ſee his Fences are ſecure, and leave the Growth to Nature; the Shoots will be numerous and firm, and there will grow a large, and every Way excellent Crop. In low Grounds the Cattle may be ſuffered to feed ſomewhat longer than in the up-lands, unleſs the Seaſon be very wet; ſo that it is ſome Relief to the Farmer. Though he ſhould lay his higher Grounds at the Time we have directed, he will have, in a tolerable Spring, a Fortnight or three Weeks; and, in a very dry one, a Month more for his low Grounds.

In theſe, as well as the others, when they are laid for Hay, let him take Care to have the Ground levelled, and all Rubbiſh picked off; for, when the Mowers come to work, all that Charge will be very well returned. There will be none of thoſe Stops and Stayings that there are, and always muſt be when there are Hillocks, and other Impediments in the Way; and the Mowers will be able not only to go on with their Work regularly, but to come an Inch or two cloſer to the Ground; and this is a very great Concern. The Farmers have a very juſt Obſervation, that one Inch of Hay at the Bottom is worth three at the Top, and they have Reaſon: nor is the Aftermath at all the worſe for this cloſe Cutting. That does not depend upon the Stumps of the old Graſs that are left, but upon the new Shoots made from the Root; and the cloſer thoſe are cut, the more free that Shoot comes, ſo that the cloſe Mowing is every Way an Advantage.

CHAP. X.

Of Mowing.

THE Ground being thus carefully laid for Hay, the Farmer has no farther Care but the knowing when to cut it. This he muſt carefully obſerve, for there is a proper Time of Ripeneſs; and all after, as well as all before that, is ſo much Loſs.

When a Piece of Ground is laid early, and has been properly aſſiſted by Manures, it will often be ready to cut in the End of May.

There are thoſe, who, in a forward Seaſon, cut it earlier, taking the firſt Appearance of Ripeneſs, imagining they are ſecuring their Intereſt, by preparing early for a ſecond Crop; but they often loſe more in the firſt, than it is poſſible they ſhould get in the latter. The firſt Crop of Hay is the great Article, and ſhould be regarded accordingly: the other is always trifling in Compariſon.

There is a Time of the Year when every Plant flowers; and Graſs, like others, has its Seaſon. If we examine in other Plants the Courſe of Nature, we ſhall ſee that though their Leaves ſtand pretty well during the flowering, they wither when they come to ripen the Seed. The Leaves of Graſs go to the Quantity of Hay as well as the Stalks; and are indeed the beſt Part; they are not therefore to be neglected for the Sake of the other. The ſeveral common Kinds of Graſs, in well managed Paſtures, get into Flower in the End of May, or Beginning of June, this therefore is the natural and proper Seaſon for cutting of them. The Hay will not have its due Quantity till the Stalks are full grown; but after that Time, the Leaves will fall ſo faſt into a State of Decay, that there will be more loſt by twenty Times at the Bottom, than there is gained at the Top. The Price of Hay is

very conſiderable, but that depends upon its Goodneſs; and this upon two Articles, the Time of cutting, and the Manner of making; and upon the former little leſs than on the latter.

The Faults in making are moſt obvious, but there may be poor Hay got from a very good Piece of Ground, either before, or after the right Seaſon of Mowing; while that which is truly excellent can be had only by ſeizing the right Time.

The fine green Colour of Hay is very much valued. This is owing, in a great Meaſure, to the making; but then it muſt be in the Graſs itſelf, otherwiſe all the Care that can be taken in drying it, is all in vain: a proper Method of Turning will preſerve a Colour, but it cannot give it: that muſt be from Nature.

This fine Colour depends, like the reſt of the good Qualities, on the Time of Mowing, or the Degree of Ripeneſs of the Graſs. When it is juſt in Flower, the Leaves are freſh and green; but when it is got to Seed, they grow brown: this is the firſt Step toward their Decay, and this is the Change of Colour which no Art can recover.

While the Graſs is but coming to Perfection, it is too green; when it has ſtood too long, it becomes brown; and that fine pale green Colour ſo eſteemed in Hay, can never be obtained by any Art afterwards.

The Smell of Hay is another Article of its Value, and this, like the reſt, muſt be preſerved by Care in the making, but it muſt be entirely owing to the Time of cutting.

Hay that has ſtood too long, has the Appearance of ſo much Stubble, and has no more Smell; whereas at the Time of the Graſs flowering, which is its juſt State of Perfection, there is one of the pleaſanteſt Flavours we know, from the cutting through of the Stalk, and the evaporating of its Juice in drying. The Colour of the Stalk fades as well as that of the Leaves, after the due Seaſon is over; and we ſhall ſee this plain enough, if toward Autumn we look upon ſuch Graſs as has run up among Buſhes, out of the Reach of the Scythe and Cattle. The Stalks of this were at one Time in a Condition to make the fineſt Hay, but after that we ſee them dry, brown ſticks, and without Taſte, Smell, or any other Quality.

The whole depends upon this Principle before eſtabliſhed, there is a State of Perfection in all Vegetables, and the Art of the Huſbandman muſt be employed to obſerve, and his Prudence to ſeize it. This State of Perfection with reſpect to an entire Plant, is juſt the Time of its flowering. When we mean to ſave the Seeds of any Thing, we muſt ſtay longer; and, in that Caſe, we ſee the Plant wither; but the Time of its Perfection is juſt the coming into Flower. The Apothecary buys his Herbs for Diſtilling at that Period, knowing that juſt when the Flowers are opening, the Stalks, Leaves, and every Part are the fulleſt of Virtue: and it is ſo in Graſs. The Farmer muſt make the ſame careful Obſervation, and the ſame Choice.

Now that we have given the Reaſons for chuſing Graſs at ſuch a Period for Mowing, it is proper to deliver the Marks by which it is known to be ſo. Let the Farmer to this End take in the Examination of the whole Plant. It may be ſeen by the Heads alone, but as the Effect of their ripening ſhews itſelf at the Bottom alſo, let him take in both.

Thus let him go into his Graſs Fields from time to time toward the End of May, and during the Beginning of June, if not prevented ſooner by the full Ripeneſs. Let him examine the Stalks which will be now grown up in Height, and ſee how their Tops approach toward Ripeneſs; he will perceive from time to time the little Heads ſwell, and at length there will appear a few white Threads. Theſe, in ſome Kinds of Graſs, only ſhew themſelves on the Surface of the Buttons; and, in others, hang from them a fifth Part of an Inch. This is the Flower of the Graſs, and when it appears, the Hay Time is near.

He muſt not judge from one or two Plants in a Hundred, but ſee when the whole Field thus gets into Bloom; and then he muſt be critical in his Examination. The fuller and freſher it is at the Top, while the Bottom remains perfectly ſound and good, the better; therefore that is to be examined for the final marking of the Time. Let the Farmer open the Graſs with his Hands in ſeveral Places, down to the Ground, and obſerve carefully how the lower Part looks: as theſe flowery Parts, or the Top ripen, the Bottom will grow brown. This is the firſt Mark of its Decay. After this the Top will get nothing; and the Bottom will loſe a great deal, ſo this is the Time for the Mowing.

The Mowers are to be ſent in, and the Ground having been thus prepared and levelled for them, they have no Excuſe if they do not cut it cloſe. Theſe are a Sort of People, as every one knows who has had any Concerns with them, who are very apt to ſlight over their Work, and ready to ſeize upon any Pretence for doing ſo: they have no Conſideration that their Careleſſneſs is the Loſs to the Farmer, perhaps of a tenth Part of his Crop: but let him take Care of it himſelf: as he has according to theſe Directions prepared the Ground for them, let him follow them, and frequently put them in mind of it: they will thus be brought to do much better than they ever will when left to themſelves; and the Addition to the Quantity of the Hay will very well pay the Farmer for his Care and Attendance.

We commonly ſee the Farmers about London, riding in their Grounds among their Haymakers, but this is an idle Cuſtom: let them walk after their Mowers, and they will do themſelves twenty Times the Service.

The Buſineſs of Hay-making is generally done much better than that of Mowing; and if any Omiſſion be made in it, 'tis eaſily ſeen, and there is Time to rectify it; but in the Mowing, the Miſchief is ſcarce to be ſeen, unleſs the Scythe be followed; and when it is once done, there is no mending it. The Graſs being down, is to be carefully dried; and in this there is ſo much Difference between the Practice of the Farmers in the Parts of the Kingdom where

Husbandry is most improved, and the others, that it should be set in the strongest Light, to render those Improvements universal.

CHAP. XI.

Of Hay-making.

THE Grass being down, is to be turned and dried, and then it is Hay. This is the whole Process in a few Words, but there must go more to the well understanding of it.

We have directed the Farmer to cut down his Grass at a Time when it has a full Body, and a fine Colour; and we shall now shew the Methods by which it may be preserved, and the Neglects by which in many Places it is lost.

In the less improved Parts of the Kingdom, the Hay-making Season comes very late. They allow little Manure to the Grounds, they lay them up late; and, consequently, in the most favourable Summers they have but a poor Crop of Hay, compared with those who take better Measures; and in hot and dry Seasons, they have scarce any.

In these Places the Farmer never thinks of cutting his Grass till it begins to look brown at the Top, which indeed it does sooner than it would if better supplied with Nourishment; and then it is failing at the Bottom.

At this Time he sends in the Mowers, who cannot cut close because of the Unevenness of the Ground; nor does he insist upon it, for he imagines that the more they leave, the better will be his Aftermath. The Error of all this we have shewn, that it may be practised no longer; but we are very sensible that it is too common in a great Part of the Kingdom at present. When the Grass is thus cut, it has neither a good Colour, nor good Smell; so that no Art or Management could make fine Hay out of it; but if that could, it has not the Chance, for the Hay-making is as little understood as the Mowing.

They let it lie in the Swarth, and think they do enough if they turn it two or three Times in the Sun, never putting it into Cocks, till they suppose it nearly made; they then put it up in large Cocks, and let it stand a Week or ten Days to sweat, and then take it home, and put it up in a great Rick, the Labourers rideing in Triumph in the Cart, as if they had done their Business notably.

Many have wondered at the Difference between the Hay about London, and that in remote Parts of the Kingdom: it is indeed extreamly great; but none will be surprized at it who sees this Reason. The whole Management is bad there; and, in general, good in every Part here. We shall lay down the best Method in a few Words, and hope the improved Farmer will find his own Practice agree with it, and that others will mend by following of it.

The great Care in this Point, is to preserve the Colour. The Grass being cut in the Condition we have named, will be of a fine green, and this is to be preserved; for the Farmer may be assured, that a Loss of Colour is always attended with a Loss of Taste, and Loss of Smell; and with a certain Loss in the Article of Price.

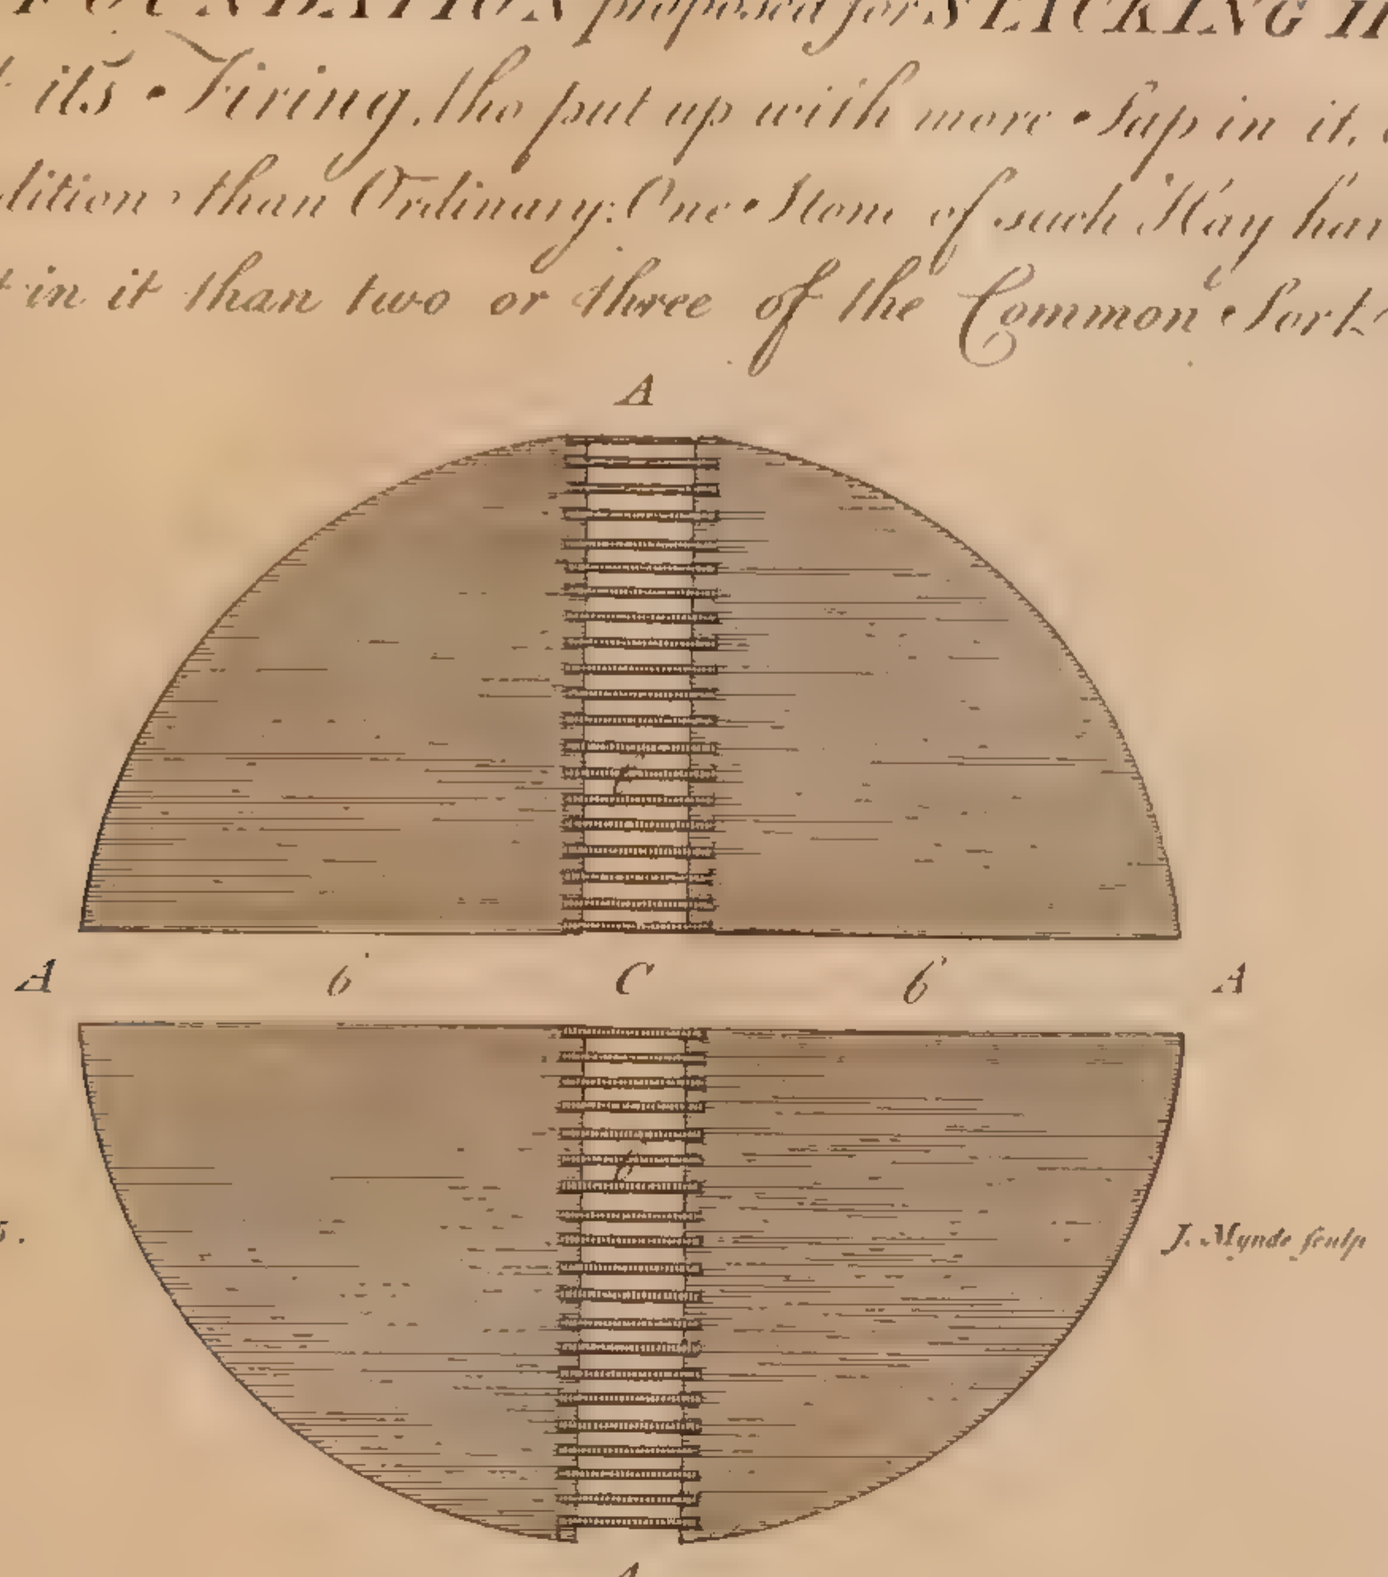
To preserve the Colour of the Grass, and give it the full Sweetness when it is mowed, it should be let to lie in the Swarth two Days and a half. At the End of this Time it is to be spread out, this is properly what is called tedding of the Hay; and thus it is to lie exposed to the Sun during the Remainder of the Day. Then it is to be made up into little Cocks, which are called Grass Cocks, at Evening, and so left for the Night. The next Morning, as soon as the Dew is off the Ground, these Grass Cocks are to be spread, and thus the Side of the Grass that had lain undermost, will get dried. In this Condition it lies all that Day. Toward Evening, it is to be cocked up again into the same Sort of little Grass Cocks as before.

This is a reasonable, and excellent Practice, for it at the same Time gives the Hay all the Advantage of the Air and Sun during the Day, and defends it from the Dews of the Night, which can do little Harm when it is gathered up in these Heaps; though while it lay spread upon the Ground, they would have greatly interfered with the Drying. I have seen when this Caution of cocking up at Evening has been omitted, that the whole Quantity which was very forward in drying the Day before, has been rendered damp and soft, and brought into a worse Condition than at first; for the Water of the Dew is more hurtful to its Colour than the natural Juices of the Grass. In this Condition the Smell and Colour have been greatly impaired, and there has been afterwards no Way of recovering them. This is not so bad as the Practice of the remote Farmers, whose Hay is always brown, and Mow-burnt; but it is very much inferior to the true and careful Method, and never fails to reduce the Price.

In the proper Method of Hay-making after the Tedding, and Grass Cocking, so far as we have named, the Hay is to be spread again, and drawn up into a Kind of Lengths, which they call Windrows. This is a very good Condition for drying, and what is a great Advantage also, these Windrows are easily thrown up into Cocks, for they lie conveniently for that Purpose: thus when the Weather is fine, the Hay has the full Advantage of it, as it lies spread out in these Rows; and if Rain come on, the Hay-makers can toss it into Cocks in a few Minutes, in which Condition it will get very little Damage, and is ready to be spread again to take the Advantage of the next fair Blast.

From these Windrows the Hay is to be thrown into large Cocks, and in these to stand through the Night, and for some Time afterwards; but then it is not, though pretty well made, to be carried home directly from the Field in this Condition. The Outside of one of these large Cocks will be very dry, while there is Moisture in the Middle, and the Farmer's Business is to have his Hay all alike; not only some of the Juices of the Grass will remain in that which has been in the innermost Part of the Cock, but it will sweat a little with lying together: therefore these Cocks must be

PLAN of a FOUNDATION prepared for STACKING HAY upon, to prevent its Firing. Tho put up with more Sap in it, or in a greener Condition than Ordinary: One Stem of such Hay having more Nourishment in it than two or three of the Common Sort.



J. Mynde sculp

A Scale of Feet.

A,A,A,A. The Circumference of the Foundation, laid with dry Stones or Brick, & raised only one foot above the Surface of the Ground.

B. B. B. B. Four Cross Gutters, each one foot Square in the Bore, meeting in the middle of the Foundation to be all covered over with loose pieces of Wood or Stone as one of them is in the Plan for Example.

C. In the Center of Communication to all the four Gutters, place a Common Stack Upright with a round Bottom, stuffed with Straw, & as the Cock raises, draw up the Stack a foot or two, till it be quite finished a top; then draw out the Stack, & leave its Track open a top as a Vent to the perpendicular Flue, till the danger of overheating be over, when it may be covered over & Thatched.

This greenish Hay begining to heat, soon rarifies & expands the Air contained in the perpendicular Flue, which is continually expelled a top, and succeeded by the Indraft of the cool dense Air from the Gutters below so long as the least heat remains in the Cock, which will prevent firing overheating & Mow-burning over much, especially if it be considered that no part of this Cock is distant above three foot from the ambient Air without or the Circulation thereof in the Center Flue.

When the Cock is cured Thatched & quite cooled, the Gutters should all be stoped on the Outsides with Wisps of Straw, or the Hay will not keep so long & well as it might do, But if intended to be used in 3 or 4 Months after Stacking, keep the Gutters open the whole time, but the Flue a top must always be closed in wet Thatching time.

thrown to Pieces, and the whole Quantity of the Hay once more ſpread upon the Ground. If good Weather follow, it will thus dry in a very compleat and perfect Manner: three Hours Wind and Sun going farther under theſe Circumſtances than a Day at another Time.

If the Weather continue favourable, the Buſineſs of Hay-making is thus happily finiſhed; but if Rain come, we muſt give the Farmer his Leſſon, which is, not to turn the Hay that has catched the Wet as it lay ſpread, but to let it dry as it lies, which, theſe Showers being ſeldom laſting, it will quickly do. On the contrary, if the over Care of the Hay-makers ſhould turn the Graſs thus nearly dried, and then wetted by Accident to the Ground, the Damp of the Earth would greatly injure it. On the other Hand, as the Wet is ſlight, and the Sun and Air have great Power; the Top will preſently dry again lying as it is.

After this ſpreading from the Cocks, the Hay may be thrown together for Convenience of Loading, and is in perfect good Condition to carry in.

This is the whole Method of Hay-making, when every Thing has been properly managed; but, in other Caſes, farther Care may be neceſſary; and we ſhall be defective, if we do not inform the Farmer in all poſſible Particulars.

We have directed him in preparing his Ground at the Approach of Winter, or, in the worſt Caſe, early in the Spring to get up all large Weeds: and we have directed him in the Article of Hay-making, for a clean Piece of Graſs Ground thus prepared. On the other Hand, when this due and timely Care has been neglected, more Time, and greater Caution will be required in the making of the Hay. When there are thick Weeds among the Graſs, there muſt be more Time to dry the Whole than where the Graſs is clean, for theſe have more Moiſture, and are, conſequently, longer in parting with it. And if the Hay be put up damp with them among it, there is no End of the Miſchief, for they will give afterwards, and ſpoil every Thing near them.

In whatever Condition the Graſs be, the more Hands are employed in making the Hay, the better; and a very careful Eye muſt be kept over them, to ſee they do their Duty.

CHAP. XII.

Of the Aftermath, and the Winter Uſe of Graſs Grounds.

WE have conducted the Farmer from the clearing and preparing his Ground, to the making and carrying Home of his Hay; and we are now to ſuppoſe the Ground cleared, and to conſider the Uſe it may be put to, during the remaining Part of the Year.

The Hay of the firſt or great Crop being carefully ricked, that Trouble will be entirely off his Hands. If the Weather be favourable, his Intereſt is to keep it till perfectly dry upon the Ground; but if it be precarious, he may ſtack it ſooner, obſerving the Caution we have given in one of our firſt Numbers of this Work, to keep a Hollow in the Centre of the Stack to prevent its heating.

In either Caſe the Hay being out of Hand, his Care is to return to the Ground from whence it was cut, and make the beſt Advantage of this he can.

In the more improved Counties where the firſt Crop comes early, they expect a ſecond; and keep the Ground as carefully for this as for the firſt.

We have ſhewn it is an Error to ſuppoſe the old Stumps grow up into a new Crop, therefore that the cloſer the firſt is cut the better. This will, to the common Reader, ſeem againſt Reaſon, but we can aſſure him it is the Doctrine of Experience. If he will obſerve two Graſs Grounds, the one of which has been cut cloſe; and the other in a more careleſs Manner, with long uneven Stumps left on it, he will find the cloſe cut Piece will yield the new Shoot quickeſt, and will keep above the other in Height throughout the Growth.

This is to make the ſecond Crop of Hay: but, at the beſt, that is much inferior to the former; and, upon the Whole, the Huſbandman is often in the Wrong to depend upon it.

None but good Ground, and what is kept very well in Heart, will afford a ſecond Crop at all worth cutting; and even this not well, unleſs the Weather favours. At the beſt therefore, the Profit is but moderate, and the Hazard very conſiderable; ſo that in many Caſes, it is better to uſe the Ground for feeding.

The Farmer who lives in a County where Manure is ſcarce, and where there is not all this nice and exact Care uſed about Graſs Grounds, muſt not expect all the Advantages we name, to him who uſes more Art, and more Expence in his Improvements. Thus, as it is not every Ground in the moſt improved Counties that will yield a ſecond Crop of Hay to Advantage, ſo in the leſs improved Grounds, the Huſbandman is not to expect one Crop every Year.

The Crop of Hay from the Graſs Grounds, is like that of Corn on the plowed Land, it is the utmoſt the Soil is able to produce, and it exhauſts it accordingly. Therefore as in the Counties where leſs Improvement by Manure is uſed, a Fallow once in three Years is allowed to recover the Heart of the Ground; in the ſame Manner in ſuch Places, the Crop of Hay ſhould be once in three Years ſpared to give Strength for the others.

There is ſome Advantage however in this, which may be called the Year of Fallow for the Graſs, in that it is not altogether uſeleſs; for, though the Graſs is not to be mown that Year for Hay, it may be eaten by the Cattle. There will be the more upon it for them, becauſe the Heart is not ſuffered to run up to Head for Hay: and all the while their Dung as they feed upon the Ground, will be enriching and improving it.

This Matter of the Graſs gathering Strength in the Year wherein there is no Mowing, will be perfectly underſtood by what we have before ſaid of the Growth of Plants in general; which is in all of them thus. The Root ſupplies the

Leaves

Leaves with abundant Nouriſhment, while there is no Stalk. When that Stalk grows it demands a great deal, the Leaves therefore have leſs; and when the Seed comes toward ripening, all the Care of Nature is directed thither, that being the Intent in the Growth of the Plant.

Now this ſhews very plainly the Advantage of the Year of Fallow, as it may be called, to Graſs Grounds, that is, the Year in which they are fed, not mowed. The Growth of the Graſs into Stalk exhauſts the Root, and ſtarves the Leaves. This is what is ſuffered in the Hay Seaſon, and it is therefore the Hay Crop exhauſts the Land ſo much more than the feeding.

When a Piece of Graſs Ground is kept a whole Year for feeding alone, the Stalks are eaten off as they would riſe, and the Leaves being alſo conſtantly cropped, new ones are continually ſent up in their Places; which being again eaten down before they are of a Size to exhauſt the Roots too much, the whole Plant is kept in a Condition of conſtant Vigour, and the Roots in Strength and Heart. The Ground alſo is leſs exhauſted by the Growth, and all the Time refreſhed by the Dung, ſo that there is every Way Improvement.

In this Manner the Year of Fallow is to be conducted in thoſe Counties, where the Want of Improvement renders it neceſſary: with us the Aftermath is to riſe to a new Crop for mowing, or to be eaten on the Ground, according to the Circumſtances and Occaſions of the Farmer.

In the eating it off, the larger Cattle are to be let on firſt, and Sheep afterwards. They will eat where the Oxen and Cows can find nothing more; and when the Ground is fed down in this Manner, it is to lie a few Weeks to recover, and then the Cattle are to be turned in again. This, with the Manuring and Dreſſing as we have directed, compriſes the whole Management of Paſturage.

BOOK VII. PART II.

Of the Cultivation of artificial Graſſes.

CHAP. XIII.

Of artificial Graſſes in general.

WE have obſerved already, that theſe are principally of foreign Origin, and all of them are to be ſown and raiſed by Culture, none growing naturally wild in whole Fields, as the common Graſs does, which is therefore called natural, in Diſtinction from theſe raiſed by Art and Culture.

As theſe ſeveral Kinds are moſtly of foreign Extraction, the Method of Culture is alſo copied from Abroad, but we have greatly improved it. 'Tis the Character of the English to receive and adopt the Productions of other Countries, and to make them our own by our Improvements. We have in no Article done it more than in this of the foreign Graſſes; the Seeds of which we have from Abroad, and raiſe artificially here, whence their common Name.

There are often Reaſons why it may be proper to take a Piece of Ground out of Corn, and ſow it with ſome of the Graſſes. This uſed to be done in the old Huſbandry, with the common Graſs Seed, but at preſent the Cuſtom is by ſome of theſe Kinds, and the Profit four, five, or more Times greater.

There are the greateſt Reaſons for varying a Crop from time to time. And theſe anſwer excellently for that Purpoſe, giving the Land an advantageous Kind of Fallow, while they at the ſame Time afford a very profitable Produce.

The Huſbandman ſees often the Advantage of ſowing Corn or Pulſe, where Graſs would hardly grow, but this is raiſed at an Expence of Manure and Tillage, and laſts no longer than one Seaſon: theſe Graſſes will in the ſame Manner grow, with proper Management, on ſuch Ground as will not bear common Graſs; and they will alſo follow Corn when it has quite exhauſted the Land, very ſucceſsfully.

The Reaſon of this we have given before, which is, that Corn rooting very ſlightly, can exhauſt only the ſuperficial Part of the Soil, ſo that theſe which go deeper find Nouriſhment: and at the ſame Time fallow and improve the upper Part, which will be wanted for Corn again.

We have ſhewn that the Pulſe Kind all are Improvers of Land by this Means; by ſhading the Surface and mellowing it, while they draw but little Nouriſhment from it; but theſe Graſſes do much better, they cover the Surface more cloſely, ſo that there is more Advantage to the Ground, and they penetrate deep for their Nouriſhment. They differ from Pulſe in this, that they require a great deal of Food, but then they take it from ſuch Part of the Ground as is not called upon for Culture.

Every thing that enriches Land acts upon one of theſe two Principles, as Manure or as Fallow. The Manures give a Fertility from themſelves. The Fallow leaves the Ground open to receive it from the Air: but it will even get it any where ſo it have Reſt.

We ſee in Gardening that when much Manure is not uſed, the Ground is to be trenched once in two or three Years, to make it fruitful. This trenching is changing that Part on which Plants ſtood, and from which they received Nouriſhment. They dig to a Depth ſufficient to raiſe a new Parcel of Mould; and they bury the former Surface in the Hollow from whence they throw

up that. In the ſame Manner theſe Graſſes act, though under a different Form, and indeed every Way more ſucceſsfully. In that Caſe the ſuperficial Earth wherein the former Crop grew, is thrown under the new Surface, where it gathers freſh Strength, and will be fit to nouriſh Crops again. In this Caſe of the Graſſes, that under Part of the Soil, inſtead of being thrown up, is exhauſted by Plants, whoſe Roots go down to it; and the upper Part lies at reſt, or at leaſt with very little Demand of Nouriſhment from it, and is all the Time ſheltered by the ſpreading Branches of the Crop, and enriched by the Dews and Rains; and occaſionally by the Dung of Cattle fed on the Growth as it ſtands.

This is the Syſtem of Improvement by artificial Graſſes, and in this Account it is plain, that the Practice of the Field exceeds that of the Garden, as the Succeſs indeed evidently confirms.

CHAP. XIV.

Of Clover, its moſt proper Soils, and the Manner of ſowing.

WHEN we ſpoke of the artificial Graſſes, as being the natural Product of other Countries, we made a Reſerve in Favour of Clover, by ſaying only, they were ſo in general. As to this in particular, it agrees in the Manner of raiſing and cultivating with the reſt; and we have the Seed of ſome Kinds from Abroad; but it is in its Origin a Native of our own Country. The common red Trefoil, vulgarly called red Honey Suckle, is Clover in a wild State; and there is no other Difference between that and what we raiſe by Culture, but what the richer Soil and Addition of Dreſſings has originally made.

Clover, and the other Plants raiſed under the Name of artificial Graſſes, have not the leaſt Reſemblance of Graſs in their Form, or Manner of growing, the Uſe they ſerve in ſupplying the Place of Graſs, is what has occaſioned their being called by the ſame Name.

Clover is a low Plant, and naturally grows leaning on the Ground. The Roots are fibrous and whitiſh, ſome few ſmall ones ſpread under the Surface, but the greater Part penetrate ſtrait down. To draw up a Root out of common Ground, one would ſuppoſe it did not go down above two or three Inches; in a well manured and well tilled Field, where the Earth is light and mellow, the longeſt Fibres carefully drawn, will meaſure about ſix Inches; but they may be traced with Care to fifteen or eighteen Inches; and do really penetrate much farther, but that they are then very fine, and ſcarce to be diſtinguiſhed.

The Stalks, when Clover is well ſupplied with Nouriſhment, are numerous, jointed, and ſpreading. The Leaves grow from each Joint of each Stalk, and many from the Root. Each Foot Stalk has three upon it, and they are often ſpotted in the Middle. The Flowers are red, and ſtand in little Tufts or Cluſters, at the Tops of the Branches. They are of the Shape of the Pea Bloſſom, but very ſmall, narrower, longer, and not ſo open; and the Seeds are contained in a Kind of little Pods. There is a Drop of a Honey-like Juice at the Bottom of each Flower, whence it obtained the Name of Honey-ſuckle, a Name given alſo by many to the Wood-bind.

This is the general Deſcription of Clover, which differs according to the Degree of Culture in Bigneſs, and the Form of ſpreading or ſtanding more erect, but not otherwiſe. The wild Honey-ſuckle, which is common wild among the Graſs of dry Paſtures, is an Advantage to it. This is low and ſmall, and in a great Meaſure lies down upon the Ground: in Fields where it is ſown, and carefully cultivated, and is raiſed from Seed that was got from cultivated Plants, it is larger and more erect. The Leaves alſo are larger, and ſo are the Heads of Flowers, and the ſeparate Flowers in them. We have alſo what we call the Iron Clover, which is very ſweet and leſs than this, but it differs no otherwiſe than from the ſame Kind of Accidents. The DUTCH and FLEMISH were the People who taught us the Uſe of Clover, and they raiſe it to a great Advantage at this Time, the Quantities they ſometimes obtain from an Acre being too great for the Credit of thoſe who have not ſeen their great Care and excellent Managment.

With Reſpect to the Soils for Clover, the richeſt always ſucceed the beſt with it, and there is none ſo good but it may be worth while to raiſe Clover upon it. There is Land too rich for Corn, for it will make it too rank, but this will excellently nouriſh Clover; and on the other hand, it is a bad and ignorant Practice to ſow this Species on poor Ground, for it will never come to any thing.

Whatever would be needful to do to ſuch Land to ſuit it to the bearing of Corn, the ſame will be neceſſary to make it bring Clover to good.

In all this we mean only to ſhew what is neceſſary for Clover, but we ſhall inform the Farmer, that in the common Courſe of Things it is not to be ſown on rich Land new broke up; or on ſuch as has been dreſſed and prepared purpoſely; but is to follow Corn as we have mentioned before, and will then ſerve in the double Capacity of yielding a rich Crop itſelf, and preparing the Land for Corn again.

As to the different Kinds of Soils, the beſt for Clover is a light, warm, and rich Earth. Such as is principally what we call mellow Earth, but with a Portion of ſomewhat loamy, for otherwiſe the pure mellow Earth alone is apt to lie too heavy for Clover.

A very rich Loam is an excellent natural Soil for it.

Whatever Land be deſigned for Clover muſt be brought into perfect good Tillage, and for this Reaſon it very well follows Corn, as in that Caſe it comes upon a Land which has been well wrought, and with Reſpect to the Nouriſhment it requires, is not exhauſted. This we have explained already.

If the Farmer ſhould chuſe to break up a Piece of Ground on Purpoſe for Clover, the Freſhneſs of it will make that Growth ſucceed, though in its Nature it ſhould be improper. As to other

Soils different from thoſe we have named, if the Farmer finds it convenient to his Affairs to uſe Clover upon them, he muſt manure them accordingly. Marle, Dung, Lime, or the other Manures in general, which are uſed to prepare Land for Corn are alſo the proper, and they are the only Methods of preparing it in this Caſe for Clover.

The common Cuſtom of ſowing it with Corn is liable to ſome Objections, but they may be got over by a proper Management, and then this will be found a profitable Method.

Nothing is more common than the ſowing Clover with Barley, in which Caſe it is apt ſometimes to over-power the Barley in its firſt Growth, and will then do it great Damage. In a wet Summer the Clover will grow at a great Rate, and the Damage of the Barley will be very great this Way; and on the other hand, in a very dry Summer it is too apt to fail.

To prevent the Damage of the Barley by the Growth of the Clover, the beſt Way is, though they are ſown on the ſame Ground, not to ſow them at the ſame exact Period. When the Farmer intends to have a Crop of Clover and Barley upon the Ground at the ſame Time, let him ſow the Barley alone in the uſual Manner, and wait till it is three Inches high above the Ground: then let him ſow his Clover by Means of a Hand Drill. This will anſwer the Purpoſe extreamly well. The Clover will do better than when the Seed is ſcattered at Random; and not the leaſt Damage will be done the Barley, by drawing the Drill by Hand through the Field, the Perſon entruſted with the Work being tolerably careful.

In this Way the Barley will have got ſo much Head before the Clover ſhoots, that it will be too ſtrong to be over-powered and ſtarved by it; and at the ſame Time, if the Seaſon prove dry, it will be high enough to defend the Clover, which otherwiſe, in a wet Summer, would have over-powered it.

We have ſaid that Clover may be ſown alone, but when it is judged more proper, as is commonly the Caſe, to ſow it with another Crop, Barley is not the only Kind: it may very well be ſown with Oats.

When a Crop of Corn is to have Clover among it, leſs Seed ſhould be uſed than if it were to grow alone, and as to the Manner of ſowing it, if that be done by Hand with the Corn, there ſhould be choſen a fine mild Day for the Purpoſe; becauſe the Seed is ſo light that otherwiſe it would be blown about, and left on the Ground in a moſt irregular Manner. But the beſt Way by far is, the drilling it in afterwards.

The Time of ſowing it muſt depend upon that of the Corn with which it is to be ſown; and in this Caſe the little Time after is very well worth while waiting, for though it keep the Clover back, it brings the Corn forward: on the other hand, if the Farmer be deſirous of having a Crop of Clover early in the Ground, though ſown with Corn, the beſt Method is to ſow it with black Oats, and get them in as early as poſſible.

The Spring Corns are not the only Kinds among which Clover may be ſown. It will thrive very well with Wheat and Winter Rye, if ſown with them in the Beginning of October. Indeed there are Advantages attending this Method, that are to be had with no other. We have obſerved that a dry Summer hurts a Crop of young Clover extreamly. There is no Plant that more requires Rain in the Time of its firſt ſhooting, for ſome Months. It is for this Reaſon that when ſown very early with black Oats it always thrives, becauſe it has then the Advantage of the Rains of Spring. But when it is ſown in the Beginning of Winter, with Wheat or Rye, it fares ſtill better, for then it is ſure to have a long Time of wet, before there be any Sun or Drought to hurt it. In this Caſe alſo it ſtrengthens itſelf in the Ground extreamly, and is always found very thick and flouriſhing on the reaping of the Corn.

Some might be apt to fancy that a thick Crop of Clover growing among Wheat, in this Manner, would impoveriſh that Grain, or be impoveriſhed itſelf, becauſe of the great Quantity of Nouriſhment it requires; but we have ſhewn already why they do not interfere with one another, the Wheat rooting ſuperficially, and the Clover deep.

When Clover is ſown alone October is the moſt preferable Time, though the Spring be commonly choſen. Very ſevere Weather may hurt it, as it will almoſt any thing, but Clover being a Native of our Country, is not a very tender Plant: if the Winter be tolerably mild it will make very vigorous Shoots, and ſtrengthen itſelf in ſuch a Manner in the Ground, as to yield a very early and very plentiful Crop in the ſucceeding Summer; after which it will continue firm in the Ground, and encreaſing in Value. There is alſo this particular Advantage in ſowing Clover in October, that it comes up in a Manner free from Weeds, whereas in Spring they riſe in Abundance among it, and many of them being of quicker Growth, they will over-power it.

Many, when they are about to lay down a Piece of Corn Land for Graſs, chuſe to ſow it with Ray Graſs and Clover; but in this Caſe the beſt Method is to ſow them at different Times, though they are to grow together afterwards: thus the beſt Corn for ſowing with Ray Graſs and Clover is Wheat, and the beſt Way of doing it is this. The Wheat being ſown at its natural and uſual Time, let the Seed of the Ray Graſs be ſown with it; this will be naturally ſometime in October; and let the Clover be ſown in the following Spring. This muſt be done early, that the Clover may, during its firſt Growth, have the Advantage of the Rains of the Spring, and be got to an Height in Summer.

There is alſo, in the common Way of Huſbandry, another Reaſon for ſowing it very early in the Spring in this Caſe, which is, that nothing more can be done as to the Covering it at that Seaſon, but rolling the Field; now rolling, while the Corn is very young, will help it; but if it ſhould be done when it has got into Stalk, it will hurt it extreamly by breaking the Stems, which very difficultly recover ſuch an Injury, after they have arrived at any Strength. This we have explained at large in a preceding Part,

under the Article of Rolling, and therefore need enter no farther into the Matter here.

But we ſhall add for the Information of the Farmer on this Head, that when he thus ſows two Graſſes with his Wheat, he is to let in the laſt in the ſame Manner as with the Barley, if he will follow the moſt reaſonable Practice. Thus let him in this Caſe ſow his Ray Graſs with the Wheat in OCTOBER; but when he comes in Spring to ſow his Clover, let it not be done in the common random Way by Hand, but let him uſe the Hand Drill, and ſow the Clover juſt as we have directed when it is to grow with Barley.

As to the Damage that the ſevereſt Winter can do to Clover, it is not nearly ſo great as that of a dry Summer to ſuch as has been ſown late in Spring. If the Roots be tolerably covered, and the Soil lie any Thing cloſe about them, they will get no Harm; and for that Reaſon when the Farmer finds Danger of the Winter, with reſpect to a young Crop of Clover that is alone, his beſt Method is to turn in his Sheep to eat it before the Approach of the ſevere Seaſon. The Leaves and Stalks which would have been perhaps in a great Meaſure deſtroyed by the Froſts, and long lying of Snow, will have anſwered their Purpoſe, and been eaten; and the Root being better ſecured than before, by the trampling of the Cattle, which fixes the Ground about it, will ſtand perfectly well; and having no Head to ſupport during the Winter, it will ſend up its Leaves and Stalks vigorouſly in the Spring.

The Huſbandman thus underſtanding the Nature of Clover, the various Manners of ſowing it, and the Reaſons for each: is to conſider next the Nature and Quality of the Seed; and to take Care that he chuſes ſuch as is new, and of a good Kind. Among the ſeveral Quantities of Clover Seed offered to ſale, the Huſbandman will find a great deal of Variety of Colour; ſome is yellowiſh, ſome rediſh, and ſome blackiſh. Theſe are three Colours that are to be his firſt Guide in the Choice; the yelowiſh is the beſt, and to have the true Tint, this ſhould be a greeniſh yellow; the rediſh is the next good Colour, that which is black is worſt: but the Colour is not all that goes to the Choice, it muſt be ſound and freſh.

It ſhould be clean, large, and gloſſy on the Surface, which is always a Proof of its Goodneſs, as a duſty heavy Aſpect ſhews it has been damp, or has had Inſects in it. The Seed being underſtood as to its Marks of Goodneſs, the next Conſideration is the Quantity; about this there is much Diſpute among thoſe who have moſt Right to know, that is, the practical Farmers. Some ſay ſix Pound is enough for an Acre, others uſe twelve or fourteen Pound.

In general, we ſee the Practice is wrong in allowing too much Seed; but thoſe who uſe this ſmalleſt Quantity err on the other Side, for ſix Pounds is too little. Clover is a Plant that never grows to any conſiderable Size; when it is beſt planted it is but ſmall in Compariſon of other of the artificial Graſſes, therefore the Plants are not to be kept at that Diſtance which the others be with Advantage. Eight Pounds of good Seed is as little as ſhould be allowed to an Acre in any Condition; and thoſe who go beyond ten, allow as much ſuperfluous, as thoſe who ſow but ſix too little; nine Pound may be called a good Quantity: and notwithſtanding all I have heard, to ſpeak from what I have ſeen, are repeated Trials, the largeſt Quantities yield not only the ſmalleſt, but the worſt Crop.

This is a Conſideration of the more Conſequence to the Farmer, in that too many of thoſe who have written to inſtruct him, run into the common Error, and ſay, that a very large Quantity of Seed, larger than the moſt I have named, will yield him ſo much the larger Crop. This has been the general Error: the ſowing too ſparingly is an Error alſo; and though it cannot be attended with ill Conſequence in thoſe Plants which will grow to a very large Size; or ſend out numerous Stalks, with Ears on them, as in Corn, yet in Reſpect of Clover, and all the like Kind, it may defraud the Farmer doubly; firſt in preventing him from ſo good a Crop as the Land would very well have borne, and next in not doing the expected Service in preparing the Ground for Corn afterwards; for this cannot be perfectly done, unleſs it be entirely covered.

CHAP. XV.

Of the feeding Cattle on freſh Clover.

THERE are two diſtinct Uſes for which Clover is ſown; the one is, the feeding Cattle upon it as it grows; and the other, the laying it up for Mowing, for the making it into Hay: in this it perfectly reſembles the natural Graſs, and anſwers both theſe Purpoſes in the ſame beneficial Manner. But there muſt be Care in the feeding it on the Ground, otherwiſe it may be attended with Danger.

We know that the richeſt Foods on our own Tables are capable of doing us the moſt Harm. They will often breed Diſtempers in us, and Cattle are no more exempt from them than we are.

Clover is a very rich Food for them, and they are ſo fond of it, as to eat of it often immoderately; wherefore unleſs Care be taken, eſpecially when the Clover is rich, and they are ſuddenly turned into it, they will get Diſorders. The Quantity and Richneſs of the Nouriſhment that is in Clover are ſuch, that an Acre of it will, on a moderate Computation, feed as many Cattle as ſix Acres of the common Run of Paſture Grounds: but, in order to make the moſt of it, they ſhould not be turned into the Field to trample it down at random; but it ſhould be mowed freſh and freſh as it is wanted, and given them green in Racks. As to the mowing it for Hay, that is a quite different Conſideration, and will be treated off in a diſtinct Chapter.

The Danger of Cattle being turned at random into freſh Clover is, that they will eat of it till they burſt. For this Reaſon it is beſt to feed them with it freſh mown, in proper Quantities

firſt,

firſt, that they may be a little uſed to it, before they are turned in to take their fill. The Novelty of the Taſte is one Thing that recommends it, and they are like Children in the Shop of a Grocer, whoſe only Danger is till they are uſed to the ſweet Things; after which they will not eat to hurt themſelves.

Some Conſideration muſt alſo be had as to the State of the Cattle, for ſome will bear a rich Nouriſhment better than others; and as for ſuch as ſeem to be moſt likely to receive Miſchief from it, the beſt Way is to give them Straw with it at firſt; and bring them to the rich Food alone by ſlow Degrees. This is an Article that will be better explained when we come to treat of the Diſorders of Cattle, and the natural Regulation of them in Point of Health.

When they are turned into the Field of Clover, it ſhould be done gradually; and this Rule holds good concerning thoſe which are well enough to be truſted in at once, as well as ſuch as muſt have this Preparation.

The right Method is firſt to turn them in about the Middle of a hot Day, when they have eat before, and the Leaves of the Clover are a little flagged. The great Danger of this Food is, when it is eaten in too great Quantities, and when the Dew is upon it; therefore Care being taken as to the Dryneſs of the Clover, the next Article is the not ſuffering them to eat too large a Quantity. They ſhould be ſuffered to be in the Clover but Half an Hour the firſt Day; the next Day they ſhould be turned in at the ſame Time, and left an Hour, and ſo on till they are accuſtomed to it: this we have obſerved generally before, ſpeaking of the Horſe and its Food, but it is proper to be more particular here.

Some Regard is to be had to the Weather in this Reſpect; for Experience ſhews, that Clover is very apt to damage Horſes in wet Weather, and much leſs ſo in dry. We have before ſpoke of the Danger of letting Horſes eat of it while the Dew is on the Leaves. Any wet with Clover makes it more dangerous than when dry, and it is from this that the Caution riſes.

It is alſo for the good of the Clover, as well as of the Cattle, to keep them off in wet Weather: their Feet are apt to do a great deal of Harm at any Time, but they will do moſt when the Ground is moſt damp.

The Addition of Ray Graſs to Clover is very advantageous in all Reſpects, and in none more than this of Health to the Cattle that feed upon it. This Ray Graſs is more of the Nature of the common and natural Graſs of our Paſtures, which is their proper Food; therefore being mixed with the other, it tends to correct its Richneſs; and, in ſome Degree, anſwers the Purpoſe of Straw, which we have ſaid is proper to be mixed with it. Then at the ſame Time that it renders it more wholeſome, it increaſes the Crop in Quantity, for this ſpreads under the Surface at the Root; whereas the Clover penetrates down deep, ſo that they grow as well together as the Corn and the Clover; and the Quantity is vaſtly increaſed upon the Ground; for the Leaves grow together as naturally and as well as the Roots, ſtanding no more in one another's Way than they do. The Clover ſpreads in an open looſe Manner, and its Branches ſhelter the Ground where the Roots of the Ray Graſs ſtand, ſo that it is moiſt and full of Nouriſhment; and, in the mean Time, the narrow ſlender Leaves of the Ray Graſs riſe up and appear through the Clover, without any Difficulty or Moleſtation. Both theſe grow together; and are fit to be mowed together for drying, or to eat together on the Ground: but there is this Caution to be given the Farmer, that Clover and Ray Graſs do not ſerve the Purpoſe of preparing the Land for Corn any Thing nearly ſo well as Clover alone. We have ſhewn how a Crop of Clover improves the Ground, which is, by ſheltering the ſuperficial Part, and drawing its Nouriſhment from ſome Depth; ſo that the upper Part, while it gets ſheltered, is unexhauſted: but this is only to be done by Clover alone, for Ray Graſs roots ſhallow as Corn does, and therefore the Ground is, in ſome Degree, exhauſted where the Corn is to get its Nouriſhment.

We do not ſpeak this ſo abſolutely as if Ray Graſs was never to be mixed with Clover, where Corn is intended to come afterwards. We give the Farmer his full Inſtructions, and he will know by this, that, in general, Clover alone is proper to be ſown where the Land is ſoon to bear Corn again; but, on the contrary, when it is intended to lie longer in Graſs, then Clover and Ray Graſs together. When Ray Graſs is mixed with Clover, where Corn is to follow ſoon, the Quantity of the Ray Graſs muſt be but ſmall; whereas when the Ground is to lie long in Graſs, the Quantity of the Ray Graſs ſhould be large. This is the whole Inſtruction in general Terms, and this the Farmer muſt, on every Occaſion, ſuit to his preſent Circumſtances and Situation.

Cows are ſubject to Diſorders from Clover as well as Horſes; and when it does not take this Effect, it injures their Milk in Flavour, and is prejudicial to the Productions of the Dairy. This Accident is alſo greatly abated by mixing Ray Graſs among the Clover in Sowing, for this being nearer the natural Provender of the Cow, takes leſs Effect upon her than with the other. The common Graſs of our Paſtures has frequently the wild Clover, we have named among it; ſo that there is no other Difference between a Field of Clover and Ray Graſs, and one of our common Paſtures, where there is a large Share of Honey-ſuckle Trefoil among the Graſs; but that the one is a Mixture of Graſs and Clover, in which the Graſs has the larger Proportion; and the other is a Mixture of the ſame Things, in which the Clover has the largeſt Part.

Clover, though it is a much more laſting Crop than any of the Pulſe Kind, which are ſown for the ſame Purpoſe of improving the Ground, yet is but of a certain Duration, and that not equal to Saintfoine, or ſome other of theſe artificial Graſſes. In general, Clover will laſt well enough three Years; but after that it declines ſo greatly, that it is not worth the continuing it upon the Ground. It is not that it

Pulses and Artificial Grasses.

Engrav'd for The Compleat Body of Husbandry Printing by the King's Authority, in Weekly Numbers, at 6d Each

will have exhauſted the Ground ſo, that it cannot be made to grow on it again without Culture, and due Preparation. Therefore the Farmer at the End of three Years, muſt, in the common Courſe of his Practice, plow up the Land again: if he deſign it for a different Crop, he will find it very well improved and fitted for it; if he intend to continue the Clover longer upon it, he muſt ſow a freſh Parcel of it after good Plowing, as he did the firſt, and it will ſtand three Years more very well in the ſame Manner.

We ſay the common Practice requires this; but it does not follow, that the Thing is in itſelf abſolutely neceſſary. For it might be much otherwiſe in another Manner of managing the Crop.

We have ſhewn that on certain Occaſions, common Graſs requires its Year of Reſt from the Scythe; and in the ſame Manner, if Clover on the third Year were not to be mowed, but only eaten, it is highly probable that it would recover itſelf ſo as to laſt longer. This I have ſeen tried where it anſwered moderately well, and the Soil was but indifferent; it is an Experiment very well worthy to be made, where there is better Ground; and the Farmer has the full Advantage. By what appears already, it ſeems very likely to anſwer well.

The Dutch, who ſave every Thing, were the Inventors of the Cuſtom of cutting the Clover green, and giving it to Cattle in the Racks, inſtead of turning them into the Field: and beſide its not ſubjecting them to Diſorders, there is a great deal of Frugality in this Management; and the Difference between thus uſing it green, and in the Hay are very great, for ſcarce any Thing loſes more in drying.

In thoſe Places where Clover was firſt given in this Way to the larger Cattle, it was diſcovered that Hogs are very fond of it: they were ſeen, and always are ſtill when they can get at it, feeding greedily upon the Refuſe that falls from the Racks. This led to the trying them with Clover; and it has been found a very excellent Food for them. Some have gone ſo far as to propoſe very extravagant Profits from this Uſe of Clover; but without believing ſuch Accounts, or truſting to ſuch Calculations too ſtrictly, there may be great Advantage in feeding them with it in a proper Manner.

The Benefit of feeding Cows on Clover would be much more regarded, were it not found to give a Taſte to the Milk; but the Farmer when he ſees an Inconvenience, is not to ſit down as if it could never be remedied. In this Caſe the Cure is very eaſy, it is only the not letting them feed entirely upon the Clover. Every Body knows that the natural Food of the Cow is the common Paſture Graſs; therefore as the Clover is not ſo natural, it ſhould not be given alone. When the Ray Graſs is mixed with Clover in the Sowing, the whole is more proper for Cows, than when the Clover is ſown ſingly; but, in either Caſe, the beſt Method is to feed them in Clover during the Day, and to turn them into a common Paſture of natural Graſs in the Night: this gives them a Mixture of the common with the richer Food, and their Milk, while it is rendered very abundant by the Uſe of the Clover, is kept to its common Taſte and Qualities by the other Graſs.

The Reaſon why Clover will not ſucceed ſo perfectly in the feeding of Hogs, in the Manner thoſe propoſe who have projected that Improvement is, that when they are turned looſe into a Field of it, according to that Propoſal, they deſtroy and taint it with their Dung and Urine, after which they will not eat it freely. This, beſide the Quantity they tread down, is ſo great a Diſadvantage, that I have ſeen frequently, where Hogs have fed plentifully, and throve extreamly upon it for a Time after they were put in, they have afterwards pined away, and grown miſerably poor. It is not that the Clover does not agree with them after a Time, but that they have ſpoiled it, and don't like it any longer in that Condition. 'Tis certain, that by feeding them with it properly, it would be an excellent Improvement upon the common Methods in that Reſpect.

Sheep are alſo fed very advantageouſly with Clover: they will eat it with equal Freedom freſh, and in the Condition of Hay; and it is of vaſt Service in the breeding up of Houſe Lambs, which, in the Neighbourhood of great Towns are ſo profitable an Article. The Ewes feed on it in Summer in the Field, and in Winter on the Hay under Cover; and there is no Food that ſupplies them with ſuch Plenty of Milk, or ſuch as is ſo fit for the nouriſhing the young.

The Farmer who manages with Prudence, will find this a vaſt Article in the feeding of his Horſes in Summer and in Winter; the Graſs and Hay being equally proper, under a right Management. And beſide the Advantage he receives from it in reſpect of his Ewes and Houſe Lambs, his Weather, Sheep, and Graſs Lambs will very well fatten upon it; and the Store Sheep may be ſupported on it during the Summer.

Theſe are ſuch important Articles in favour of Clover, that when they are named together, he muſt be a very poor Huſbandman who does not ſee the Advantage he will find in ſowing it.

Beſide the ſeveral Methods of Sowing it, which we have named alone, and with the different Corns; ſome have ſowed it with Peaſe, and others with Horſe Beans. In the firſt Caſe, the Peaſe are very apt to ſpoil the Clover; but there are Occaſions in which it is proper. The Beans, as they do not lie upon the Ground in the Manner of the Peaſe, are not liable to the ſame Objection; but then the Preparation of the Land for Beans being leſs than for Peaſe, and the Clover requiring a very well tilled Land, this does not ſucceed ſo well. When the Change of Crops renders it neceſſary, theſe Things may be done; and ſome Time may be ſaved by a Crop of Clover, in which the Ground otherwiſe would be idle; but theſe are accidental Conſiderations. The proper and profitable Methods are thoſe we directed in ſpeaking of that Article; either with Clover alone, with Ray Graſs in the common Method, with Barley or Oats, or with Wheat.

We have entered at large on the Uſe of Clover as it grows; we are now to conſider it in the Condition of Hay, with its ſeveral Uſes.

CHAP. XVI.

Of the mowing of Clover, and its Hay.

THE Farmer is to compute according to the ſeveral Circumſtances of his Stock, and his Ground; how far he ſhall want the Aſſiſtance of his Clover green, and how far in Hay. We have obſerved that the Mowing it every Year is a Practice which might occaſionally be let alone to Advantage; but the Growth is ſo ſtrong, that it may alſo, where Circumſtances ſuit, as they uſually do, be mowed more than once in the Year.

The firſt Time of Mowing is toward the End of MAY. The Root has been by this Time well ſtrengthened in the Ground, having ſtood through the Winter; and the Shoots are numerous and ſtrong. The Farmer is now to look well upon it for the proper Seaſon, for it is not in the Nature of theſe Things to allot any certain Day of the Month. It is a particular Condition of the Plant that gives it a Properneſs for Mowing, and this may happen according to the Soil, Seaſon, and many other Accidents forwarder one Year, and backwarder another; and earlier in one Crop, and later in another the ſame Year.

We have told the Farmer the latter End of MAY is the uſual Time of Clovers coming fit for cutting, and that it may be ſooner. He ſhould therefore begin to look upon it in the Middle of MAY; and obſerve in what Condition it is with Reſpect of flowering. As we have told him reſpecting common Graſs, we may add on this Head, that the Time when Clover is fitteſt to be cut for Hay, is juſt when it is getting into Flower, that being the Period of the Growth, in which the Leaves and Stalks of all Plants are fulleſt of Virtue. This we ſpeak of Clover with Reſpect to the cutting it in MAY or thereabouts, for Hay alone. There comes a farther Conſideration afterwards, when it is cut at a proper Time of the Year for Seed.

In this MAY or firſt Crop therefore, the Farmer is to conſult only the Richneſs of the Stalk and Leaf, and to find when that is at its greateſt Perfection, he is to examine the Heads with reſpect to their flowering.

The Flowers of Clover grow in ſmall Tufts, or roundiſh Heads, at the Tops of the Branches, and theſe appear there in form of roundiſh, green, hairy Buttons, ſome Time before the Flowers begin to open. The Farmer is to watch the Appearance of theſe, and to obſerve how they gradually come toward Ripeneſs; and he is to ſend in his Mowers juſt before they begin generally to blow. A few will make a Shew here and there in the Field, while the reſt are exactly in their right Condition; for there is no Plant in the World, a whole Field of which gets into flower all together. This is his Time for ſetting to work in Mowing, when all the Plants are full of Heads, and ſome few of them only have begun to open into Flowers. Let him perfectly comprehend the Reaſon of this Conduct; it is the more needful to explain it to him fully, becauſe ſeveral have erred in the Reſpect of letting the Clover ſtand too long for the firſt Mowing; and they think ſtill in many Places, they ought to ſee it in full Flower all over the Field before they begin.

The Intent of the Farmer here is, firſt, to get a Crop of rich Hay, and next to have his Clover Roots in a ſtrong and vigorous Condition; for their ſhooting quickly and ſtrongly afterwards, is a Thing of great Conſequence to him.

We have ſhewn that the Time when his Hay will be beſt of all, is when it is juſt getting into Flower, and this is a Time at which it has not exhauſted the Roots: this is a very material Conſideration. If it be cut juſt at that Period, the Roots are in full Vigour; and having loſt the large Head they had to ſupport, will puſh out their Shoots with a ſurprizing Strength; but if the Plant have been ſuffered to ſtand till all of it be in full Flower, and ſome getting into Seed, which happens very ſoon afterwards; then the Store of Nouriſhment that has been called up, has, in a great Degree, exhauſted the Roots, and they will grow very poorly afterwards for ſome Time.

Therefore as ſoon as all the Plants are knotted, or have the Heads formed at the End of their Branches, let the Crop be cut; and let the Mowers have Caution given them to cut it as even as poſſible, for this greatly forwards the Growth of the new Shoots. When cut, it is to be managed exactly in the ſame Manner as common Graſs, and ſo made into a dry, firm, and ſound Hay. The Farmer muſt not be ſurprized at his Clovers ſhrinking in the drying, for that it always does in a very particular Manner, its Branches falling together, and the Whole getting into a very ſmall Compaſs, compared to what it filled while growing.

Great Care is to be taken thoroughly to dry this, becauſe having a great deal of natural Moiſture, it will otherwiſe be very ready to become damp afterwards, and by that Means to decay. Being cut at this proper Growth, and carefully managed in the making, it will be an extreamly rich and wholeſome Food for the fattening all Kinds of Cattle. When it has ſtood too long upon the Ground before the firſt cutting, it not only impoveriſhes the Roots, but the Hay itſelf is too rank, and has not the excellent Qualities of this firſt Crop when made in Perfection.

After the mowing this Crop the Land is to reſt, and occaſionally it may be mowed again once, toward the End of Summer, or twice: the former Time in JULY, and the other toward Autumn. There may be Reaſons for cutting three Crops of Clover; for different Farms are ſituated and circumſtanced variouſly; but to ſpeak in general, it is not what the Farmer ought to make the Rule of his Practice. Very often when three Crops are cut, there is not Weather for making the

the laſt tolerably, for we have obſerved that the Clover requires good Weather, more than common Graſs, becauſe of its juicy Nature, which will eaſily contract Damage. At beſt, when the Seaſon favours moſt, the ſecond Crop impoveriſhes the third, and ſeldom gives it Time to ripen.

We have ſaid any particular Farmer's Affairs may make Variations from all general Rules neceſſary; but in the common Run of Things the Advice that is moſt profitably to be followed, is to make but two Crops of Clover Hay; and this is very material, when one of them is intended for getting of Seed, which is very proper: in this Caſe there requires a Time for the Crop to ripen thoroughly, which it will rarely do when two have been cut before.

We ſhall conſider the laſt Crop of Clover in the Summer, to be intended for Seed; and in this Caſe it muſt ſtand a good while. The Owner muſt look in upon it from time to time; and watch the Seaſon of its Seeds being ripe. He muſt wait for this with Patience; and he may wait without Fear, for this is not one of thoſe Crops, the Seeds of which are apt to ſhed.

If the Clover have been well managed, the Seeds will begin to appear in the Huſks toward the End of AUGUST, ſooner or later, according to the Soil, Seaſon, and Manner of ſowing: from this Time it will take between three Weeks and a Month to be thoroughly ripe: and when it is in that Condition the Stalk will begin to grow brown. This is the Caſe in all Plants, and this is the Time for mowing it on this Occaſion. When the Stalks are grown brown or yellow, and on opening the Huſks the Seed is found to be yellowiſh, the full Time of cutting it is come, then the Farmer is to take the Advantage of a good dry Day, and get it down. It is then to be made with Care into Hay, but this does not require all that Length of Time that a Crop does when the Stalks and Leaves are fuller of Juice. When dried it is to be laid up, and to be kept in the Straw in Spring.

Toward the latter End of MARCH it is to be carefully thraſhed and ſeparated from the Straw. After this the huſky Part is to be well dried in the Sun, and then thraſhed again; after this ſecond thraſhing it ſhould be ſpread for a farther drying, and then worked about with Rakes, and rubbed thoroughly in the Hands, and by this Means a great deal more Seed may be got out of it.

By the Difficulty that the Farmer will find in getting the Seed of Clover clean, he will learn not to be afraid of letting it ſtand in the Field till thoroughly ripe, for otherwiſe it will never ſeparate tolerably; and he may be ſure there is no great Fear of Waſte, in a Seed that is thus unwilling to leave the Huſk at any Rate.

Two Buſhels of good Seed will generally be had from an Acre of Clover, well managed and well threſhed: this is the niceſt Affair in all thraſhing, ſo that the Farmer muſt ſee to get a Perſon who underſtands it: ſuch a one will do four Times the Buſineſs of another.

The Difficulty of getting the Clover Seed clean from the Chaff, has induced ſome to prefer ſowing it in the Huſk, and there is no great Danger of its ſucceeding, provided it can be diſtributed properly on the Ground; but as the Wind is apt to have too much Power upon Clover Seed, in the common Way of ſowing it, when it is clean and free from the Huſk, it muſt neceſſarily have more this Way, and there will be danger of its blowing into Heaps in ſome Places, and leaving others vacant.

This Objection is only of Force againſt the common Way of ſowing; but where that is done by the Hand Drill, as we have adviſed in the ſowing Clover with Barley, it may as well be uſed Huſk and all; for it may be laid in with the ſame Regularity as if naked.

The Seed of Clover the firſt Year is better than any other, but it will grow very well the ſecond; after this it is hazardous truſting it, a great deal of the Seed miſcarrying.

CHAP. XVII.

Of the Soil for Saintfoin, and its Growth.

IN the Part of this Work regarding the Drill and Horſehoeing Method of Huſbandry, we gave an Account of Saintfoin, as an Inſtance of one of the Crops to which that Practice is ſuited; having therefore occaſionally and neceſſarily given an Account of the Nature of the Plant there, we ſhall not repeat it in this Place, but conſider the Advantages of that Crop, and its Method of Culture according to the uſual Ways of Huſbandry.

Two Articles give Saintfoin the Preference againſt Clover; theſe are, its larger Size and its longer Continuance in the Ground. Clover, we have ſhewn, laſts properly but three Years, Saintfoin will laſt four Times as long; or more than that if neceſſary. In order to keep Clover a little longer upon the Ground without freſh ſowing, the ſecond Crop muſt be given up as to mowing; it muſt ſtand to Seed after the firſt Crop: and when the Seeds have ſcattered themſelves, Sheep muſt be turned in to feed upon it. This is a Method attended with evident Diſadvantages, and is often inconvenient: Saintfoin requires no ſuch Management: let a Ground be once well covered with it, and it will take Care of itſelf afterwards; when it is thought fit to plow up the Land, Corn thrives excellently upon it: the Method of doing this, we have ſhewn already, in ſpeaking of the various Methods of Tillage.

As to the Soil proper for Saintfoin, any thing will do except Chalk; this it naturally abhors, but on very poor, ſtony, and ſandy Grounds it will do very well: and though a Plant that naturally roots very deep, yet it will thrive where the Mould is but ſhallow: its deep rooting is a great Advantage where there is Compaſs for it; for this makes the Leaves of Saintfoin look freſh, and ſerve excellently for the Cattle, when all others are parched with a Drought in hot Summers. The Sun can take no Effect upon a Root that goes ſo deep; and it always finds Nouriſhment there, while the ſuperficial Mould in which Clover, and ſuch other Things are rooted, is ſcorched and dried up.

Saintfoin is an excellent Crop any where, but

it will anſwer the Farmer's Purpoſe beſt of all in thoſe Places where Manure is ſcarce: it may therefore be conſidered as one of the beſt Crops the Farmers in the remote Countries can take into their Hands. They need not be afraid of a ſtony Bottom under the ſhallow Mould in theſe Places, as that is a common Condition of much of the Land there, for the Saintfoin will puſh its Roots through the Cracks that there always are in Beds of Stone near the Surface, and by that Means find Nouriſhment lower, where one would not ſuppoſe the Roots of any Plant could reach.

CHAP. XVIII.

Of ſowing Saintfoin, and managing it while on the Ground.

SAintfoin ſo far partakes of the Nature of Clover, in Reſpect of the Farmer's Concern, that it may be ſown either alone or with Corn; or it may be ſown entire, or with a Mixture of Ray Graſs. But this latter Method is not of that Advantage that is in the Caſe of Clover, for Saintfoin is very well able to fill a Land alone, and it has not the Inconveniences that attend Clover, in diſordering the Cattle which feed upon it.

The moſt uſual Way among our Farmers at preſent is, to ſow Saintfoin with Barley, and this in the common Method of Huſbandry, is a very ſucceſsful Practice. The Method of doing it moſt advantageouſly is this, let the Ground be plowed three Times, to get it into a very fine Condition; for as Clover requires this, in order to produce a tolerable Crop, Saintfoin renders it more neceſſary; and it is very well worth while, becauſe of the long Time this will laſt.

The Land being well broken by Tillage, ſhould be manured with mellow Dung, or ſome of the richer Kinds in a ſmall Quantity, as Soot, than which nothing is better. This done the Barley is to be ſown, and after it is harrowed in the Saintfoin is to be ſown by the broad Caſt-way. But let the Perſon who does it have a Caution given him, to ſcatter the Seed very thin, and ſow it twice in a Place. This is the only Way of raiſing a Crop of Saintfoin according to the common Methods, with any tolerable Degree of Regularity. When ſown, the Ground is to be harrowed lightly over, and nothing more is to be done till the Time of rolling the Barley, which is alſo of great Uſe to the Saintfoin.

Thoſe who ſow Saintfoin with Oats muſt uſe the ſame general Method as with Barley, but the former is always the better.

Saintfoin may be ſown alone in Spring; but that is not the beſt Practice. It may as well be got into the Ground the October before, and by this Means there will be a Crop of it a Year ſooner than there would be in the common Way. The Choice of the Seed depends upon the ſame Particulars as that of Clover, it ſhould be clean, heavy, dry, and of a ſhining Surface. The freer from Huſks the better.

The Difference in Reſpect of the Quantity of Seed to be allowed in this, and in the Drill Huſbandry, is very conſiderable: five or ſix Buſhels are commonly allowed in this Way of the broad Caſt ſowing, to an Acre, and leſs than four is not ſufficient; the other is rather too much. When Ray Graſs is ſown with Saintfoin, the general Proportion is five Buſhels of Saintfoin Seed, and one Buſhel of the Ray Graſs to the Acre.

When Saintfoin is ſown alone, if the Weather be dry at the Time of its firſt coming up, 'tis very apt to take a Stint in the Growth, from which it is a long Time recovering; this may be prevented by watering it by Means of a Cart, with a Convenience behind pierced with Holes. In the new Method of Huſbandry this would be eaſy; but it has been practiſed in the common Way with very good Succeſs.

When Saintfoin is ſown in Spring with Barley or Oats, the ſooner it is got into the Ground the better; and in general it ſucceeds much the beſt when ſown alone in Autumn. The dry Weather that is ſo prejudicial to its Growth is not to be expected at that Seaſon.

In a ſucceeding Chapter we ſhall treat of mowing Saintfoin for Hay; but here we are to conſider the beſt Method of feeding of Cattle upon it while on the Ground. This is a very profitable Practice, but it requires ſome Management. The Cattle are not ſo apt to hurt themſelves with this as with Clover, but they may very eaſily damage the Crop; and when the Farmer finds that it is one of thoſe Crops calculated for laſting ſeveral Years, he will underſtand that it is worth while to guard againſt ſuch Accidents.

In order to his underſtanding how to do this beſt, he muſt acquaint himſelf with the Nature of the Plant. Saintfoin is very ſtrong and hardy, and is not eaſily injured when it is well eſtabliſhed in the Ground; but at firſt it is very eaſily; eſpecially at the Top of the Root, where the Damage is not readily recovered.

For this Reaſon let the prudent Farmer be tender of his Saintfoin the firſt Year. The moſt likely Methods of hurting it would be the putting large Cattle into the Ground while the Plant is very young, for its Sweetneſs will tempt them to eat it down cloſe, and by that Means hurt the Head of the Root; and at the ſame Time their Feet would increaſe the Miſchief by treading of it down.

Therefore if the Farmer finds it needful to put any of his Cattle into a Saintfoin Ground the firſt Year, Sheep are the moſt profitable; but it is beſt to omit this entirely.

The moſt beneficial Method of managing Saintfoin is to mow it the firſt Year, cautioning the Scythemen to be very regular in their Work, and not to come too cloſe to the Root: the next Year Sheep may very well be fed upon it; and after this it will have got ſo much Strength that it may, without Hazard, be uſed according to the Farmer's Circumſtances and Diſcretion in feeding and mowing.

We have named twelve Years as a Time during which Saintfoin continues very good and ſtrong; but in this all that is to be done is ſpeaking generally and in round Numbers, for according to the Nature of the Ground, and the Uſage

the Crop has received, it will in ſome Places be worn out ſooner, and in ſome it will laſt twice that Time.

When worn out it may be plowed up and ſown again, or another Piece of Ground found for that Purpoſe, and Corn ſown on this; but it may alſo be refreſhed by Manures: of theſe none anſwers the Purpoſe ſo excellently as Marle. A tolerable Quantity of this ſpread over a decaying Piece of Saintfoin, will refreſh it for ſeveral Years; and there are Circumſtances of Affairs under which this may be very well worth while. Very rotten Dung may be uſed for the ſame Purpoſe, or Soot; but nothing anſwers ſo well as Marle.

The feeding upon the Saintfoin Ground is an excellent Thing for Cattle: it is full of a rich Nouriſhment, and yet not rank. It fattens them, without breeding Diſorders. Spring is the Seaſon when it beſt anſwers this Purpoſe, and this is moſt convenient to the Farmer: the only Caution he need have in this Reſpect, is not to put heavy Cattle upon it in wet Weather: in any other Seaſon, when the Crop is well eſtabliſhed, they will not be able to hurt it; but their Feet in ſuch Weather will do ſome Damage; and the ſucceeding Crop of Hay may eaſily ſuffer more from this, than from all their feeding.

As the Spring is the beſt Seaſon for feeding large Cattle upon it, the Autumn and Winter are the moſt proper for Sheep: this alſo very well anſwers the Farmer's Purpoſe, who contrives accordingly. The great Shoot of the Spring is ſufficient for the Cows and Oxen, and the Crop recovers itſelf ſufficiently for one mowing, after which there grows a young Shoot that ſerves very well for Sheep, at a Time when they want it; and they neither damage it by their cloſe eating, nor by their heavy treading. No Food fattens Sheep ſo freely or ſo ſuddenly at that Seaſon, and none is better for Oxen in Spring, or for Milch Cows, when eaten upon the Ground, or Green in the Rack: it cauſes Abundance of Milk, and does not give it that ſtrong and particular Flavour it has from the feeding on Clover.

The general Cautions we have given muſt be enlarged or retrenched, according to the Soil and other Accidents attending the Crop. In a dry Soil and dry Seaſon large Cattle may be turned in upon the growing Crop, earlier than we have ſaid; and on the contrary, in a moiſt Soil they muſt be kept out later. Nothing eſtabliſhes itſelf more firmly in the Ground than Saintfoin, giving it Time; but when it is trampled upon young, in a damp Ground and wet Seaſon, it is damaged in ſuch a Manner, as often never to recover it thoroughly.

CHAP. XIX.

Of mowing of Saintfoin, and the Uſes of its Hay.

WE have now to mention the ſecond Condition of Saintfoin that is in the Form of Hay, and in this it is not at all leſs valuable than in the firſt. If freſh Saintfoin be excellent for the horned Cattle, the Hay of it is one of the beſt known Foods for Horſes; nor is it confined in its Uſe to them. There is a particular Management required in keeping the Ground for Hay, but it is ſo like that uſed for Clover, and indeed for natural Graſs, that the Farmer who is unaccuſtomed to this excellent Kind will need very few Words to explain it.

In order to have a Crop of Hay of any Species, the Ground muſt be laid up a proper Time for that Purpoſe. The Time for laying up Saintfoin for this End is toward the latter Part of MARCH, and from that Time two Months will bring it into a Condition for mowing to great Advantage.

Saintfoin is to be mowed like Clover juſt when it gets to Flower, with this Difference, that the Saintfoin may be allowed to ſtand till a little forward in Bloom, but it muſt not be ſuffered to remain till the Bloom begins to fade, and the Seeds to be formed. In Clover the greateſt Benefit riſes from cutting it juſt when the Heads are all formed for flowering, and but few of them have opened; in Saintfoin the exact Time is when a good Number of the Flowers have opened, but none are fallen.

It is then to be mowed and made into Hay, by frequent and careful turning: it requires more Care and Pains than common Hay, but not ſo much as Clover, the Leaves and Stalks not being ſo juicy.

The propagating Saintfoin for the Service of its Hay, is a Thing of the greateſt Importance to the Farmers, in many of our Corn Countries, for the Nature of the Land in many Places is throughout very ill adapted to Paſturage; and the Profits from Corn are ſo great, that very little is uſed for that Purpoſe in others. In ſome Places this is carried to ſuch a Height, that there are large Farms in thoſe Parts of the Kingdom that have ſome very little, and others no Land of the common Paſture Kind, ſo that the People who occupy them can ſcarce keep any Cows in moſt, and in ſome find it very difficult and expenſive to ſupport their Horſes. In this Caſe the introducing of Saintfoin muſt be a Thing of great Convenience, it is bringing in a Crop that will be managed with Eaſe in their own Way, and will grow on the common Run of their Grounds, and will come in the natural Courſe of their Tillage; and this will feed their Horſes and other Cattle, and if they chuſe to cultivate more of it will bring them a great Profit at the Market.

A Field of Saintfoin will, in ſuch a Caſe, make a prodigious Change in the Farmer's Affairs. He may feed Cows, if he have Ground near Home, with the freſh cut Saintfoin during the whole Summer, under Cover in Racks; and in Autumn and Winter he may turn them in to the Aftermath of it, only obſerving the Cautions we have given him to favour the Ground in wet Weather. When the Winter is advanced he may turn in his Sheep; and then feed the Cows under Cover again, with the Hay cut at the MIDSUMMER mowing, and in Spring turn them into the freſh Growth of it again. This is a prodigious Thing in Counties where natural Graſs is

ſcarce; the Farmer in theſe Places uſed to be confined to the ſingle Article of his Buſineſs reſpecting Tillage, and the Growth of Corn; but by the introducing of this Plant, he is able to undertake the Whole, and ſhare the Advantages of thoſe more happily ſituated, part of whoſe Land falls out naturally for Paſturage, part for Corn; and who find it eaſy to keep up ſuch a Proportion, as makes them mutually ſubſervient to one another.

CHAP. XX.

Of Lucerne, its Soil, and the Manner of ſowing it.

LUCERNE, or as the French call it, La Lucerne, is one of thoſe Plants which we have introduced like the Saintfoin from Abroad, into the Practice of the British Huſbandry.

It is one of thoſe Species which happily ſerve in the Place of natural Graſs, and are therefore called artificial ones. We have ſaid the leſs of Saintfoin in this Place, becauſe it had been treated of before on another Occaſion. Lucerne having not been mentioned yet, we are to conſider it here at large.

It is a pretty looking Plant, with blue Flowers. The Root is very long, and of a conſiderable Thickneſs. The Stalks are firm, upright, and branched; they have great Numbers of Leaves growing three on each Foot-ſtalk; and the Flowers ſtand in little Heads, followed by a Kind of twiſted Pods.

It anſwers the Purpoſes of Saintfoin to the Farmer, and, like that, endures in a ſerviceable Condition many Years.

Lucerne has been long known in Huſbandry, and at all Times very famous; we had it from France; but the Romans in antient Time have written greatly of it; and by the Labour and Expence they employed in its Culture, it is plain they were acquainted with its Value. They called it Medica, and we find frequent mention of it in all their Poets, as well as Proſe Writers, who treat of Agriculture. They preferred it before all other Plants as a Fodder for their Cattle; and by what Experience ſhews thoſe who have raiſed it here, of its Effects, they had Reaſon: it is certain nothing excels, and perhaps it would not be too much to ſay, nothing equals it; with this Character, which is vouched by the Experience of all Huſbandmen in other Countries, and in no Part contradicted by the Trials that have been made of it in England, we hope it will become more known, and in ſome Time univerſal.

We have in the laſt Chapter ſhewn the great and particular Benefit there is in Saintfoin, and there is the ſame or more in this. The Antients have left us Things concerning its Effects in fattening of Cattle, hardly to be credited; but the Account the French, among whom it is more commonly cultivated, give of it, and what I have ſeen of ſome raiſed in England, ſeem to give Reaſon to believe thoſe Relations are not much exaggerated.

It is ſweeter than Clover, or even Saintfoin; and has ſo many known Advantages, and ſo few Objections have been raiſed againſt it, that the only Reaſon why it has not been more generally introduced among us ſeems to be, that its Culture is not ſufficiently underſtood. In this, however, there is nothing very difficult; and we ſhall lay down a Method ſupported by ſome Experience, which will lead the Huſbandman to all its Advantages without any Hazard of its failing.

With Reſpect of Soil, Lucerne will grow on any. This is a Recommendation of the moſt important Kind, becauſe it puts it into every Farmer's Power to raiſe it. Tho' it will live on any, it will thrive beſt on the richeſt; but there is none where it will not be of equal Benefit with any other Crop it would afford.

The Antients were ſo ſenſible of its Value, that they gave it the beſt natural Soils they had; they improved theſe with all poſſible Care by Manure, and by Tillage: there is no Crop for which we dreſs the Ground in nearly ſo laborious, or nearly ſo expenſive a Manner; and it is beyond a Doubt, that if we would follow their Example in taking a great deal of Care of it, and beſtowing, if not ſo much as they did, yet a ſufficient Expence and Labour upon it, we ſhould reap proportionable Advantages.

We can perceive that with all their Expence, they had not the right Knowledge of its moſt advantageous Culture; they always ſowed it thick, which, by what we ſee in Experience, muſt have had a very bad Effect.

The Root of Lucerne being large, is enabled to ſupport a large Head of numerous Stalks; and this is the Method by which it will be moſt ſerviceable to the Farmer. Now this can only be promoted by its ſtanding at a Diſtance one Plant from another. On this depend the great Profits ariſing from Lucerne, and this the Antients had not; nor can we have, in the common Method wherein it is propagated here; for all our Farmers that have tried, have run into the ſame Fault with the Antients: they have all ſown it ſo thick, that the Plants have ſtarved one another; and inſtead of a Field covered with a due Number of flouriſhing and vigorous Heads of it, they have continually an innumerable Multitude of ſmall poor ones.

For this Reaſon it is eaſy to ſee, that the Drill and Horſehoeing Method muſt be fitter for this than for the common Method; becauſe that Way the Plants will ſtand remote, and they will be vigorous: this will alſo be farther promoted by the Horſehoeing, in a manner which it can be no Way elſe. It is to theſe deep rooted Plants, that Method of Culture is moſt particularly adapted. They ſpread at a Depth under the Ground by Means of very large and numerous Fibres; and the deep Plowing between the Rows by this Practice, breaks the Earth about them while growing, which can never be done any Way elſe.

We know by all Experience, the Benefit of breaking and dividing the Ground while Plants are in it, and by this Means it can be done at Times during all thoſe Years the Lucerne ſtands upon the Ground; and will always have its Effect.

The keeping a Crop of Lucerne in this vigorous Condition, is of more Benefit than in any other Caſe. It is in a Manner particular to this Plant, that as ſoon as mowed, it ſends up new Shoots in Abundance, from the Boſoms of all the Leaves; that is, the Place where they join the Stalks; and from the Part juſt below, where the Scythe cut off the Top: theſe are much more quick in Appearance, and more numerous than in any other Field Plant, and they furniſh an immediate ſecond Crop.

This, tho' an Accident in Nature, is yet greatly to be promoted or retarded by the Growth of the Plant in a more or leſs vigorous Manner; and this will depend upon its Diſtance, and its Manner of Culture. In the common Method of Huſbandry it is too cloſe to be well nouriſhed naturally, and there is no Poſſibility of Arts comeing in to its Aſſiſtance: in the other Method, the Plants ſtand clear, and the Hoe Plough ſupplies them continually with new Stores of Food: therefore in this Way, the ſhooting of a new Crop will be almoſt inſtantaneous. The FRENCH have introduced this Method of Huſbandry into their Fields of Lucerne, from the Writings of Mr. TULL, our Countryman; and they boaſt of its Succeſs. It is a Reproach to us that others have the Advantage of Labours undertaken in vain for our Service.

It is from this ſudden and ſtrong ſhooting from the old Stalks, that the Lucerne yields ſo many Crops, we ſee Clover will very indifferently afford them; two is all it can be made to give with full Advantage; and from Saintfoin, the beſt Practice is to take but one a Year. On the contrary, the Lucerne yields at this Time ſeven Crops a Year in the South of FRANCE, and all large ones; and in other Places where it is cultivated, five or ſix according to the Advantage or Diſadvantage of Seaſon or Situation: in ENGLAND we may, by the Horſehoeing Huſbandry, render it capable of producing more than will be eaſily credited by thoſe who have not Experience of the Nature of this Plant, and the Effect of that Cultivation.

It is no wonder that in ENGLAND this Plant has not hitherto ſucceeded to the full Effect whereof it is capable; becauſe the very Advantages of our Soil and Climate, when proper Care is not taken, otherwiſe make againſt it.

Wherever Lucerne is planted, the greateſt Danger that can attend it, is the Growth of common Graſs amongſt it. The Lucerne always declines as this advances; and by that Time it comes to ſpread and turf, the Crop will be good for nothing.

There is no Country where Graſs is more univerſal, or where it turfs ſooner than in ENGLAND; therefore no Place where a Crop of Lucerne would be likely to be ſo ſoon over-run and deſtroyed; but then by the Drill and Horſehoeing Huſbandry, it is very eaſy to prevent this Accident; and then that Moiſture of the Ground, and mild Temperatnre of the Air, which would encourage the Graſs, will alſo very happily forward the Growth of the Crop.

The good Crops of Lucerne in FRANCE and ITALY, are, in a great Meaſure, owing to the Sun drying up the natural Graſs: when there happen any conſiderable Rains there in Summer, the Crop is poor; with us therefore there never could be expected a good one, if we could not prevent this Accident, but it is plain by the Horſehoeing Huſbandry we may. In the Endeavours that have been hitherto made to raiſe it, People knowing the Danger to which it was liable from the Growth of the Graſs, have ſowed it thick, that it might ſtarve the Graſs that ſhould attempt to riſe among it. The Antients followed the ſame Practice, and gave the ſame Reaſon for it: with them the Error was not of ſo bad Conſequence, becauſe they prepared their Land ſo richly; but with us it is always deſtructive, for its ſtarves itſelf when ſown thus thick; and being ſtarved, the Graſs grows more eaſily among it.

We have ſeen many Trials made in this Manner, and all unſucceſsfully: the natural Graſs has grown up among the Crop, and continually gathered Strength; and the other has proportionably declined; till in a very few Seaſons a Paſture of Lucerne has been changed into one of common Graſs, with only juſt as much of the Lucerne as would ſerve to ſhew it once grew there. As the Lucerne draws its Nouriſhment deep, the upper Part of the Ground will always ſupport Graſs; and in ENGLAND, wherever Graſs can be ſupported, it will grow; and wherever it grows among Lucerne, it deſtroys the Crop. Nothing but the breaking up the Ground about it, while growing, can prevent this Accident; and no Method of Culture, but that by the Drill and Horſehoe, admit this: it is very plain to Reaſon therefore, not only that this Method will ſuit Lucerne better than any other, but that it never can be raiſed advantageouſly in ENGLAND any Way elſe.

In FRANCE and ITALY they plow between the Rows, where it is leſs needful: there is double Reaſon why we ſhould do it here. In thoſe Countries it ſerves but one Purpoſe, which is breaking and dividing the Ground to ſupply the Plants with Nouriſhment; but with us it will anſwer two, and thoſe equally important; the giving Nouriſhment to the Plants, and deſtroying the Graſs.

The Seaſons in ENGLAND, when this Crop is properly managed, favour it even under the ſame Condition in which they hurt it in thoſe Countries where it is moſt propagated: our hotteſt and dryeſt Summers will never damage it, when cultivated by the Horſehoeing Huſbandry; for the Wet will ſupply it with Nouriſhment, which the Earth broken by the Hoe, will be ready to detain for its Service; and the Heat of our warmeſt Weather will only be ſerviceable to it; and it will find Food in the drieſt, when the Ground is open, as it is thus made to the Reception of the Dew.

As to the Cold of our Winters, that is not to be feared; becauſe Experience ſhews us, that Lucerne will live and thrive where many of the Garden Plants, that ſtand the Winter with us, periſh: ſo that if it can bear a colder Winter than our own, it will be ſafe from Injuries in ours; and from this, and all other Conſiderations taken ſeparately firſt, and afterwards together, there is Reaſon to believe that ENGLAND

is a Country where this Plant may be raiſed as advantageouſly, as in any upon the Earth: there only requires a proper Method of Culture, and that Method is the Horſehoeing Huſbandry, which has been long practiſed elſewhere; and which Mr. Tull, from the Succeſs he ſaw attend it in other Countries, brought into England.

CHAP. XXI.

Of the meſt proper Soils for Lucerne.

LUCERNE we have obſerved, will grow on a poor or rich Land: the Romans of old gave it the richeſt Soils they had, and improved them moſt; and at preſent we ſee it grow very well in France upon ſome very poor ones, with no great Expence of Culture, but under the Advantage of the Horſehoe: what there is in the Ground moſt favourable to it is Warmth, and a due Depth; what is moſt injurious is a bad Bottom: it is eaſy to conceive, that a Plant which roots ſo deep, is affected by what lies below the Surface; and this has been the Reaſon why it has failed in ſome Parts of England, where its great Deſtroyer, the Graſs, has not been very troubleſome. I have ſeen tolerable Care uſed about it, and yet it has not throve; and, upon examining, have found under the Soil a Bed of tough Clay: this is an Under-ſtratum very diſadvantageous to many Growths, but to none ſo much as to Lucerne; for it detains Water about the Roots, and at the ſame Time chills it; ſo that many of the Plants die, and the reſt dwindle away.

A ſevere Winter will deſtroy a Field of Lucerne which has this Diſadvantage, while one that is not under this Check, ſhall not loſe a Plant.

As Lucerne is a Native of a warmer Climate than ours, we ſhould give it our warmeſt Soils. A very good Loam, with a large Portion of Sand, and of mellow Earth among it, and with very little Clay, is the moſt favourable Soil of all for us: next to this may be accounted that dry crumbly Earth we have in many Parts of Buckinghamshire, which is a Compoſition of mellow Earth and Sand; after this a warm, and not over-barren Gravel is to be preferred; and, laſtly, any ſandy Soil that has ſome Degree of Richneſs; for it will not proſper in abſolute Sand.

Of all theſe Soils the gravelly is found to ſucceed beſt, in the particular Effect of ripening the Seed of Lucerne; and, in general, ſuch Places as are too moiſt from frequent little Springs are worſt, though their Soil be ever ſo favourable.

This is an Article in which we ſee a great deal of Difference with Reſpect of Climate, too much Water is deſtructive of this Plant in England; whereas in France and Italy, it never ſucceeds ſo well as when near the Banks of Rivers and Springs; but there the Heats are greater, and it therefore requires more of that Refreſhment. Though we do not recommend that tedious and expenſive Method of Culture, which was given to Lucerne of old; yet we ſhall adviſe the Farmer who intends to plant it on a poor Soil, to enrich it according to its Nature, with any of the Manures moſt agreeable to its Kind. Of theſe we have treated in their proper Place. He ſhould thus prepare the Ground for the Plants; and when they are on it, he may, if he pleaſe, occaſionally refreſh them with a little more.

This Doctrine is not agreeable to the Syſtem of thoſe who would have the Uſe of the Hoe Plow ſuperſede that of Dung. We have ſaid already, that no Method of Culture anſwers ſo well as this for Lucerne, nor indeed can it be raiſed beneficially by any other Method in England; but we adviſe the aſſiſting this Practice with Manures for the Sake of frequent Crops, theſe depending upon the quick Growth of the Shoot after Mowing.

CHAP. XXII.

Of the ſowing of Lucerne, and managing it in the Ground.

THE Antients, after their great Preparation of the Land, ſowed their Lucerne in the Beginning of April; at preſent they have two Seaſons for it, both in Italy and France; the firſt is in March, the latter in October. The Romans erred in ſowing it ſo very late in the Spring, becauſe there wanted Rains, and they were obliged to water it: the preſent Practice in thoſe Countries is better; and, in general, the October ſowing is the moſt profitable; the Plants having Time to root themſelves well in the Winter, and the wet Seaſon aſſiſting them greatly in their firſt Shoots.

The Difference of Climates is ſo great, that it would be very prejudicial to attempt introducing the Methods of Huſbandry from Italy into England in the ſame Form: it is very proper for our Farmers to know them, that they may perceive on what their Succeſs depends; but they muſt be here accommodated to the Climate. If we ſow Lucerne in Autumn, it will lie in ſome Danger from the Winter. However, the Farmer knowing this, may, if he pleaſes, ſtand the Hazard. Young Lucerne will be deſtroyed by thoſe Winters which will not affect it in a more eſtabliſhed Growth; and in the ſame Manner afterwards, a Field of it that is ill managed, and poor, may be hurt, when one that is in better Condition eſcapes. As to the October ſowing, the Chance is this; if the Winter be ſevere, and the Soil unfavourable, the Crop may be loſt; if it ſhould prove mild, and the Soil agreeable, the Lucerne will ſtand; and it will have got ſuch Strength, that it will make much better Head early in the ſucceeding Summer.

As we ſhall not lead the Farmer into Hazards, in the Culture of a Plant we want to introduce more generally into this Country, we ſhall adviſe him not to think of the October ſowing, but to limit himſelf entirely to the Spring,

Spring, and to wait till very late in that Seaſon, that the Danger of the Froſts may be over.

We have blamed the Huſbandmen of Italy, for deferring their Spring Sowing of Lucerne till April; but we ſhall recommend that very Practice to the English, and adviſe the defering it here till toward the Middle of that Month.

The ſowing it earlier, may, in ſome Years, ſucceed better; but this depends upon the Accidents of the Seaſon, and we would not have the Farmer liable too much to them in a new Undertaking. If it ſhould be ſown in March, and a mild dry Time follow, it would be better than later; but of this no-body can be ſure: and, in other Caſes, the Expectation of a Crop are eaſily deſtroyed two Ways; for if a great deal of Wet ſhould come ſoon after Sowing, it will rot the Seeds in the Ground; and if Froſts of any Power follow the Time of its coming up, they will utterly deſtroy the Crop.

The Quantity of Seed to be allowed to an Acre, is a Thing to be determined by Experience; but the Way of ſowing it by the broad Caſt, which has been the Cuſtom in moſt Parts of England where this Plant has been tried, is by no Means proper on any Account; and a vaſtly larger Quantity of Seed than needful has always been allowed. The Method we propoſe by the Drill, will eaſily determine the needful Quantity of the Seed. The Plants ſhould ſtand at about ſeven Inches Diſtance in Rows, and theſe Rows ſhould be at a Yard diſtant one from another. It will be poſſible to work the Horſehoe in theſe, and the Plants will be perfectly well ſupplied with Nouriſhment. The Farmer need not be afraid of having by this Method, a ſufficient Quantity of Plants upon the Ground; for each of theſe, if rightly managed, will, when grown to Perfection, have from a Hundred to more than two Hundred Stalks.

When the Lucerne is ſowed thin in Drills at a Yard Diſtance, in the Middle of April, upon a proper Soil well broke for that Purpoſe, the Moiſture and Warmth of the Seaſon will ſoon bring it up. As ſoon as it has got a little Height, the Farmer is to ſend in ſome Hand Hoers, with Inſtructions how to work. They are to hoe up the young Growth of Weeds that have riſen about the Rows on each Side, and to thin the Plants where they have come up too thick, leaving the moſt promiſing at the Rate of about four in every two Foot. They are not to thin theſe to exactly ſix Inches Diſtance each, but to preſerve the beſt Plants in about that Number. Theſe Hand Hoers are not to meddle with the Middle of the Intervals, but only to deſtroy the Weeds, and break the Surface of the Ground juſt about the Rows.

This done, the Plants are to be left to themſelves till they are of ſome Stature, and the Intervals are over-run with Weeds. Then the Hoe Plow is to be ſent in, and a tolerably deep Furrow is to be turned in the Centre of each Interval.

This is to be repeated as often as the Weeds appear, only leaving here and there an Interval free and unplowed for the Convenience of makeing the Hay.

The Intervals that are left at one Time may be plowed up at another; but in that Caſe there muſt be a Number made ſmooth by Rolling at proper Diſtances.

By this Management Lucerne will thrive very well till Graſs begins to grow among it, which it is always apt to do, and always as we have ſeen to the Deſtruction of the Crop.

In this Caſe there muſt be a good Furrow plowed from each Side of every Row; and afterwards there muſt be Harrows brought in to the Ground, and drawn croſswiſe; theſe, without injuring the Crop, will tear away the Graſs which the Plow raiſed, and ſuch as grow among the Plants; after this, the two Furrows firſt plowed up, beſide each Row, are to be turned again upon them; and there will be the double Advantage of clearing away the Graſs, and giveing the Roots of the Crop a fine Quantity of freſh Earth for their Nouriſhment.

The Graſs that was left upon the Ground, and half killed by the Sun, will be thus buried and thoroughly deſtroyed; and after this it will not be able to make any Head again for a great while.

As to the thinning of Plants in the Rows by the Hand Hoe, it muſt not be done till they have got ſome Strength, for fear of Accidents. The Sweetneſs of the Lucerne Leaf, when very young, makes it liable to the ſame Damage by the Fly as Turnips, therefore it is proper to ſee that Danger over before it is thinned; for when the Plants have got ſome Strength, this Inſect never attempts them.

As to the Horſehoeing afterwards, it is to be repeated oftener than to any other Species whatſoever, for this plain Reaſon, that it is to forward ſo great a Number of Crops. Thoſe who have hitherto raiſed Lucerne in England, following the common Method of Huſbandry, have contented themſelves with two Crops a Year: but we ſee what it yields in other Countries, and by the ſame Management we may bring it nearly, if not altogether to the ſame Richneſs here.

If the Farmer ſhould at any Time have neglected his Lucerne, ſo as that the natural Graſs ſhould become a Turf, and the Plants appear, as in that Caſe they certainly will, in a decaying State; the four coultered Plow is then the Inſtrument for his Purpoſe.

This we have deſcribed in its Place, and ſhewn in what Manner it breaks and tears a Turf to Pieces, be it ever ſo tough and thick: with this he is to go round every Row, turning the Furrows toward one Row, and from the next, the firſt Time; and the next, from the Rows they were turned toward before, and to the others: thus taking Care not to hurt the Plants by letting the Furrows lie too long upon them, the Graſs will be deſtroyed, and the Plants will recover.

In this Caſe there muſt be ſome Intervals left as in the common Courſe for the making of the Hay; and by this Practice there will be found no Difficulty of making this moſt valuable Plant ſucceed perfectly well in England, and afford its numerous Crops as in other Countries.

CHAP. XXIII.

Of the Value of Lucern, and Manner of uſing it.

THE Superiority Lucerne has over all other of the artificial Graſſes, is in the Frequency of its Crop; this gives it a Value to the Farmer which none of the others have; and it is encreaſed by its natural Richneſs, and wholeſome Qualities.

The others are to be uſed partly by cutting, and giving them green in the Racks, partly by drying into Hay, and partly by feeding on the Ground; Lucerne would equally anſwer all theſe Purpoſes, but it is better to ſpare the laſt, for the Feet of large Cattle would tread it down in ſuch a Manner, that the Owner would loſe much more in his ſucceeding Crops, than would equal the Advantage of that Feeding. In the other two Methods it anſwers excellently, and a Part of it may be given freſh cut and green all the Summer, while the reſt is making for the Winter Service, or for Sale.

The beſt Seaſon for giving it firſt to Cattle green, is in the Spring, becauſe its natural Effect is purging firſt, and afterwards fattening them; but in this, as in Clover, there is ſome Danger of its making them ſwell at firſt, if given injudiciouſly: to prevent this Accident the Farmer will remember what we have ſaid of Clover, and uſe the ſame Precautions, giving them Straw among it firſt, or beginning by a little at a Time.

In this Way of giving it is ſafe for all Cattle, and agrees with all; nothing ſtrengthens or fattens a Horſe like it, and no Food whatſoever makes Cows yield ſo great a Quantity of rich Milk, or ſo little alters it in Flavour.

The great Danger of Cattle's hurting themſelves by it, will be avoided by their not being turned into the Fields, to eat at their own Pleaſure: this is always to be given them in Racks, and therefore the Owner may always proportion the Quantity at his Diſcretion.

In this Manner of uſing, a Field of Lucerne will continue in Heart many Years, nay there is no ſaying when it will be worn out.

The making it into Hay is the next Conſideration, and is of the greateſt Conſequence. The Profit is vaſtly great, and therefore it is worth the Farmer's while to be ſtrict in obſerving all the Particulars relating to it.

The principal are two, that it may be cut young, and that it may be well dried; as to the firſt it is prodigiouſly to his Advantage in every Reſpect, for the Hay will be ſweeter, and the next Crop will come much ſooner than if more Time were loſt, and the Roots exhauſted, as we have ſhewn they always are, when the Plants have ſtood to flower ſome time.

The Time to cut Saintfoin is when in full Flower; the Time to cut Clover is when beginning to get into Flower; but the exact and proper Time for cutting Lucerne is when it is preparing to flower, but has none fully open.

The Flowers of this Plant ſtand in Heads, in the ſame Manner as thoſe of Clover, but the Plant muſt be watched carefully for their Appearance. When they have formed themſelves is the Time of cutting the Crop; and in that Caſe, the Roots being full of Vigour, there will be a Shoot of four or five Inches high toward a new Crop, while the Hay is making.

There is no appointing the certain or exact Times of mowing the ſeveral Crops of this Plant, but it will be eaſily found by Obſervation; the firſt muſt be cut as ſoon as the Plants are in this Condition; and the others as they ſucceſſively get into the ſame State again after every mowing. This has all the Advantage poſſible. The Stalks of this Plant grow ſtubby and hard, when it ſtands too long; but they are by this Means cut while it is very tender; the Cattle are fondeſt of it when it is cut in this Condition; it leaves the Roots the ſtrongeſt, and the next Crop in Conſequence follows quickeſt; and being cut in the ſame Manner, when juſt getting toward Flowering, ſerves in the ſame Way the Farmer's Purpoſes beſt, and makes Preparation for the next in Succeſſion. Thus the Field of Lucerne, properly managed, yields from time to time, during the whole Summer, ſucceſſive Crops, and all very large ones, of an excellent Hay; and with Reſpect to the Horſehoeing, the oftener that is repeated the quicker the Crops will follow one another, and the more plentiful they will be.

While the Lucerne is in this proper Condition for cutting, the Stalks are ſingle, upright, and of a pale Green: after this, when the Flowers begin to open, they become branched and grow yellow, and then they ſoon will be ſticky, taſteleſs, and unprofitable. Therefore the Farmer's Intereſt is every Way concerned to ſeize upon the proper Time.

When it is cut the Mowers muſt have one general Caution, to keep their Scythes very ſharp, and to go on evenly and regularly throughout the Ground, for on the Smoothneſs of the Top depends, in a great Meaſure, the quick and numerous Springing of the Shoots for a ſucceeding Crop.

When mown it is to be ſpread upon thoſe Intervals left plain, or rolled ſmooth for that Purpoſe, and very carefully turned and dried. It requires a more careful Management in this Reſpect than either Clover or Saintfoin, for it is more apt to damage afterwards. It is in this Reſpect very apt to deceive the Farmer, for it will ſeem dry when it is not thoroughly ſo, and in this Caſe will be very apt to get damage afterwards, and ſo ſpoil the Hay of other Crops that happen to lie near it.

As to the Seed, that is uſually imported from France, but it is poſſible to bring it to Ripeneſs here; for this Purpoſe a warm dry Gravel, well expoſed, is to be choſe, as we have named before; and the Plants are to be thinned to a greater Diſtance. They will thus riſe into large and very numerous Stalks, and theſe muſt not be cut down at all, but left to follow the Courſe of Nature: their Flowers will thus appear in great Abundance, and after them the Pods, in which, if the Seaſon be favourable, the Seeds will ripen

to

to all the Perfection of ſuch as are brought from Abroad.

CHAP. XXIV.

Of Hop Trefoil.

WE have before ſpoken of the Uncertainty there is in the Huſbandmens expreſſing themſelves, concerning the Plants they cultivate. And this is another Inſtance: many of them call this Plant Trefoil, and others three leaved Graſs, and then ſpeak of its Culture or Uſes without any farther Diſtinction. This is the Caſe with the Writers on Huſbandry, as well as thoſe who practiſe it, and in them it is by much the moſt unpardonable. When they propoſe to inform the Ignorant in the Uſes and the Management of a Plant, from which a profitable Crop may be raiſed, 'tis very fit they ſhould firſt inform them what the Plant is: this they think they have done when they have called it Trefoil, or three leaved Graſs, not knowing, or not conſidering, that theſe are the Names of no particular Kind, but of all thoſe Plants which bear three Leaves on a Stalk. Trefoil is the Name of Clover, and of all the other Plants of this three leaved Kind, therefore there requires more Diſtinction. The Plant cultivated under the Name of Trefoil in certain Counties of ENGLAND, may be very well known under that Name, improper as it is, in thoſe Places; but the Inhabitants there do not want the Information: he who writes does it, or ſhould do it, for the Service of all Perſons: thoſe to whom he can be moſt uſeful upon that Head, are ſuch as live in Counties where the Plant he treats of is not cultivated, and who, by this Means, may bring it into Uſe there. Theſe can never get any Information what the Plant is by ſuch a Name, and it is needful to diſtinguiſh it by one more particular, and to eſtabliſh that Name by a Deſcription. This is the Courſe we have followed in the preſent Work, and ſhall continue in every Inſtance.

There are a great many Kinds of Trefoil, or Plants which have the Leaves always three on a Stalk, or three at a Joint, and theſe are all called by the Name Trefoil, but with the Addition of ſome Word, by which the Kind is diſtinguiſhed; one of theſe is the Trefoil, ſimply ſo called by the Farmers, and raiſed like the other artificial Graſſes for feeding their Cattle; the particular Diſtinction of this is, that the Flowers grow in ſmall Heads, reſembling a Hop in Shape, and from this it has been called Hop Trefoil, or Hop Clover, and in Latin Trifolium Lupulinum, which means the ſame. But as there are more Kinds than one of this Hop Trefoil, the largeſt is that choſen for Culture. Under this Name the Plant will be found treated of by all who have written on Herbs, and the Farmer knowing it by this Name, will always be able to inform himſelf and others about it.

This, though the largeſt of the Hop Trefoils, is but a ſmall Plant in Compariſon of moſt of the former, but it grows thick, and makes Amends for the Want of Height, by the Number and Quantity of its Stalks.

The Root is whitiſh, ſlender, and hung with Fibres; the Leaves ſtand three together, and are ſmall, oval, of a pale Green, and very numerous; the Stalks are eight or ten Inches high naturally, but they may be made taller by careful Management; the Flowers are ſmall and yellow, and they ſtand in oval Tufts or Buttons, which in a certain State much reſemble Hops: the Seeds follow, and are contained in dark coloured Huſks, and ſtand in a Head or Cluſter of the ſame Form.

This is the Hop Trefoil cultivated by the Farmer. It is a Native ENGLISH Plant, and therefore ſtands excellently all Weathers, and all Seaſons: for the ſame Reaſon it ſows its Seeds, and continues itſelf upon the Ground better than any of the foreign Kinds, and is up earlier in the Spring; this gives it a very conſiderable Value with the Farmer. The Plant that is ſure to be up early, that is too hardy to be hurt, and that gives a good, ſweet, and wholeſome Food to his Cattle, when he can ſcarce get it any where elſe, muſt needs be very valuable.

This was one of the firſt Improvements made by the ENGLISH Farmers, in the Way of the artificial Graſſes; but ſince the Introduction of the others it has been leſs regarded, though on many Accounts it is very valuable, and ought always to be in his Remembrance, as one of the many Crops by which he may vary his Courſe to the Eaſe of his Land, and his own great Advantage.

The Soil that ſuits the Hop Trefoil beſt, is a ſoft mellow Earth; next to this it proſpers in a light rich Loam: it will grow on almoſt any Ground, but beſt on theſe; and worſt of all on ſuch as are clayey or wetiſh. The Farmer who has a dry Piece of Ground, and has a Mind to a Crop of Hop Trefoil, need not ſcruple ſowing it let the other Condition of the Ground be what it will: he will have a better or a worſe Crop according as the Soil more or leſs ſuits the Plant, but he will never fail of having enough to anſwer his common Purpoſes. Hop Trefoil may be ſown alone or with Corn, in the ſame Manner as Clover, and in either Caſe will ſucceed very well; it has alſo a third Uſe, which is, the propagating it in common Paſtures. This is done by ſprinkling the Seed among the Graſs, where it freely comes up along with it, and greatly thickens it and improves its Quality.

When Hop Trefoil is ſown in the Field, whether alone or with Corn, it may be ſown either in the Huſk or naked; this is a Circumſtance to which the Farmer muſt attend with Care, otherwiſe he may be led into great Errors; the Quantity proportioned to an Acre differing very greatly, as the Seed is clean or with its Huſks. Different Soils may make ſome Variations needful, in Reſpect of this as of all other Seeds; this is a Subject we have conſidered before, and as it holds good in all Crops need not be repeated; but for a general Rule we ſhall tell the Huſbandman, that if he ſow the Seed naked and clean, he is to allow twelve Pound Weight of it to an Acre; and if in the Huſks he is to meaſure it, and allow to the ſame Quantity of Ground two Buſhels.

He will by this Diſtinction have ſome general

Gueſs

Gueſs alſo, at the Meaning of thoſe practical Writers, who are leſs nice in their Explanation than Practice requires; when he reads of Trefoil Seed by Weight, he will know it is meant of the clean Seed; when by Meaſure, of that in the Huſk.

Knowing the Soil and Quantity of Seed, the next Thing is the Manner of ſowing. As this is a Plant never expected to grow large, we ſhall not recommend the new Method of Huſbandry for it, but adviſe the Farmer to ſow it at Random, in the broad Caſt-way; and for many Reaſons ſhall prefer the Seed in its Huſks, rather than naked. This defends it from Injuries by Inſects, and from Damage by wet till it ſhoots, it makes it ſpread eaſier from the Hand, the Quantity being larger, and it ſhoots the quicker for it. This was the Intent of Nature, for the Seed falls to the Ground Huſk and all; and we ſhould be wiſer than we are, if we took Pains to follow her Inſtruction and Example in more Inſtances.

The Farmer thus ſowing two Buſhels of the Seed, Huſk and all, by the broad Caſt-way, will have a thick promiſcuous Crop early up; and it will, while it ſtands, be continually thickening itſelf more bythe ſhedding of its own Seed, which never fails to grow in Abundance; it will do this even when eaten upon the Ground, the Flowers being very numerous, and ripening in ſuch a Succeſſion, that there are always ſome Heads ready to ſhed their ripe Seed, let the Condition be what it will; but if it be let to ſtand for Hay there will be Millions of new Plants.

There are two Seaſons for ſowing this Trefoil, Autumn and Spring, in either of which it may be ſown according to the Farmer's Diſcretion, either alone or with his Winter or Summer Corn; but when the Choice is equal in other Reſpects, he may be ſure it will always ſucceed beſt ſown alone.

The Earth requires no great Preparation for this Crop, for the Plant being wild will grow any Way; the only Information that need be given the Farmer on this Head is, that the Seed will not grow if it be buried too deep. This will ſerve him to a double Purpoſe, firſt in inſtructing him to ſow it in ſuch a Manner, that it may be lightly covered; and afterwards to bury it by deep plowing, when he intends another Crop; for without this Care it will riſe among the Corn when not intended, and often be very prejudicial to it.

For ſowing Hop Trefoil the Farmer ſhould chuſe a calm Day, eſpecially as we have adviſed the ſowing the Seed in the Huſk; for in this Caſe, being large and light, the Wind would take Effect upon it, and ſcatter it very unequally, however ſteady and careful the Hand were that ſowed it.

When it is on the Ground the beſt Method is to draw a Roller over it, and then to harrow it very lightly. This is more Trouble than many take, but it is not much, and the Advantage in the Crop will very well anſwer it. The Rolling alone would be ſufficient, but that if a Shower comes it looſens the Seeds, and if a windy Day follows, it ſcatters it all at Random. In the Harrowing great Care muſt be taken to do it extreamly light, otherwiſe the Seed will be too deep buried.

The Crop thus ſown will riſe quick, and increaſe in Value every Year. It requires no Trouble; but may be fed or mowed at Pleaſure, and the beſt Management is to do both at the proper Times. It is hardier than any of the others, and leſs liable to any Kind of Damage: Cattle are very fond of it when cut and given them freſh in Racks, but they may be turned into the Field almoſt at any Time without Hurt. Of all the Plants of this Kind none is ſo wholeſome as the Hop Trefoil: ſome have found this ſo frequently by Experience, that they always ſow a Proportion of it among Clover, to prevent the Effect of that Plant, in ſwelling and diſordering the Cattle that eat it. They grow very well together; and the right Proportion is five Parts of Clover Seed, and one of clean Hop Trefoil.

The early Appearance of this Trefoil is of great Service to the Ewes and Lambs in Spring, and alſo to Cows and Oxen: it is therefore a Crop the Farmer ſhould never be without, in larger or ſmaller Quantity.

The greateſt Inconvenience attending it, is what we have named already, that he often finds a Difficulty to clear the Ground of it when intended for ſomething elſe; but we have given the Method of doing this effectually: it is only to bury it by a deep Plowing, for neither the Seed nor Root will grow when they are covered to any Depth.

CHAP. XXV.

Of Ray Graſs.

WE have ſeen the Farmer calling many of thoſe Plants which he ſows for anſwering the Purpoſes of Graſs, by that Name, though of very different Kinds; but this Ray Graſs is properly a Graſs only of a particular and valuable Kind. Its Uſe is the ſame with that of the ſeveral Kinds laſt mentioned, the ſowing for an early Food for Sheep and other Cattle, and none anſwers the Purpoſe better. It is hardier than any, and having the Appearance, and with it the Nature of the better Sort of the common Graſſes, it is the moſt eaſily propagated of any. It is hardier than the Hop Trefoil, and comes in even earlier than that to the Farmer's Service.

We have obſerved, ſpeaking of Paſtures, that there are a great many different Species or Kinds of natural Graſs, differing in greater or leſſer Particulars among one another. Ray Graſs is one of them, its proper Name is Darnel, in Latin Lolium. There are two Kinds of it, the white and the red, ſo called from the Colour of the Joints of the Stalks, which in the one are white, and in the other reddiſh: this is the Diſtinction as to Colour, but they differ in Size and Qualities. The white is the larger, and the red is the hardier of the two. They are both wild Kinds, but it is a great Advantage to the Farmer to ſow them, the red or ſmaller Darnel is the beſt Kind, becauſe it is earlier and hardier than the other,

other: and ſends up more numerous Leaves. The Farmers who do not underſtand Names much, and they have in this Article, for want of ſuch Knowledge, let in ſome Confuſion. We have obſerved the proper Name of this Graſs is Darnel. It is called Ray Graſs, and this ſome write Raye Graſs, and others, according to their Notions of ſpelling, Rey Graſs. This Rey has been ſpoken as if it were Rye, and thence others have written it Rye Graſs; now Rye Graſs is an English Name of another Graſs, one of the worſt and moſt unſerviceable of all the Kinds; it grows by Way Sides, and has a bearded Ear reſembling that of Barley: this, inſtead of being cultivated for Uſe, ſhould be rooted up as a Weed wherever it comes: yet this ſeems to be directed to be ſown and cultivated, by thoſe who write the Word Ray Graſs in that Manner.

The Graſs properly called Ray Graſs, and meant in this Place, is of a middle Stature among the Graſs Kinds, growing to a Foot and half high. The Root is a Tuft of thick and very many whitiſh Fibres: the Leaves are very numerous, and of a freſh Green, they are narrow and ſharp pointed, like thoſe of common Meadow Graſs, but ſhorter.

The Stalks are very numerous, and riſe among the Leaves; they are round, green, firm, and toward the Bottom very much jointed. The Top of each Stalk is covered with a Kind of Ear. This is long and thin, and is compoſed of ſeveral little Cluſters of Huſks, repreſenting ſo many little Ears going to make up the great one. In theſe are contained the Seeds, which are not unlike the Grains of ſome of the Corn Kind in Shape, but ſmaller.

This is the Deſcription of Ray Graſs in its natural wild Way of growing, and in which it is common about Foot Paths and in Paſtures, naturally growing in a ſcattered Way in many Places. It does not ſhew much Difference by Means of Culture. The Leaves are more numerous when it has a good Soil, and the Stalks, if permitted to riſe to their Height, will be much taller; but this is not the Farmer's Intereſt, for as they grow large they grow hard, and are leſs uſeful.

Ray Graſs may be ſown either alone or mixed with Clover, or other of the artificial Graſſes, as we have ſhewn in treating of them; and this is the beſt Way of managing it.

Any Soil will ſuit Ray Graſs, and this is a great Advantage. We have been obliged to caution the Farmer, againſt ſowing ſeveral of the laſt-mentioned Plants upon clayey or wet Soils, becauſe they will not ſucceed thereon; but this is a Graſs for Land that will ſupport no other. Ray Graſs will grow to Advantage on cold, wet, ſpewy, and ſower Land, and is therefore a very great Improvement.

There are Crops intended for the Food of Cattle, which are deſtroyed by a very dry Summer, or at beſt rendered of little Uſe or Value; but this is not the Caſe with Ray Graſs, no Drought of Summer, and no Froſt or Wet of Winter hurts it: the Farmer therefore ſhould always have ſome Land ſown with it, becauſe it will ſtand him in ſtead when all the reſt fail. It is one of the beſt Winter Foods for large Cattle, and one of the earlieſt Spring Foods for the ſmaller, and at the ſame time there is none more wholeſome: it not only is excellent itſelf, but, as we have before ſhewn, it ſerves to correct the bad Qualities of the others.

Ray Graſs feeds Horſes in a very hearty Manner, and is of ſo dry a Nature that it will prevent the Rot of Sheep.

No Field will bear ſo large a Stock as one of Ray Graſs, becauſe nothing can hurt it; nor is there any Harm, but rather Advantage in eating it very cloſe, becauſe the worſt Damage that can attend it, is the growing too high. The Stalks are as tender and full of Nouriſhment as the Leaves when young, and they grow up immediately after biting.

When the Farmer ſows Ray Graſs with his Clover, for the Sake of correcting the bad Quality of that Graſs, a ſmall Proportion of Ray Graſs, ſuch as we have named on that Head is ſufficient; but when he intends to have the full Advantage of the Crop in feeding his early Cattle, he ſhould much enlarge the Quantity. Three Buſhels of Ray Graſs Seed is a very proper Quantity for an Acre, in a Mixture with Clover, or more may be allowed. In general, after theſe Hints, the Huſbandman will be able to proportion the Quantity to the intended Service; and as the common Cuſtom is to ſow a great deal of Clover, with a little Ray Graſs among it, he will often find it prudent, where he is to depend upon a Paſture for a conſiderable Time, to ſow it with a great deal of Ray Seed, and a little Clover.

It is the Effect of Ray Graſs to make the Clover laſt a great many Years longer than it naturally would, in whatever Proportion it be mixed with it; but if the Farmer chuſe to allow it a large Share, the Paſture will be good as long as he pleaſes. The Ray Graſs, Hop Treſoil, and Clover, will grow excellently together, where the Soil is tolerably dry; and in that Caſe there is no Way of making a richer Paſture, than by ſowing a large Proportion of the Ray Graſs, with an equal Mixture of the other two, in about an eighth Part Proportion of each to the Ray Seed.

Beſide the excellent Quality of Ray Graſs, in growing on clayey and other bad Soils, it will in a very powerful Manner, deſtroy the worſt Weeds that grow naturally in the others. It is obſerved that where Ray Graſs is the principal Growth, there are few Thiſtles, and if thoſe are but once tolerably got up, they never riſe again; the Reaſon is plain, and the Fact of great Importance. The Ray Graſs covers the Ground with ſo thick a Turf, and draws ſo large a Quantity of Nouriſhment, for the Supply after its conſtant Cropping, that no Seeds can get in, and if they do the young Plants that riſe from them are ſoon ſtarved. The keeping one of theſe Grounds free from this Annoyance, is a very conſiderable Article.

The mowing Ray Graſs is an Article that requires a great deal of Circumſpection and Conſideration, it makes a very good Kind of Hay, and its Seed falling from it, in that Condition, is of ſome Value; but here the two Points of

Profit interfere with one another, for if the Graſs be cut young the Seed will not have its full Size or Hardneſs; and if it be let to ſtand for that Purpoſe the Hay will be harſh, from the Dryneſs, Coarſeneſs, and Hardneſs of the Stalk.

In this the Farmer who would act moſt judiciouſly, ſhould take a middle Courſe, cutting down the Ray Graſs, not while the Seeds are too young to be uſeful, nor letting it ſtand till they are ripe, and the Stalk hard, but coming in when the Seeds are beginning to ripen, and the Stalk is yet tender, thus he will make good Hay, and have tolerable Seed, ſome of which, if not all, will be ſure to grow.

If he particularly want the Seed for ſowing ſome other Piece of Ground, he muſt let the Crops ſtand ſomewhat longer before mowing, and for the Sake of good Seed be content to ſpoil his Hay, in ſome Degree; on the other hand, if he have no Regard to the Seed at all, he ſhould cut the Ray Graſs juſt when the Ears are beginning to form themſelves upon the Stalk, he will thus have an excellent Hay, and the Roots being unexhauſted by Ears, will ſend up a freſh Shoot in a ſurpriſingly ſpeedy Manner, for feeding on the Ground, or for a ſecond Crop.

The Seed is not an Article of very little Conſideration, for it brings ſome Price; and when the Crop is ſuffered to ſtand for it, four Quarters will ſometimes be got from an Acre; this at about Two and Nine-pence a Buſhel, which may be called a moderate Price, is worth ſome Loſs upon the Article of Hay. Some who think of the Hay as the principal Crop only, gather ſuch Seeds as are found at the Bottom where it is put up; but in this Caſe, where a Profit is depended upon from the Seed, it ſhould be thraſhed for it in the ſame Manner as Corn: and the Hay, far from getting any Injury by this Management, will be the better.

At any Time if the Crop of Ray Graſs be thin, it may be thickened by ſowing ſome more of the Seed; if this be ſcattered at Random among the Graſs, it will take, and encreaſe the Quantity according to the Proportion uſed, which may be a Buſhel or two for each Acre. The beſt Seaſon for doing this is Spring, but it may be done in October.

This Graſs has many a Time ſaved the Farmer's Stock of Sheep and Lambs, very early in the Spring, from ſtarving; and at all Times it is an excellent Preparatory for the richer artificial Graſſes which riſe, in Point of Time, after it.

Some have ſuppoſed what is called Long Graſs in ſome Parts of Wiltshire, to be the ſame with Ray Graſs, but it is a great Error, that is a Kind of Water Graſs, with very long Stalks, which will grow but in few Places: it is very uſeful where it will take, but it requires a rich Soil, and a proper Degree of Moiſture, ſo that it is in vain to think of making it univerſal. This Kind ripens its Seed but poorly, which is the Condition of many other Plants that creep abundantly at the Root, Nature having given that as the Means of their Propagation, and therefore leſs regarding the other. When the Farmer ſhall happen to have a rich wettiſh Piece of Meadow Ground, he may at any Time try this Species in it. 'Tis always to be found about ſhallow Waters, and may be known by the Length of its Shoots, which trail along the Sides, or float upon the Surface. Theſe being ſtuck into a damp Ground, already covered with other Graſs, may take their Chance: if they meet with a Soil, and all Accidents proper for them, they will thrive and be very uſeful, if not there is no Harm done by the Tryal. It is worth making in this Way, becauſe attended with little Expence or Trouble; if it do not ſucceed 'tis vain for the Huſbandman to attempt raiſing it by Seed, for of that little comes to ſuch a Ripeneſs on the beſt nouriſhed Plants as to grow; and if it were ever ſo vigorous, without the Particularity of juſt a right Soil, it will come to nothing.

The Place where this Graſs was firſt obſerved by the Farmers, was a Piece of Meadow Ground near Maddington, a few Miles from Salisbury; and the Effect of it being ſeen in that Place, they endeavoured, but without Succeſs, to propagate it in ſome others. The Stalks in this Meadow grow to the Length of eight or nine Yards, rooting at every Joint, of which there would be twenty or more in ſuch a Length, and it proved an excellent Food for Sheep. The ſame Graſs has been obſerved in other Places, and always remarked for its great Length: Sheep in particular are fond of it; and they will eat it greedily as it grows about Waters, as well as when it mixes among the other Graſs of Meadows.

With Reſpect to the other Species of common Graſs, numerous as they are, none thinks of cultivating one more than another. In general, thoſe which moſt reſemble the common Meadow Graſs are beſt, and ſuch as are ruſhy, or have triangular Leaves with ſharp Edges, are the worſt; theſe are principally Natives of ſower Land, and watery Places. As to the Ray Graſs, when it grows natural among other Paſture Graſſes, it is always an Advantage, and we have ſhewn how it is to be raiſed to great Service by proper Culture.

****

CHAP. XXVI.

Of Spurrey.

THIS is a Plant very little known among our Huſbandmen of the preſent Time, and not to be ranked with many of the preceding in its Utility; however, as it was once ſown in our Fields, and is at this Time propagated in Flanders, and ſome of the Neighbouring Kingdoms; and as it is not without its Uſe, we have thought it not unworthy a ſhort Chapter, at the End of this our ſeventh Book, treating of thoſe Plants of Graſs or other Kind, which are raiſed for the Service of the Farm as Food, at Times when other Species are wanting.

Spurrey is a wild Plant in this Country, and therefore will not fail to ſucceed eaſily with any Kind of Culture; as it naturally grows

in

in our Corn Fields, it ſhews that Tillage will always be uſeful to it; and as it will grow in very poor Ground, and come into Service late in the Year, when many other Crops are eaten, it is worth ſome Notice.

It is a ſmall weak Plant, with little five-leaved Flowers, and a great Number of Seeds following each in a Kind of Capſule. There are five Kinds of it Natives of ENGLAND. 1. The larger or common Spurrey, frequent wild in Corn Fields. 2. The little annual Spurrey, with foliated Seeds. 3. The common little red flowered Spurrey, wild in dry Places. 4. The Sea Spurrey, frequent on our Sea Marſhes. And 5. The leſſer blue flowered Sea Spurrey.

Of theſe common Spurrey, and the Sea Spurrey, the firſt and the fourth Kinds named here, are the only ones worth the Farmer's Notice; and of theſe the firſt is the only one at preſent regarded.

This is a weak Plant, with numerous Branches. The Root is white and ſmall, but full of Fibres. The Stalks are eight or ten Inches long, and divided into many Branches not very erect, tender, and of a pale Green. The Leaves are very narrow, and there ſtand ſeveral of them at every Joint: at the Tops of the Branches ſtand the Flowers, which are ſmall but very conſpicuous, being of a bright milky White.

The Soil that moſt ſuits the Growth of this Plant, is a mellow Earth, with a large Admixture of Sand; and it will thrive very well in Expoſures, and the moſt barren Places.

The Ground requires no great Care for fitting it to this Crop. There are two Seaſons for ſowing it, the firſt is in MAY, and the other very early in Autumn: in both Caſes it ſhoots very quick, and preſently covers the Ground with a green Coat, though in a ſtraging Manner.

The Uſe of it is as Fodder for the Cattle, principally Cows; and the Way of giving it, in FLANDERS where it is moſt cultivated, is freſh cut in Racks. The Produce of the latter ſowing comes at a very advantageous Seaſon, the natural Graſs in their Paſtures having been well eaten by that Time, and recovering itſelf but ſlowly.

It is an excellently wholeſome Food, and one that Cattle are very fond of: it occaſions Cows to give a large Quantity of Milk, and gives it no ill Flavour, as too many of theſe Things will: it alſo fattens Cattle of all Kinds, and, as is ſaid, occaſions Hens to lay more Eggs than any other Food. 'Tis plain thoſe Fowls are fond of it, and at the worſt it never has been found to do them any Harm.

If the Huſbandman ſhall chuſe to cultivate this Plant, the Method he ſees is very eaſy, ten Pounds of the Seed, which may be had very cheap from HOLLAND, is the proper Quantity for an Acre: it requires only to be lightly harrowed in, after ſowing in the common broad Caſt-way, and then will give no farther Trouble till the Time of cutting, which will be in about three Months after the ſowing.

We have mentioned among the five Species of Spurrey, one beſide this common Kind, which may be well worth the Farmer's Notice; this is that Sort which grows about our Sea Coaſts. It has not yet been conſidered as an Herb at all profitable, but this is becauſe it is not known among thoſe who ſhould bring it into Uſe. The Knowledge of Plants is confined to People of Curioſity, it will be very happy if it ever ſhall be made univerſal.

This Sea Spurrey, with which we are deſirous to bring the Farmer acquainted, is much more worthy his Notice than the other. That we have not greatly recommended, becauſe there are many other Crops, probably moſt of them ſuperior in Value to it, which will grow on the ſame Ground, and with not more Trouble in the Culture, but it is not ſo with Reſpect of this.

There is nothing we want more than to find proper Growths for our Sea Coaſt Land, and this is one that Nature has calculated for that Purpoſe. We have a vaſt deal of Ground within the Reach of Salt Water, which is therefore neglected; becauſe being impregnated with Saltneſs, things uſeful will not grow upon it: there would be a vaſt Advantage in finding Crops proper for theſe Grounds; and if they were but of a moderately valuable Kind in themſelves, ſtill, becauſe they grow on what would be otherwiſe unprofitable Land; they would be uſeful. We ſee the great Benefit of draining thoſe feeding Grounds which become Salt Marſhes, and there will be the ſame or more in raiſing Crops of uſeful Herbs, of whatever Kind, on ſuch as are not fit for that other Purpoſe.

We find many Pieces of Ground in this Condition, the Soil whereof is too looſe and ſandy to bear a good Turf. On theſe, which cannot be made to anſwer in the common Way of Salt-marſh Ground, the Sea Spurrey might be raiſed with Profit. There can be no doubt of this, becauſe the Plant grows wild upon them; and I am able to acquaint the Farmer, from Experience, that this Kind of Spurrey is equal to the other ſo commonly ſown in FLANDERS, and at one Time not uncommon in ENGLAND, in its Qualities: let it not ſeem the Fondneſs for a Piece of Novelty, that influences me, when I ſay it is better; for it is as wholeſome and more juicy; and conſequently every Plant of it contains more Nouriſhment than one of the other.

This Sea Spurrey, which we propoſe to the Huſbandman who ſhall be ſituated near ſuch Land, to cultivate, is not unlike the former in its Manner of Growth, or the Shape of its Leaves or Flowers; but it is ſhorter, more upright, and has a fuller Stalk. The Farmer will ſee it frequent on theſe Sort of Grounds, and will know it without farther Deſcription.

It is ſo plentiful that the Seed, though it is not to be bought, may eaſily be gathered in Abundance; a Couple of Labourers in the Month of JULY, being employed one Day for that Purpoſe, would be able to bring in a vaſt deal of the wild Plant; it is at that Seaſon very full of the Seeds, and they will freely come out on threſhing; theſe may be ſown

with the leaſt Expence imaginable, and they will that Year produce a large Crop, and that at a Time when it will be very uſeful.

When the Seeds are got out of the dried Plant, they muſt be ſpread upon a Floor to harden; and after a Week they will be fit to ſow. That ſhort Compaſs of Time will be enough for plowing up a Piece of waſte Ground, which will need no farther Culture than this. Let it be well turned up by a Plow that will cut deep, and then harrowed over. After this let the Seed be ſown by the broad Caſt-way, in the Quantity before-mentioned, and then let a Roller be drawn over the Ground, to preſs it in.

The Land in ſuch a Place is of little Price, all this Trouble and Charge will amount to, in a Manner, nothing, and there will undoubtedly be a Crop. Its Uſes being the ſame with thoſe of the common Spurrey, the Farmer has been told them already; and if it do but equal that there will be Advantage in the Attempt; but he may be aſſured it will very conſiderably exceed it. This is one of thoſe Trials we have to propoſe to the induſtrious and ſpirited Farmer, and like all the reſt, it may be attended with conſiderable Good, but can do him very little Harm.

End of the Seventh Book.

A COMPLEAT BODY OF HUSBANDRY.

BOOK VIII.

Of such Roots as may be advantageously planted in Fields.

In ELEVEN CHAPTERS.

CHAP.

1. *Of the Soil for Turneps, and Manner of sowing them in the common Husbandry.*
2. *Of managing Turneps in the Ground.*
3. *Of the Uses of Turneps.*
4. *Of certain particular Ways of raising a Crop of Turneps.*
5. *Of the Potatoe.*

CHAP.

6. *Of the Soil for Potatoes, and the Manner of planting them.*
7. *Of the preserving of Potatoes.*
8. *Of Carrots.*
9. *Of the Soil for Carrots, and its Preparation.*
10. *Of sowing of Carrots.*
11. *Of managing a Crop of Carrots, and their Use.*

The INTRODUCTION.

WE have had Occasion to observe in several Places, in the preceding Part of our Work, that the Gardener and Farmer are intrenching upon one another's Province; the Gardener planting his proper Crops in the Field, and the Husbandman employing himself about the Products generally supposed to belong to the Garden. This is no where so much the Case with the latter, as in the present Instance.

We are in this Book to treat of Roots which the Farmer may advantageously cultivate in Fields, but which have been originally, and are in general still at this Time, the Products of the Garden. These he will find it easier to manage than many of his more usual Crops; and we would in this Work let him into the Knowledge of every thing that can be profitable to him. A Field is a great Garden, if he pleases to make it so; and the main Difference lies in the Degree of Culture. For many of the common Products of the Garden the well managed Labours of the Field will answer; and if he add to these more Expence, and a different Manner of working, he will find it perfectly answered by the Encrease and Value of the Production.

There are many Roots that may be cultivated in Fields, and that are so at present in one Part or other of the World: with all these we shall bring him acquainted, and with their Manner of Culture; but there are three principal Species at this Time propagated, in the Fields of many Parts of our own Country with great Benefit, and which we wish could be thrown into the Farmer's Hand universally: these are the Turnep, Potatoe, and Carrot. The Demand for these is continual and great, so that there is no Danger of over-stocking the Market; and as they bring the Farmer in some Places a very great Profit, we shall endeavour to enlarge that Branch of the Profession.

After these are to be named the other Roots, we have mentioned some of them propagated at present only abroad, and others confined to one or two Spots of the Kingdom; these we shall separate from the present, treating of them

in a ſucceeding Book, together with thoſe other Products, whether Leaves or Flowers, which are in the ſame Manner in every Huſbandman's Power to cultivate to Advantage, though they are not yet well introduced among us.

Of the three Roots we have to treat of in our preſent Eighth Book, the Reader is to remember, that we have ſpoken of the firſt already, ſo far as the Drill and Horſehoeing Huſbandry are concerned in its Culture; to avoid Repetition therefore, we refer to that Head for many Particulars relating to the Turneps as raiſed by that Method for the Service of the Stock, and ſhall here treat of it only as propagated in the Field by the common Huſbandry, by which it may always be raiſed to equal, and commonly to excel in Sweetneſs, that of the Garden.

CHAP. I.

Of the Soil for Turneps in the common Huſbandry, and Manner of ſowing them.

A Poorer Soil will do for Turneps in the Horſehoeing Huſbandry, but in the common Way of Management we ſhall adviſe the Farmer to look upon them as a Garden Root, and to give them what is as near a Garden Soil as his Field will afford. In that Practice freſh Supplies of Nouriſhment may be given them, by dreſſing the Ground by Tillage while they are on it; but in the common Way nothing eſſential can be done to that Purpoſe, the Turneps are to truſt to ſuch Nouriſhment as is in the Ground when their Seed is committed to it; therefore the richer it is the better.

A good black mellow Earth, with ſome ſmall Admixture of Sand, or a very rich Loam with a great Quantity of mellow Earth among it, are the moſt favourable Soils for the Turnep in the Field. We would have our Farmer raiſe his Turneps to equal thoſe of the Garden, and there is no other Way but by a firſt good Choice of the Soil. Whatever be the Condition of Land on which they are ſowed in other Reſpects, two Qualities it muſt have, that it be light and warm, theſe will prevent the Deſtruction of the Crop; but we muſt add the other Quality of Richneſs, in order to their being well nouriſhed.

Turneps ſtand a great deal cloſer this Way, than in the Drill and Horſehoing Method, and therefore there muſt be more Richneſs in the Land that is to ſupply them. A Soil too ſandy is never very rich, this is the material Objection to that Kind of Land, which otherwiſe, from its Lightneſs and its Warmth, would be proper; as to Clays, they being heavy and cold, are, of all Soils the worſt for Turneps: the other Kind, as they approach more or leſs to the one or to the other of theſe, are the fitter or more unfit for the Growth.

The Quantity of Seed for the ſeveral different Methods of Huſbandry we have mentioned before, and ſhall add here, that there is a Nicety in covering the Seed which few regard, and Errors in which are the Cauſe of half the Miſcarriages that happen to Turnep Crops. This Seed requires to be tolerably well covered, and in particular to have the Earth preſſed cloſe about it. From the Want of this ſingle Circumſtance, I have ſeen Crops that had every other favourable Accident that could be named to attend their Growth, come up poorly, and half of them decay afterwards, while the Remainder came to little or nothing.

On the contrary, there is no Danger of ſqueezing and preſſing the Earth too firmly about them; for we have ſeen very fine Crops of this Root raiſed, by ſowing Turnep Seed in a Barley Field juſt before mowing. In this Caſe it is eaſy to conceive how the Ground muſt be every where ſqueezed, by the treading and carrying off the Corn; but this, far from hurting the Seed, has ſent it properly into the Ground, and the Stalks of the Barley ſheltering it, have done inſtead of a better Covering.

As we ſee by this what Degree of preſſing Turnep Seed will bear, when in the Ground, we ſhould give it accordingly, but in a more regular Manner. The common Harrow tears up the Ground too much, and buries the Seed too deep; the beſt Way therefore is, when it is ſcattered properly upon the Field, to draw a Buſh Harrow over the Ground, by Way of covering it lightly, and then to go over it with a very heavy Roller. There is alſo another Method that may be uſed for ſowing of Turnips, which is, to have a wooden Roller ſtuck full of ſhort Pegs, then drawing it over the Ground the Seed is to be ſcattered in, and a Buſh Harrow is to be drawn over it afterwards, which will ſufficiently level the Ground.

This Article of preſſing down the Earth about the Seeds, though very eſſential to the good Growth of this Plant, is not particular to it, but is of excellent Uſe in many others; we ſee ſomething like it practiſed on many Seeds in Gardening, which they tread in firſt, and then lightly rake the Earth over afterwards. A good Roller would anſwer the Purpoſe of this treading, when the Seed had been in the ſame Manner ſcattered over the Grounds, and it would be eaſy to have the Harrows with ſhort ſharp Tines, that ſhould anſwer the Purpoſe of their Rakes. This would be a Means of bringing the Garden Method of working, in many Inſtances, into the Field, and in none it can be more proper, than when Things which are common Garden Products are concerned.

The great Danger of the Fly may be, in ſome Meaſure, obviated by a proper Steeping of the Seed before ſowing. There is an excellent Receipt among the Farmers for this Purpoſe, the Succeſs of which has evidently been ſo great, that it were idle to think of propoſing any Alteration in the Ingredients. What we have ſeen in the Difference of Crops that have been ſown with this Advantage, and others in the ſame Circumſtances, the Seeds of which were ſown without ſteeping, makes us very deſirous that it ſhould be univerſally known, and univerſally followed. The Receipt is this. Mix together equal Quantities of Stone, Lime, and Wood Soot. Have ready a Quantity of Urine, ſufficient to moiſten them into a thin Pap. Heat a little of the Urine and put to the reſt, that it may be all Milk-warm, then mix it by Degrees with the Lime

Lime and Soot. The Lime will preſently ſlake, and breaking to Pieces, the whole will make a ſmooth Maſs of a thin Conſiſtence, pour this when cold upon the Turnip Seed, let it remain in it four and twenty Hours, and then ſow it in the Manner we have directed.

CHAP. II.

Of managing Turneps in the Ground.

THE firſt Care is to watch the growing Shoots while very young, to ſee whether they be taken by the Fly. It is impoſſible to guard perfectly againſt this Accident, but it is very proper to be upon the Watch, to know it as ſoon as poſſible, for it ſhould be repaired by an immediate other Crop.

We have obſerved before, that this Danger is only while the Turnep is in its Seed Leaf, becauſe theſe Inſects do not regard it afterwards. The Taſte of theſe Ingredients will, in ſome Degree, hang about the Seed Leaves, ſo that they will be more likely to eſcape when it has been ſteeped, than when ſown without that Precaution; but I have ſeen it ſometimes eaten down by them after this Method; and therefore warn the Farmer not to truſt to it entirely, though it give him great and reaſonable Hopes.

When the Crop has got over this Danger, the next is its being ſtarved by Weeds. Several Kinds of theſe will grow among Turnips as among other Crops; but there is one particularly miſchievous, this is Charlock, it reſembles the Turnep ſo much in the Leaf, and Manner of growing, that it may riſe among it in great Quantities unnoticed; nor is it always ſafe to order it to be weeded out, for there have been Inſtances of the Weeders taking up a whole Crop of Turneps, and leaving all the Charlock, this being a Time when the Turnep has not got any thing of a Root, whereby it ſhould be diſtinguiſhed. The proper Weeders at this Seaſon are Sheep, they will diſtinguiſh where the Labourer cannot, and what is very ſingular and very happy for the Farmer, they will, in this Period of the Growth, prefer the Weed to the Crop.

He is therefore firſt to inform himſelf thoroughly of the Difference between Charlock and Turneps, which conſiſts in the Size, Colour, and Diviſions of the Leaf; and though there be a general Reſemblance to an unpractiſed Eye, this is a very ſufficient Diſtinction to thoſe who will look narrowly. If he find his Turnep Field over-run with this deſtructive Weed, let him turn in a competent Number of Sheep; and they will eat off all the Charlock, which will never riſe to any Height again, and they will leave the Turneps untouched. This might ſeem a very deſperate Undertaking to ſuch as had not ſeen it practiſed, but there is no arguing againſt Experience, and this is a Method that has ſtood the Teſt of Ages. The only Caution is, that too many Sheep be not turned in: a very moderate Number will be ſufficient for the Purpoſe, and more might damage the Crop which they did not devour.

The Charlock being removed, the Diſtance of the Plants is to be conſidered; and as they generally riſe a great deal too thick from this random Way of ſowing, they are to be reduced in Numbers, and brought to this proper Diſtance by the Hand Hoe. This at the ſame Time clears off the Weeds, of whatever Kind, that have riſen among the Turneps; and they are left by it at a proper Diſtance, and with a clear Ground freſh broken for their Nouriſhment. The due Diſtance for the Crop we have ſhewn already, and ſhall not repeat any thing before delivered here. This hoeing is all the Farmer can, in the common Method of Huſbandry, do for his Crop; therefore when this is done he is to wait their Growth, as Nature brings them to their Perfection. As they arrive at that there is a Method of uſing them which will be of great Service, and which is ſo plain and obvious to Reaſon, that it ſeems aſtoniſhing it is not univerſally practiſed.

The firſt Uſe of the Turneps is to feed Cattle under Cover, and for this Purpoſe a proper Quantity are daily to be pulled up, and carried Home in Carts. I have frequently ſeen the Farmer's People at work upon this Plan, beginning at one Corner of the Field, and clearing all off carefully as they went on, that by Degrees a good Part of the Field has been left bare, while the Crop was growing on the other. Nothing can be more contrary to good Senſe than this Practice. The Farmer has here an Opportunity of bringing his Field into better Condition every Day, and for want of a little Thought it is utterly neglected.

None can diſpute but that the Turneps raiſed by the Drill and Horſehoeing Huſbandry, are vaſtly larger than thoſe in the common Method: this is in a great Meaſure owing to their Diſtance. The greateſt Advocates for that Practice urge, as a Reaſon, that the Turneps in the common Way of Culture, are ſtarved by ſtanding too cloſe; and here is an Opportunity of thinning them. When ſome of them are to be pulled for feeding in the Houſe, the Trouble will be little more to gather them in different Parts of the Field; and the Benefit will be very great.

Let the Perſons ſent to pull the Turneps, have Orders to draw them in ſuch Manner as to thin the reſt of the Crop regularly. The very pulling of them up will break the Ground a little, and every thing of this Kind is an Advantage: the Turneps left in the Field will be thus at greater Diſtances, wherefore they will grow to a larger Size; ſo that it is very natural to expect, and it will be anſwered in Fact, that they will make Amends by their Encreaſe in Bulk, for all that are taken up; and the Crop ſhall be in reality not diminiſhed in Quantity, but only in Number.

CHAP. III.

Of the Uſes of the Turnep.

THE Uſe of the Turnep at our Tables is ſufficiently known, and it were idle to enlarge upon it here. All that the Farmer is concerned to know about it is, that it will always make

make a Demand for them, and that this Demand will be proportioned to his Situation, near or remote from a Market; and according to the Bigneſs of that Market when he is near one. Of this he is certain that he may, on theſe Occaſions, ſend a Servant with a larger or ſmaller Parcel of his beſt Turneps to Market, according to the Demand, and they will make a very pretty Addition to his Profits.

If he live in the Neighbourhood of a great Town, it will be worth his while to keep his Crop wholly for that Purpoſe, or to make only ſuch a Reſerve of the worſt Part, as may be juſt needful for his Cattle; and he will thus be a Gardener, only in a larger Way: for his Field, managed as we have directed, will ſupply him with Turneps in every Reſpect equal to thoſe from the beſt Gardens. Not to purſue this Conſideration farther, we are now to enquire into the beſt Manner of giving Turneps to Cattle, and the various Kinds that will eat them; the Seaſons at which they are moſt proper, and their ſeveral Services.

It was thought at one Time a great Piece of Huſbandry, to chop Turneps to Pieces before they were given to Cattle; but this has been found to have had, inſtead of good, bad Conſequences, and is now utterly omitted. This tempted the Creatures to eat them without chewing, by which Means they had not half their Nouriſhment, and ſome times they were choaked with the Hurry of ſwallowing them: chewing is a natural Part of the Operations promoting Digeſtion. We have many People liable to great Diſorders in their Stomach, only from a careleſs and haſty Manner of eating; and the ſame Diſorders will ariſe to Cattle from the ſame Cauſes, eſpecially to thoſe which eat a Food ſo uncommon in their natural State as Turnips. The proper Method, on all Occaſions, is to give them whole, and it is in general much more profitable to pull them in proper Quantities, than to turn the Cattle into the Field. They eat up more entirely what are given them, ſo that there is no Waſte from their leaving, or from their trampling; and they fatten much ſooner when thus kept up, than when they ramble about.

The only Inconvenience attending fattening of Cattle with Turneps is, that it will give a Flavour to their Fleſh: but this is eaſily remedied, by feeding them at leaſt ten Days or a Fortnight with Hay; in which Time the Effect of the former Food, as to Flavour, will be entirely gone off.

Some Creatures have been ſuppoſed to be incapable of fattening with Turnips, becauſe they do not readily take to them; but theſe muſt be humoured into it. We have obſerved already, that the Turnip is not one of the common or moſt natural Foods of many of thoſe Animals, to whom it is very wholeſome. When any Creature the Farmer has a Mind to feed with the Turnip, does not take kindly to it at firſt, the Way is to boil it. And thus it will often go down, after which, the Taſte being known, it will be very well reliſhed raw.

If the Farmer be in Fear of the Fly for his Crop of Turnips, he may uſe ſome Precaution beſide what we have directed, in the ſteeping of the Seed: Wood Aſhes are found very deſtructive of this little Inſect; it is therefore a good Method to ſcatter a Parcel of theſe thinly over the Crop, juſt after the Plants are above Ground: it will often preſerve them; and is ſo far from doing Harm that it will always promote the Growth.

After this Fly, the greateſt Enemy to the Crop of Turnips, is the Caterpillar. It is a particular Kind that ſeizes upon the Turnep Leaf, and this only devours it while young. It is a ſmall black Kind, that will be found very plainly when it is in ſufficient Number to do Miſchief, for it can do this no otherwiſe than by the Multitude, like the Fly. When theſe are ſeen the Weather is to be conſulted, for in a dry Seaſon they may be deſtroyed at once by proper rolling, but in wet Weather that Inſtrument muſt not be brought upon the Ground. Therefore, if the Condition of the Land, and of the Air, permit, let a Roller be drawn carefully over the whole Ground, very early in a Morning. The Caterpillars will at that Time be out on their Food, and their Bodies being tender, the Roller preſſing heavily, and the dry Earth making ſome Reſiſtance, they will be utterly deſtroyed. This Preſſure of the Roller, far from injuring the Turneps, will make them root the better.

The naked Snail, or as it is commonly called, the Slug, is alſo very troubleſome on theſe Occaſions. If it be at a proper Time of the Growth, the Roller uſed in the ſame Manner, will deſtroy that alſo; but if the Turneps are at ſuch a Growth that the Roller cannot be taken on, then the Method is to turn in ſome Ducks, they are fond of theſe Creatures; they will do no Harm to the Turneps; and their Dung will help the Ground.

Theſe are the general Methods of raiſing the Turnep, and of preſerving it in its Growth.

But beſide theſe are ſome other Methods, approved by Experience, and worth the Farmer's Notice.

CHAP. IV.

Of particular Ways of raiſing a Crop of Turneps.

FIRST, there may be a very good Crop of Turneps got by ſowing them upon the Stubble, as ſoon as the Corn is off. The Seed, in this Caſe, is only to be harrowed in, and the Crop reſerved till late in the Spring, for the Food of Ewes and Lambs. If the Land be intended for Fallow, in the open Field Countries, they may very well ſtand on it till April, which will make a Supply for Sheep at that Time of the Year, when Proviſions are moſt ſcarce of all. A great deal of the Succeſs of this Crop depends upon the Seaſon, for if the Winter be very ſevere it often comes to nothing; if mild it ſeldom fails, and in the other Caſe the Loſs is trifling.

Another Method which has been practiſed with great Succeſs, is to ſow the Turnep Seed pretty thick among a Crop of Hog Peaſe, juſt when they are ready to cut. No more Care need be taken in this Caſe, beſide the ſcattering the

Seed in proper Quantity over the Ground, among the Pea Stalks, but this Quantity muſt be as we have ſaid, larger than is commonly allowed, becauſe ſome will certainly be loſt. The Reapers are then to be ſent in with their Hooks, and no particular Orders need be given them concerning the new Crop. Let them cut and carry off the Peaſe in the uſual Way, and the natural and neceſſary treading of the People's Feet will cruſh the Seed of the Turneps into the Ground, and preſs it down a little, which is every Way aſſiſtant to the Growth of this Species.

In this Manner, when the Peaſe are off, and the Ground has been a little at Reſt, the Turneps will ſhoot up, and they will be in leſs Danger of Inſects at this Decline of the Year, than they would have been in the wet and warm Part of Spring; if they appear the ſame Methods may be uſed to deſtroy them, and, one Way or other, the Farmer has a fair Chance for a good Winter Crop.

When they are at ſome little Height they will require to be hoed by Hand, for two Reaſons, the one is to thin them, the other to break the Ground about them. The Weeds are deſtroyed in Conſequence, but this is a leſſer Conſideration, for at this Seaſon they are fewer than in Spring.

The Neceſſity of thinning the Crop is greater in this Way of raiſing them than in any other, becauſe they will riſe more irregularly; and when they are very thick in ſome Parts, and other Spots are entirely vacant, as will be the Caſe, they ſhould be taken up and tranſplanted. The Earth being trod very much, and not broken up, requires this hoeing alſo, for otherwiſe it will be too hard. It anſwers the Purpoſe of the Seeds, becauſe the Peaſe have made it mellow.

Another very uſeful Way of raiſing a Winter Crop of Turneps, is upon a Piece of Ground where there have been Beans: but in this Caſe the Method is to plow up the Land once, and then harrow in the Turnep Seed. Either after Beans, or a Crop of any Kind of Corn where it has grown thick, the Ground is ſo hollow, that once plowing does very well to prepare it for Turneps; and by any of theſe Methods, if the Winter prove tolerably mild, there is no Doubt of a profitable Crop, but otherwiſe theſe late ſown Turneps frequently ſuffer.

CHAP. V.

Of the Potatoe.

THE Potatoe is an extreamly uſeful Root, and one that may very properly be cultivated in Fields. It is indeed fitter for the great Extent and plain Faſhion of a Field, than for the narrow Compaſs and divided Beds of a Garden, when we conſider its prodigious ſpreading. 'Tis but lately we have informed ourſelves properly of its Culture; and the more we know of that, the more Reaſon we ſee to baniſh it the Garden, and introduce it into the Field. It is hardy enough to bear the Expoſure, and it requires no great Charge in the Culture and Management; why then ſhould we limit it to the Garden, every Particular ſpeaks for its being given into the Hands of the Farmer, eſpecially when near large Towns, though every where there will be a great Demand. We ſhall therefore lay him down ſuch a Method for their Management, that he cannot fail, by obſerving it ſtrictly, to meet with a Succeſs that will make him keep up the Culture of this Root at all Times.

The Potatoe is a Plant of a ſingular Form and Manner of Growth: the Botanical Writers refer it to the Nightſhade Kind, calling it Nightſhade with the tuberous eatable Root. It is ſingular, that one of the moſt innocent Plants in the World, ſhould belong to a Claſs naturally and generally poiſonous, but theſe are Matters wherewith the Farmer has no Concern.

The Root of the Potatoe is compoſed of ſeveral large roundiſh Lumps, joined to one another by Means of Strings, and ſpreading a great Way in every Direction. The Stalks are numerous, three Foot high, branched, and full of Leaves; theſe are divided into ſeveral Parts, or each is compoſed of ſeveral Pairs of ſmaller, with an odd one at the End, but the Diviſion or Diſpoſition is irregular. The Flowers are large, and either of a duſky purpliſh Hue, or white, this being a trifling Variety, from which, as alſo the Colour of the Outſide Skin of the Roots, the Potatoe is divided into two Kinds, under the Name of the red and white: the Fruit is a large Berry.

We had this Plant originally from North America, and at this Time raiſe it in vaſt Plenty, and to a very great Profit. It is in a Manner the Food of the common People of Ireland; and is cultivated in Lancashire, and ſome other Parts of England, in vaſt Quantities. Our Intent is to make it more univerſal.

CHAP. VI.

Of the Soil for Potatoes, and the Manner of planting them.

MORE depends upon the chuſing a proper Soil for Potatoes, than for almoſt any other Root. Not but it is hardy, and will live any where, but it will not ſpread and propagate its Roots, unleſs the Soil ſuits. It is the Farmer's Intereſt to conſider this Particular in the moſt careful Manner.

There are but few Soils that will anſwer, in the right Manner, to the Potatoe; and thoſe that do, yield ſuch a prodigious Encreaſe, that on both Occaſions it is worth conſidering ſtrictly. The firſt Quality the Soil for Potatoe muſt have is Freedom and Openneſs, the ſecond is Richneſs, and the third a due Degree of Moiſture. This ſhews us that the beſt Soil of all for them is a mellow Earth, or good fine Mould, in the Condition wherein we moſt frequently ſee it, which is light, deep, and with ſome Moiſture; this points out a Part of the Kingdom for the Propagation of Potatoes, where they are very little regarded at preſent, the Northern Edge of Northamptonshire, and the adjacent Country. They have there this Soil in great Perfection, it is in ſome Places too wet, but there it would not

anſwer, the Place is where the Moiſture is moderate.

After the mellow and pure Earth, the Soil moſt favourable next is a rich Loam: this will ſupply them very well alone, if it be of the richeſt Kind of this Earth, but if not it is to be mended by Dung.

By this Direction as to the Soil the Farmer is to chuſe, he will know what he is to avoid; and firſt of all Clay is to be ſhunned, becauſe it will not ſuffer the Roots to ſpread; and Gravel, becauſe it will not ſupply them with Nouriſhment. Chalky Soils are alſo improper for the ſame Reaſons as Gravel, becauſe there wants Nouriſhment; as to the ſandy Kind they fall under the ſame Fault of Poorneſs, but they are open and free for the ſpreading of the Roots; and on ſome Grounds of this Kind, that have not been too abſolute a Sand, improved a little with Manure, I have ſeen very good Potatoes.

The red Potatoe ſucceeds beſt upon the ſandy Soil: but it never equals that on the rich Loam, leſs ſtill that on the mellow Earth. The different Effects of the Soils we have named are theſe, the Clay will not let the Roots ſpread; and the ſandy, though they give the ſpreading Room, will not feed them ſufficiently; the light mellow Earth produces therefore the largeſt and the moſt numerous Roots.

There may be an eaſier Improvement made in the ſandy Soil, than on any other for this Uſe. The laying on, from time to time, a proper Manure, will bring it into a good Condition, as one naturally fine. The beſt Manure is rotten Dung and the Mud of Ponds, this, mixed in a good Proportion, and laid on freely, will bring a Piece of ſandy Ground, that has any natural Richneſs of its own, into the Condition of the fineſt loamy Soil whatſoever; and there is but one, as we have ſhewn, ſuperior to that for the raiſing this Root well.

The Soil being choſen the Potatoe is to be planted, and in the doing that there is no great Difficulty; however, the Farmer muſt exactly obſerve the Directions, or he will fail in his Crop.

This being a Kind of Garden Root, let the Garden Practice be ſo far obſerved, that the Ground be well broken and prepared for the Reception. Let it be plowed in a careful Manner, conſiderably deep, and ſo as to break the whole Soil.

Let there be Trenches or Furrows cut acroſs the Field, ſix Inches deep, and a Foot aſunder; in theſe the Farmer is to lay regularly and carefully, the ſmalleſt Roots of Potatoes he can get, but with a very particular Care that they be freſh and fine. They muſt be placed in theſe Trenches ſix Inches from one another, and covered up by harrowing the Ground all over.

This is to be done in the latter End of February, and the Land is to be left in this even Condition till the Potatoes ſhoot, and the Weeds among them.

When theſe are up at ſuch a Height that they can be well diſtinguiſhed from the Shoots of the Potatoe, the Hoers are to be ſent into the Field, to cut them all down; and in doing this they will break and divide the Surface of the Ground ſo, that the Rains and Dews will get in, and the Crop thrive upon it immediately.

When the Weeds have once again got up to a Height, as they ſoon will from the Wet and Warmth of Spring, the Hoers are to go in again and clear all away.

After this no more Care is requiſite, the Stalks of the Potatoe will now be ſo high and ſo ſtrong, that they will ſuffer no more Weeds to grow among them.

This is all the Culture and all the Care the Potatoe requires; and nothing can be more eaſy. Here is no particular Expence in preparing the Ground, no great Charge of Stock or Labour; and there is no Hazard of Succeſs. The Sale is certain, and the Profit abſolutely very great. One Summer brings the Crop to Perfection, and there is no one Shadow of a Reaſon againſt the Farmer's raiſing them.

CHAP. VII.

Of preſerving Potatoes.

OUR Crop has been put into the Ground in the End of February, and it requires no more Time for its Encreaſe than to the latter End of September. Indeed no more than this can be allowed it, for the Potatoe ſhould always be taken out of the Earth, before there be a Poſſibility of Froſts that could hurt it. During the Summer it is free from any Danger, and in Autumn it is to be taken out of the Ground.

Toward the Middle of September let the Farmer begin to take up his Potatoes, and let him begin with that Part of the Field that lies moſt expoſed, leaving till afterwards that Part which is moſt ſheltered: he is thus to begin and to continue taking them up, Parcel after Parcel, once in two or three Days, as there is a Demand for them: but when he perceives the Ground firſt affected to any Depth by the Froſt, he muſt at once get up all the Remainder, for this is an Accident that will always hurt them.

As he will perceive the Seaſon of the Froſt approaching, he muſt prepare for it by providing a Place where to put his Potatoes, when he ſhall take them up. A Cellar, with a good Quantity of Sand, will anſwer this Purpoſe, and he will thus be able to preſerve them from Froſt: taking out what he has a Demand for, as he wants them, and reſerving the ſmalleſt, which will bring him leaſt at Market, for planting in the Spring.

This is the whole Care requiſite. As to the Produce it will be greater than thoſe can eaſily believe, who are not much accuſtomed to ſuch Things: it will depend upon the Soil, as we have obſerved already, but the Difference is ſo great, that the Expence of well dividing and breaking the Land by Tillage, and well enriching it by Manure where requiſite, will be very amply returned. The Size as well as Number depending on theſe Articles.

Ten tolerably large Potatoes is but a moderate Produce, from each ſmall Root that was planted in Spring; when the Ground is more favourable, thirteen or fourteen handſome ones; and on

counting, with the beſt poſſible Exactneſs, in a Field of Mr. RYDER's near THORPE, where every needful Caution had been taken, we computed this Year, 1746. that there were in general eighteen large and fine Potatoes for every ſmall Root planted. This, for a ſeven Month's Encreaſe, is very great; but Nature has in all Things provided, that whatever is moſt uſeful is moſt abundant.

The Conſequence of the Froſt taking the Potatoe, is a Kind of Diſſolution of its Subſtance, it runs to Water and rots.

The Approach of Froſts is a plain Direction, but the Decay of the Stalks, and the Condition of the Plant, will not fail to give the Farmer an earlier Notice. About the Middle of SEPTEMBER the Plant entirely ripens, and after that it quickly fades. The firſt Froſts which we do not feel, affect Plants, and in this Caſe they attack the Stalk and Leaves, before they penetrate the Ground ſo as to come near the Root. When the Farmer ſees the Leaves yellow, and the Berries of a dead ripe Colour and dropping, he may take Notice that the firſt Appearance of Ripeneſs in the Root is come. Let him begin to take up at that Time, and continue till all are out of the Ground.

It has been propoſed, by ſome who are fond of Schemes, and preſume to call any Practice that is new, an Improvement of Huſbandry, to cut off the Tops of the Potatoe as ſoon as they grow poor and fade, in order to preſerve the Root from Froſts. I have ſeen this tried, and it is fit I warn the Farmer from repeating ſuch a Project. It let in the Froſt to the Roots where I ſaw it experienced, much ſooner and more powerfully than it otherwiſe would have been, and the Conſequence was the Loſs of great Part of a very good Crop of Roots.

The Tops in this Inſtance were mowed down very clean with a Scythe, and there could be no better Way propoſed, but the Effect was juſt contrary to the Improver's Expectation, though very conformable to what might have been expected from Reaſon, for certainly Nature here is the beſt Adviſer.

The Potatoe very difficultly preſerves itſelf againſt the firſt Froſts of the Winter, but it will be ſheltered by the Quantity of dead Stalks and Leaves of its own, that lie upon the Ground; which will ſerve as the laying of Straw and Peaſe Haulm about early Plants, a Practice very well known for its Effects by all Gardeners: then, on the other hand, the cutting off the Stalks not only denies the Roots the Protection and Defence of their Covering intended by Nature, but lets in the Froſt directly to them, through the cut Part of the Stalks. This is an Effect ſo agreeable to Reaſon, that one would wonder the other Thought could ever have entered into the Head of any Perſon in the World.

The Advantage of the Potatoe lying as long in the Ground as may be, is that it all the Time is encreaſing in Bigneſs, at leaſt till Froſts come, and the Encreaſe in Bigneſs is Encreaſe in Value.

Some have ventured their Potatoes in the Ground all Winter, covering them with Fern and other ſuch Matters, beſide their own Straw; but this is hazardous, and of no Uſe. The Potatoes may thus be preſerved through the Winter, but they will not grow in the leaſt, and there is ſome Danger that they may periſh in ſpite of all the Covering. The Nature of the Field muſt finally determine the Farmer who is enclined to this Expedient, whether he ſhall venture upon it or no, for there may be Differences in Soil and Expoſure, very eſſential on this Head. The more Wet there is in the Grounds the greater the Danger; the ſandy Soils therefore are fitteſt for this Purpoſe. A Field may be ſo ſituated, and of ſuch a Soil, that the Ground may ſerve as Sand, and the Encloſure keep it as warm as a Cellar; but in this Caſe there is no Advantage, though there may be little Hazard; ſome Sand in a Cellar keeps them more ſecurely, and they will no more grow in the Field than there.

When the Time of taking the Potatoes up is come, the Farmer muſt ſend into the Ground a Man or more, and to every Man one or two Women, or grown up Children; the Man muſt have a ſtrong three tined Pitch Fork, with which he is to dig up the Potatoes, and the Women and Children are to follow him, picking them up, and carrying to Heaps that they may be conveniently taken off the Ground together.

When they are got Home they muſt be cleaned, and lightly waſhed, and after this dried two or three Days in the Sun, they will then be fit for Market or for keeping.

Beſide the Way of keeping in a Cellar, Potatoes when the Quantity is very large, may be preſerved during the Winter, in a Pit made in the Ground, but this muſt be done with great Care and Circumſpection. The Farmer who intends this Method, muſt ſee for a dry Place, where the Soil is of a warm Nature, and there is good Shelter. Here he muſt dig his Pit or Ditch, and the beſt Method is to make it in Form of a Ditch, three Foot wide, five Foot deep, and line it on the Sides and Bottom with dry Wheat Straw. This done the Potatoes are to be carefully put in till the Ditch, which is to be long in proportion to the Quantity, be full up to the Level of the Ground; a Quantity of Straw is then to be put over them, and on this is to be raiſed a Ridge of very dry Earth. In this Manner they will keep throughout the Winter, and be ready on all Occaſions.

Where the Ground is a perfectly dry Sand or Gravel underneath, the Potatoes may be kept very well in Pits, dug for that Purpoſe; and thus they are preſerved with Sand for the Supply of the LONDON Markets, in thoſe Parts of ESSEX and other Counties where they raiſe moſt for that Purpoſe.

For the Sake of the Farmer who ſhall deſign to have large Concerns in this Article, I ſhall give ſome ſhort Hints reſpecting a particular Kind of the Potatoe, which though leſs obſerved by the Planters than it deſerves, has Advantages quite ſeparate from the others.

We diſtinguiſh the Potatoes into two Kinds, the white and the red; but we may very well add a third, which is this of which I ſpeak, under the Name of the yellow.

Whoever is accuſtomed to deal largely in this Root, muſt have obſerved that there is a yellow Kind,

Kind, which is uſually very large and thin ſkinned. This though leſs known among us, or leſs regarded, is kept ſeparate by the Irish, who are more uſed to this Root, and prefer it to both. Its Size is not the only Difference, or the only Advantage.

We have ſeen that the great Danger in Potatoes, is the loſing them by Froſts: the Reaſon of this is their ſhallow rooting, though we plant the firſt Roots at ſix Inches deep, thoſe which ſpread from them will riſe to the Surface, and it is this expoſes them ſo greatly to the Froſts. It is particular to the yellow Potatoe, that it roots deep: the ſeveral new Roots are generally deeper in the Ground, than the firſt was planted. This is a vaſt Advantage, for they will be ſafe when the others are deſtroyed. Every one knows the general Uſe of Potatoes among the Irish: they never take them out of the Ground in Winter, but as they want them, in many Places, but it is becauſe they propagate this yellow Kind; for the others wloud be deſtroyed often there, as well as here, becauſe of their ſhallow rooting.

This Kind is in Ireland called the Munster Potatoe.

This Kind will laſt in the Ground a great many Years, becauſe of its deep rooting; but though the Practice in Ireland, and in Lancashire in ſome Degree, authorizes this Method, I ſhall adviſe the Farmer utterly againſt it: I have always ſeen this Root, like other Things, flouriſh beſt in a new Plantation, for which Reaſon I ſhall adviſe the Farmer always to clear, and new till the Ground once in three Years, that he may have its full Advantage. I ſhall alſo adviſe him againſt the common Practice in ſome Places of planting Pieces of Potatoes, inſtead of whole Roots; it is true that Pieces with any Eye to them will grow, but whole Roots always ſucceed much better.

CHAP. VIII.

Of Carrots.

THE Carrot is the only Root we ſhall mention farther in this Place, reſerving ſuch as are leſs commonly known, to the ſucceeding Book. This is a Root as fit for the Field as the Garden; requiring very little Culture, and producing a very great Profit to the Planter. It is hardy enough to ſtand all the Attacks of Cold, and other natural Accidents. And though in ſome Parts of the Kingdom, only hitherto kept in Fields, is very worthy to be introduced in the Huſbandman's Catalogue every where, and is indeed, for many Reaſons, fitter for the Field than the Garden.

The Root of the Carrot is long and thick, varying in Colour from the deepeſt Orange to the paleſt Straw, and having every Tinge of red or yellow. The Leaves are large, and divided very beautifully into a Multitude of minute Parts. The Stalk, when the Carrot gets to flowering, riſes in the Midſt of the Leaves, and is four Foot high. The Leaves ſtand irregularly on it, and are like thoſe at the Root, only ſmaller and paler. The Flowers are little and white, they ſtand in a large rounded hollow Tuft at the Tops of the Branches, and are followed by Seeds that are numerous, ſmall, pale coloured, light, and rough.

This is the general Deſcription of the Carrot, which from its Flowers growing in a Tuft, like an Umbrella, though leſs ſo than many others, is one of thoſe called by Authors Umbelliferous Plants.

We have obſerved that there is a Variety of Colour in the Roots of the Carrot, from the deepeſt Orange to the paleſt Straw, or Sulphur Colour: the Gardeners have hence, according to their Cuſtom, made what they call three principal Kinds of Carrot, taking the three moſt diſtinct Degrees of Colour, the deepeſt, the middle, and the paleſt. Theſe they call, 1. The dark red Carrot. 2. The Orange Carrot. And, 3. The white Carrot. The firſt and laſt of theſe Terms are ſomewhat improper, the firſt Kind being only a very deep Orange, and the other only a very pale Yellow.

The firſt is the moſt generally eſteemed: People who are critical in theſe Matters, uſually preferring the deepeſt coloured Carrots; the white Kind is more common in France and Italy than here; and though Cuſtom give the Preference, the contrary Way is the ſweeteſt and fineſt flavoured of them all.

This however is not to influence the Farmer in his Choice. He is to cultivate not that which is beſt, but what People think ſo; and therefore he is to chuſe the deep red, commonly called the Sandwich Carrot.

This, with the Management we ſhall direct in the enſuing Chapters, will never fail to return to the Huſbandman a very conſiderable Profit, at a very moderate Expence.

CHAP. IX.

Of the Soil for Carrots, and its Preparation.

THE firſt Thing a Farmer muſt do who intends to plant Carrots, muſt be to examine whether he have proper Ground, for without this there is no ſucceeding: thoſe Plants whoſe profitable Part is the Leaf or Ear, may be raiſed on very different Soils, by the Aſſiſtance of Manure; but theſe which depend on the Root can never come to any thing, when the Ground is not proper in its own Nature.

Three Things are requiſite in Land for Carrots. It muſt be deep, rich, and dry. Theſe do not ſo often concur as the Farmer might be inclined to wiſh. Deep and dry is common, becauſe all ſandy Soils have it; and therefore in general they are fit for Carrots; but to be rich withal is the compleating of the Buſineſs: the other will give Room to penetrate and Warmth to cheriſh, but when Nouriſhment in Abundance is joined with theſe, in the Richneſs of the Land, 'tis then the Ground is compleatly proper.

For this Reaſon a fine rich deep Garden Mould, where there is not too much Moiſture, is very proper for them; but too much Moiſture is the com-

common Fault of this Kind of Ground. Therefore to ſpeak from Experience, I ſhall declare the very beſt Soil for Carrots to be a rich Loam: that is, a dry Earth, in which there is a great deal of Sand, a good Quantity of mellow Earth, and a very little Portion of the Clay. Some of this there is in all Loams, but the leſs the better on this Occaſion; I have ſeen excellent Land for Carrots in NORTHAMPTONSHIRE and LINCOLNSHIRE, upon thoſe riſing Grounds adjoining to the Fens, and juſt raiſed above them. And in SURRY and SUSSEX there are vaſt Tracts of Ground left in a Manner deſart, which would yield a great Profit from Carrots. It is in theſe Inſtances we ſee the vaſt Advantages that would ariſe from making the Knowledge of Huſbandry univerſal; the putting into the Thoughts of Farmers in one Place, what is the profitable Practice of another on like Soils. We hope this Work will be inſtrumental to that excellent Purpoſe.

The Soil being choſen, the Preparation of it conſiſts in two Articles, the enriching it by Manure, and the breaking it deep by Tillage. All Land for this Purpoſe will anſwer the better, the more Care is taken of it in this Reſpect; and we ſhall ſhew the Manner of doing it; for otherwiſe all the Expence may be worſe for the Crop, than if the Land had been left in its natural Condition.

The Times of theſe Preparations are to be very different; as to the plowing and dividing of the Land, that ſhould be done juſt before the Seed is ſown; but the Manure muſt be laid on a Year before. This will occaſion no Loſs of Time with the judicious Farmer, for he may have a vaſt Crop of ſome ſlight rooting Plant, as the ſmall Pulſes mentioned in our laſt Chapter, or ſuch others which will mellow the Ground by ſhading it with their Stalks, at the ſame Time that they yield him a great Encreaſe, without exhauſting the Effect of his Manure. After this the Land being plowed up for Carrots, will be in the beſt poſſible Condition to ſupport them.

The Reaſon of this Management of the Dung is very plain: the Carrot will have great Advantage from the Richneſs it gives the Ground, for the richer that is the larger they will be; but then freſh Dung always ſubjects the Land to be full of Worms; and this is what ſhould be feared more than almoſt any other Accident, in a Carrot Plantation, for theſe Roots are a very luſcious Food for thoſe Inſects; and when Worm-eaten they are worth little.

For this Reaſon none but old and well rotted Dung ſhould be uſed; and that ſhould be laid on the Year before.

When the Grouud, naturally of a rich, light, and warm Nature, is thus improved by a well mixed and well rotted Manure, it is to be wrought for Carrots.

According to the old Huſbandry this could only be done by Hand, but this is an Article wherein we ſhall propoſe to the Farmer great Improvement. The Ground requires to be dug very deep for Carrots, becauſe their whole Value is their Length and Straitneſs, which they will never attain if they have not a free Paſſage down for their Roots. For this Reaſon the old Practice was to dig the Ground with Spades, and this was reaſonable, the Carrots requiring it to be well broken two Spit deep, and no Plow then in Uſe anſwering this Purpoſe.

This was in a Manner bringing Gardening into the Field; but that is not what we mean by recommending to the Huſbandman the Culture of Garden Roots. If they can only be propagated in Fields at the ſame Charge as in Gardens, there will be little Profit to him, and it is only leading him out of his Way; we ſhould not have named the Carrot as one of the Roots he may cultivate to Advantage, had we not intended to put him in a Way of doing it with the proper Implements of his Profeſſion.

The four coultered Plow will, in this Caſe, perfectly well anſwer the Purpoſe of the Spade; and this at one Stroke reduces the whole Expence, and throws the Article directly in the Way of the Farmer.

When this Plow is well managed it cuts full two Spit deep, ſo that it perfectly anſwers the Purpoſe of this expenſive digging by Hand; and by the Means of its numerous Coulters cuts, divides, and breaks the whole Subſtance of the Soil, even better than the Spade.

CHAP. X.

Of ſowing of Carrots.

THE Farmer is to make it his firſt Care, when he thinks of ſowing Carrots, to procure good Seed: this he will know by its ſweet Smell, its pale Colour, and its Roughneſs: if it be muſty or broken, 'tis damaged or old, and in either Caſe will greatly diſappoint him.

The Seed being choſen, he is to get to work upon his Ground in the Beginning of MARCH. Gardeners ſow Carrots in a Manner the Year round, that they may have Crops of young ones one under another; but this the Farmer has nothing to do with. He ſows them for two Conſiderations, which are, to have large Roots for Market, and to get good Seed from proper Parts of his Ground, which is alſo very abundantly produced, and yields a very large Price.

The Beginning of MARCH therefore is the Time when he is to prepare by plowing. His own Reaſon will direct him never to chuſe a ſtony Soil for this Root; but he muſt have a Couple of Women or Boys to follow the Plow, to pick up any looſe Stone or other hard Matter that may chance to be turned up.

When the Ground is thus deeply cut up and picked, the Harrows are to be ſent in, and the Surface is to be well leveled like the beſt prepared Border in a Garden: this done it is ready for the ſowing. When the Seed is a material Conſideration the Plants are to be kept farther diſtant, and the drieſt and warmeſt Soils are beſt for this Purpoſe.

There muſt be a great deal of Care in ſowing Carrot Seed, and a proper Day muſt be choſen, otherwiſe it will be impoſſible to do it as it ſhould be. The Weather muſt be ſtill and calm, and the Perſon who ſows them muſt go over all the Ground carefully, with the Seeds in his Apron, and muſt ſpread them by Hand a few at a

Time, and he muſt take Care that they fall ſeparate; for their rough Surfaces make them very apt to hang together. When any of them cling to one another, he muſt rub them in his Hands before he delivers them to the Ground, and by that Means thoroughly ſeparate them. His next Care is to ſee that they fall tolerably regular. And as to the Manner of their lying; one about every three Inches is the beſt Method, not that the Carrots are to ſtand ſo cloſe, but there ſhould be Seeds enough ſown that Accidents may be allowed for, and the Plants thinned by hoeing.

As ſoon as ever the Seed is upon the Ground, let a good heavy Roller be brought on, and the whole Field well rolled over with it. This ſettles the Seeds in their Places, and prevents the Effect of the Winds, which would ſpread them irregularly ſhould any riſe before they are thus fixed down.

This done, a very fine and ſhort toothed Harrow ſhould be drawn lightly over the Ground, and then the Article of Sowing is finiſhed. In theſe fine and well prepared Lands, the Harrow does not bury the Seed as it will where there are great Clods to be torn up. In this Caſe the rolling and harrowing only anſwers to the treading in, and raking of the Seed in the common Practice of Gardening; and they ſhoot up as regularly this Way as the other.

CHAP. XI.

Of managing a Crop of Carrots, and their Uſe.

THE Seed being in the Ground, is to be left to Nature for its ſhooting, and as ſoon as it is up, and got to ſome little Height, the Hand Hoers are to be ſent into the Field. They muſt have Orders to cut up all Weeds, and thin the Plants. The proper Diſtance at which they ſhould be left, is about ſeven Inches from one another; and thus they are to ſtand till they come to their Perfection; for the Ground having been once well weeded in this Manner, the Carrots will grow ſo vigorouſly, that their Leaves meeting every where one with another, will overſpread the whole Ground, and let no more grow between them.

The Carrots thus left to themſelves will grow to a very good Size by the End of Autumn, and they will thrive the better if Quantities are pulled for Market, from time to time, when they are big enough to be ſaleable, not drawing theſe all in one Place, but from thoſe Cluſters where they happen to ſtand thickeſt.

Toward the End of November the Leaves of the Carrots will begin to decay. The Farmer will know this by their becoming yellowiſh or reddiſh, this is his Notice for taking up the Roots. The Carrot like the Potatoe ſhould be taken up in the Beginning of Winter, and laid by in dry Sand, in which Manner they will always be kept ready for the Market.

The Froſt hurts Carrots in the ſame Manner as Potatoes, though not ſo early or ſo readily; therefore, as ſoon as that Time of the Year approaches, when they are to be expoſed to the Hazard, they muſt be taken out of the Ground and laid up in Sand, which Froſt does not ſo much effect as any other earthy Subſtance; and this muſt be in a dry Place, where they are defended from it in the beſt Manner.

This is the whole Management of the Carrot; it is eaſy and familiar in the greateſt Degree; and the Profit is great and certain: there is always a Market for this Root, and the Price is ſuch that the Profit proportioned to the Land and Labour is very great.

We have ſaid, in the Beginning of this Account of the Carrot, that the Root is not the only Article by which it is ſerviceable to the Farmer, for that there is a great deal of Profit from the Seed. This is the Produce of the ſecond Year, and for this Purpoſe the Plants may be either left in the Ground during the Winter, or ſet in again in the Beginning of Spring.

The Gardeners uſe the latter Method, but the Farmer will find the other beſt, becauſe there is leſs Trouble; only he muſt take Care that he chuſe the drieſt and warmeſt Part of the Field for that Purpoſe.

If the Carrots for Seed are planted, after being kept in Sand during the Winter, the largeſt and fineſt Roots muſt be choſen for that Purpoſe: in the other Method, of letting them ſtand through the Winter for that Uſe, the moſt vigorous Plants muſt be left. Theſe are to be kept at a due Diſtance, by ſeparating them in drawing the others. The drieſt and warmeſt, and beſt ſheltered Part of the Field, muſt be choſen, and they muſt be left at about a Foot aſunder, in this Condition they will gather Strength during Winter; the Stalks will riſe early the enſuing Summer; and the Seeds will ripen in Abundance about the Middle of August.

When thoroughly ripe the Plants are to be cut down with an Hook, and laid in the Sun and Air four Days to dry, frequently turning them. After this they are to be thraſhed, or the Seeds are to be beaten out of them; and when ſeparate they are to be aired and dried ſeveral Days before they are put up for Sale; they will thus be perfectly fine, ſweet, and well coloured, and will bring a large Price.

End of the EIGHTH BOOK.

A

Compleat Body of Husbandry.

BOOK IX.

Of several advantageous Articles in Husbandry, which are less universal than the others.

Chap.

1. *Of Hops.*
2. *Of the several Kinds of Hops.*
3. *Of the proper Land for a Hop Ground.*
4. *Of placing the Hills.*

The INTRODUCTION.

THE Title we prefix to the present Part of our Undertaking, shews the Sense we entertain of its Importance, in a Work of this Kind: 'tis to the Misfortune of the Husbandman, when any thing that is in Reality advantageous, is not universally known, or generally practised. We shall recount several Kinds of Crops under this Head, that deserve to be made common throughout the Kingdom; and shall lay down such Rules for their several Managements, that those who try carefully cannot miss of Success.

We shall begin with one Species, the Value and Profits of which are sufficiently known, in those Parts of the Kingdom where it is commonly raised: this is the Hop; and this, as it may be cultivated to the great Benefit of the Farmer, in many others, we shall hope to render more general.

CHAP. I.

Of Hops.

THERE are few Things by which the Husbandman may enrich himself more than Hops; but there requires a general Knowledge of their Nature, the Ground they suit, and the Accidents to which they are liable, in order to his entering upon the Design with a rational Prospect of Success. The Management of them in the Planting, Growth, and Gathering, is also a peculiar Branch of the Business. This is at present confined to a few Counties, but as there are many other Places where it will succeed as well, we shall endeavour to make it universal.

The Hop is a tall weak Plant, that climbs by the Means of more substantial Things: naturally it runs up Hedges, and Art supplies it with Poles for this Purpose.

The Root consists of thick black Strings, the first Shoots are thick, soft, and tender, like those of Asparagus, and are eaten in the same Manner. The Stalks, as they rise higher, become rough and firm in their Substance. The Leaves are large and rough, and are divided like those of the Vine. And the Flowers and Fruit grow upon separate Plants. This is not singular to the Hop, for Hemp grows in the same Manner, as also Spinage, and many other Herbs less regarded. The Flowers are small, greenish, and trifling. The Fruit is what we call the Hop, for the Sake of which the Plant is raised.

The Flowers being not succeeded by any Fruit, are called Male Flowers, this being the customary Expression in treating of such Plants. Each consists of five, oblong, blunt, and hollow Leaves, within which stand five extreamly short and fine Threads, each topped with a little Knob or Button.

The Fruit which grows in the Place of a Flower in the Female Hop, consists of a general Cover or Case, divided into four Parts. Each separate one consists of four Leaves, and is of an oval Figure, and contains eight Seeds in their proper Receptacle; so that the whole Hop contains thirty-two Seeds. The Case in which each Seed is ripened, is of an oval Form, and made of one little Leaf, in which rises a little Button, terminated by a slender Filament, and divided into two spreading Threads. This

Button becomes the Seed, which when ripe is roundiſh, covered with a Kind of Coat, and is lodged in the Bottom of the Caſe.

This is the exact Structure of the common Hop. Eight of theſe Seeds within Caſes, are encloſed in each Diviſion of the general Fruit, four of which make up the whole.

The Flowers of the Male Plant are not uſeleſs, as the Vulgar ſuppoſe. Though they produce no Fruit themſelves, they are neceſſary to the ripening of the others. Every Fruit has its Rudiment in the Bottom of the Flower, and the Duſt in the little Heads in the Middle impregnate it, otherwiſe it never ripens. In moſt Plants theſe little Heads are in the ſame Flower with the Rudiment of the Fruit or Seed, as in the Tulip and others: in ſome they grow in ſeparate Flowers, upon the ſame Stalks; this we ſee in Melons and Cucumbers: and in ſome, the Flowers having theſe little Heads in them, grow on one Plant, and the Rudiment of the Fruit in another of the ſame Kind. This is the Caſe in Hops, and in Hemp, Spinage, &c. as we have ſaid already. This is the Courſe of Nature in providing for the ripening of the Fruit of this uſeful Plant.

It does not appear by any thing in the Works of the Antients, that they were acquainted with the Hop. PLINY is the firſt who names it, and that only as a Sallad Herb. But we are not to wonder we read nothing of it before his Time. The GREEKS ſtudied Utility; and the Uſe of the Hop in Malt Liquors, which is its great Service at this Time, was not known to them. They had Malt Drinks, but they were not made for keeping; Lupulus is the Name by which it is called by PLINY, and others; but it is become a Faſhion lately, to call it Humulus.

The Hop is a wild Plant in ENGLAND, and moſt other Parts of EUROPE, and it naturally loves a damp Soil at the Foot of a Hill, we find it in ſuch Places crawling up the Buſhes in Hedges; but its Value occaſions it to be cultivated with Care, in Grounds choſen for that Purpoſe. We ſhall proceed to give the practical Huſbandman an Account of it.

CHAP. II.

Of the ſeveral Kinds of Hops.

TO ſpeak with Strictneſs there is but one Kind of Hop; for what are mentioned under different Names, whether among the Writers on Herbs, or the Planters, are only Varieties of the ſame Plant, as Culture and other Accidents have changed it. However, as ſome of theſe keep their Difference in planting, we who write for Utility, not Curioſity, may very well diſtinguiſh them according to the Cuſtom of others, into theſe ſeveral Sorts.

In Books we meet with an Account of the Male and the Female, of the wild and the Garden Hop. What is meant by the Male and Female we have ſhewn. As to the others, the Difference is only that made by proper Care, from the Plant in its natural Wildneſs.

When we ſpeak with the Planters, they tell us there are four Kinds of Hops. Theſe are the beſt Directors for the Huſbandman, and we ſhall therefore follow their Diviſion. The four Kinds are theſe: 1. The wild Garlick Hop. 2. The long and ſquare Garlick. 3. The long white. And 4. The oval. The firſt of theſe is what Authors call the wild Hop, the three others they confound together under the Name of cultivated Hops.

The wild Kind is poor, ſmall, and not worth Notice. The long and ſquare Garlick is a well taſted Hop. But 'tis ill-coloured, for which Reaſon it does not bring ſo good a Price; the Fault in this Reſpect is a Redneſs which it always has about the Stalk. The Long-white is the moſt beautiful Hop, and the moſt valuable, becauſe of its greater Encreaſe, and the next to theſe are the Oval; theſe are ſhorter than the Long-white, but otherwiſe equal in Colour and Flavour.

It would be natural to ſay that none but the Long-white ſhould be cultivated, becauſe theſe are the beſt and moſt plentiful in the Produce, but 'tis not every Land that will bear them. They will live in any, but to thrive they require what is very good, and a thriving Crop of the long and ſquare Garlick, is better than a ſtarved one of the other.

Therefore let the Huſbandman who ſhall think of raiſing Hops, ſuit the Kind to his Land. All Hops love a very mellow rich Soil, but the long Garlick being moſt of the Nature of the wild Hop, will bear a poorer Ground better than the others.

The proper Soil for a Hop Ground is a rich Garden Mould. But as this is never found entire, we are to tell the Farmer that of its two general Mixtures, which are Sand and Clay, the Clay makes it unfit for Hops; but the Sand, in a moderate Quantity, is not hurtful.

In order to plant Hops with any Proſpect of Succeſs, the Soil muſt be deep and well conditioned to the Bottom.

If the Ground on which the Huſbandman intends to raiſe his Hops be pure and fine Mould, let him plant the Long-white, and no other Kind. If it have a moderate Mixture of Sand, let him plant the Long-white and Oval together, for they will do very well in the ſame Ground. If it be much inclined to Clay he is not to uſe it for this Purpoſe, but if only ſomewhat clayey, and he will have it a Hop Ground, he muſt plant the long Garlick. Before the Huſbandman fixes upon his Deſign, let him not only examine the Condition and Depth of the Earth, but what is under it. The deepeſt Soil does not reach far, and in all Growths a great deal depends upon the Nature of the Bottom, but in none more than this. A Clay Bottom is too cold, and retains too much wet; and a gravelly Bottom lets it through too faſt, ſo that they have not enough to nouriſh them, for the Hop being a tall Plant requires a good Quantity of Moiſture. A loamy Bottom is the beſt. That Sort of Earth of which Bricks are made, is of a very fit Kind, and is a very common Bottom to the Soil in moſt Places. Let the upper Coat or Soil be light and rich, and it matters not for the Colour. The ESSEX Hop Grounds

are on a moory Land, which is black; and many of the Kentish are upon a whitiſh crumbly Soil, they ſucceed equally well, all that is required being a Quantity of good Ground, wherein the Roots can run with Eaſe, and find a due Quantity of Nouriſhment.

CHAP. III.

Of the proper Land for a Hop Ground.

WE have ſhewn, in a preceding Part of this Work, that Plants in general ſend their Roots deeper and farther in Search of Nouriſhment, than is commonly thought: none go deeper or farther than Hops; for this Reaſon, in preparing Land for them, if the upper Part be a great deal better than what is under it, as is generally the Caſe, the Work muſt be done in the Way of trenching, and the fine Part of the Soil buried undermoſt. What is at a Depth being much more eſſential to this Plant, than what is near the Surface.

When the Piece of Ground fixed upon for this Purpoſe is over moiſt, it muſt be laid up in high Ridges, to be well drained. And when it has been thus rightly managed at firſt, it muſt be kept in the ſame Condition, by keeping the Drains open and clear, otherwiſe the Roots will be deſtroyed in Winter.

We have obſerved that clayey Soils are to be avoided, and there are two others nearly as bad, theſe are, the gravelly and rocky. In neither of theſe Hops will ever anſwer, but in any others they may be raiſed; and if the worſer Kinds be planted on the more indifferent Lands, and the finer reſerved for the beſt, with due Care they will never fail.

Hops root ſo deep, and ſpread ſo far, and draw ſo large a Quantity of Nouriſhment, that they exhauſt a Land extreamly. They may therefore be planted after almoſt any other Growth, but no other will thrive after them except Trees, which root deeper, and ſpread farther than they.

For this Reaſon a Piece of Ground that has been exhauſted by other Crops, which do not root deep, will raiſe Hops very well, though an entire new Piece of Ground does better; if any one ſhould break up a Piece of Saintfoin for Hops, let the Soil be what it would, they would never proſper well, becauſe that Graſs having rooted as deep as they, had drained the Earth of its Nouriſhment ſo far as they can reach: but on the other hand, if a Piece of Corn Land that will no longer bear Crops without Refreſhments, be turned up for a Hop Ground, it will ſucceed very well if the Soil be proper, becauſe Corn roots ſuperficially, and the Earth at that Depth which Hops reach is left unexhauſted. But a Piece of Virgin Land is better than this, becauſe in that the fine unexhauſted Top of the Soil may be turned in under the other, and no Land can afford them ſuch excellent Nouriſhment.

Therefore let the Planter obſerve that he take the beſt Ground he can find, if he have his Choice; and knowing that it will be fit for Hops only a certain Time, and fit for no Crop afterwards, let him prepare accordingly.

Saintfoin, which roots deep, leaves Land in a very good Condition for Corn, becauſe it ſpreads very few Fibres near the Surface; but on the contrary, the Hop ſpreads its Roots deep and ſuperficially too, ſo that 'tis fit for nothing afterwards but Trees.

A good Piece of Land reduced from common Tillage, will ſupport Hops very well eight Years: a Piece of Virgin Earth, if the Soil and every other Circumſtance be favourable, will ſupport Hops twelve Years; but not longer to Advantage. Let the Planter take the proper Care therefore in Time.

When he has laid his Deſign for a Hop Ground, let him plant it alſo with Apple and Cherry Trees at the ſame Time.

Theſe will draw but little Nouriſhment while young, and therefore the Hops will very well ſtand twelve Years with Advantage. At the End of this Time the right Practice is to make a new Hop Ground in another Place. By this Time the Cherry Trees will bear. They will continue improving every Year for ſome time, and will laſt very well five and twenty Years; at the End of this Time they may be cut down, and the Apple Trees will be in fine Order.

Let it be remembered that the Hop, in its wild State, loves a ſheltered Place, at the Foot of a Hill; and let the Planter chuſe his Spot accordingly, for Nature is an excellent Guide. A Piece of Ground that lies low and warm, open to the South, and well defended by Trees on the other Quarters, is the favourable Spot for Hops; if the Soil be deep and good in ſuch a Piece of Ground, no Way of employing it can turn to ſo great Account. If ſuch a Sheltering is wanted naturally, it muſt be raiſed by Art, and there muſt be Water near. Theſe are the Requiſites.

CHAP. IV.

Of placing the Hills.

WHEN a Piece of Ground is fixed upon, which has all theſe Requiſites, and a proper Quantity of Plants of a Kind ſuited to its Nature, are in Readineſs to be taken up occaſionally for it, the Ground is to be prepared for their Reception.

Hops are planted on ſo many little Hills, and theſe are to be placed at ſuch Diſtances as are beſt ſuited to the Extent of the Ground, and the intended Manner of dreſſing.

If the Piece be ſmall, the Breaſt Plow or Spade muſt be uſed for dreſſing the Ground, when the Hops are upon it: but it is much better to ſet out with a larger Piece, and diſpoſe the Plantation for Horſehoeing.

Whichever Method be taken, Time and Pains are required to put the Ground in proper Order. October is the Seaſon for planting the Hops, but the preparing the Ground is the Buſineſs of a Month before. The firſt Thing that muſt be done is plowing it up, and laying it very even.

The

The Spade may anſwer this Purpoſe in a ſmall Piece of Ground, but larger are in all Reſpects better.

The Intent of this plowing or digging is to break the Ground very ſmall, and to a conſiderable Depth. The proper Plow therefore is the four coultered one, deſcribed before, ſet to its greateſt Pitch; in this Condition, with the Guidance of a ſkilful Plowman, it will cut two Spit deep, and tear the Ground all to Pieces the whole Way. When the Ground is thoroughly broke and divided by this Plow, let a Harrow be drawn over it; and laſt of all a light Roller. It will then be well broke, and will have an even Surface: this is the Condition wherein it is fit for laying out for the deſigned Plantation.

The next Thing is to determine what ſhall be the Diſtance of the Hills, and when this is ſettled a long Line is to be procured, and a Knot is to be tied in it by Meaſure, at every Diſtance that is ſettled for a Hill.

As to the Form that muſt be determined by the Ground, if that be ſmall, and the Spade or Breaſt Plow are to be uſed, then the beſt Method is the Quincunx, which diſpoſes the Hills in Lines, and leaves regular Alleys every Way between them, but in larger Grounds 'tis beſt in Squares.

The Line is to be drawn ſtrait acroſs the Ground, from Place to Place, according to the determined Diſtance, and a Stick is to be fixed down at every Knot. This marks the placing of the Hills.

When the Soil is thus turned and mixed together, the Planter will be better able to judge of it than before; and if it want Richneſs let him amend that Fault, by adding ſome good Stuff to the Places which are marked for the Hills; theſe being the Spots where the Plants are to be ſet.

It is very rarely that a Piece of Ground is ſo perfectly good, as not to admit of this Improvement, and as it is very great, and of no vaſt Expence or Difficulty, 'tis always worth while to do it.

We ſhall therefore adviſe the Huſbandman in general, to plant his Hops in a Compoſt, and the beſt Method of making it is this. Dig a Quantity of rich Virgin Mould, or other very good and fine Earth, proportioned to the Number of Hills that are to be raiſed; add to this one fourth Part the Quantity of very old and well rotted Dung, and about a tenth Part of ſharp Sand, let all this be well mixed and ſtand in Readineſs. Then at every Stick open a Hole two Foot deep, and a Foot and half ſquare, fill this with the Compoſt, and all is ready for the Plantation, which will thrive vaſtly the better for this previous Care.

We have not yet laid down any exact Direction for the Diſtance at which theſe Holes are to be opened, and indeed the Diſtance of the Hills is one of the niceſt Things in the whole Buſineſs. Neither can any general Rule be given about it; for the Nature of the Soil, and Extent of the Ground, and intended Manner of working, will make Variations. In general about eight Foot Diſtance is the neareſt they ſhould ſtand.

As we have ordered the Farmer to ſow more Seed upon his poor Land, than upon that which is rich, ſo in the planting the Hop Ground we ſhall follow the ſame Method, and adviſe him if the Soil be worſe than ordinary, to make his Hills at ſeven Foot Diſtance, and if it be very rich and fine to ſet them at nine Foot. If it be at any time found either in a new Ground or an old one, that it will nouriſh more Hops than there are upon it, the beſt Way is to add to the Number of Plants upon each Hill, and not to multiply the Hills. So that for this Reaſon the Planter need not be afraid he ſhall place them too diſtant.

CHAP. V.

Of planting the Hops.

THE Hills being thus prepared, are to be planted; and Care muſt be taken in the providing ſuch Sets as are excellent in their Kind. Let the Huſbandman truſt no Eye but his own for the Choice, and let him obſerve the following Cautions.

Firſt let him conſider the Kind, and next the Place where they have grown, for this is very eſſential. We have already ſaid what Kind ſuits each Soil, and let him take Care to follow that Direction firſt.

Next let him conſider the Soil from whence he has them; here there are two eſſential Points, which in a Manner contradict one another. 'Tis neceſſary he ſhould have the ſtrongeſt and moſt flouriſhing Sets he can procure, and 'tis beſt that he have them from a poorer Ground than his own. Let him be ſure they do not come from a richer Soil, for then they will certainly dwindle: but let him chuſe the ſtrongeſt Shoots of a middling Piece of Ground; for his Compoſt into which they are to be ſet will certainly exceed that in Richneſs, ſo that they will be forwarded for the firſt Shoot; and the whole Ground being newly ſtirred, they will ſpread their Roots without Difficulty, when they have ſhot them beyond its Extent.

When the Planter goes into a Ground for purchaſing his Sets, let him, after he has conſidered the Soil, examine the Height of the Hills. Nothing ſo ſtrengthens the Shoot of the Hop, as the raiſing the Hill high. Let him therefore chuſe them from ſuch Hills as have been moſt raiſed the preceding Year, and from ſuch as are fulleſt of Shoots; becauſe this alſo is a Sign that the Roots whence they come are hearty; and where there are moſt of them, they are always, while thus young, the moſt vigorous.

Having fixed upon the Hills let him fix upon the largeſt Sets, and ſee them taken carefully up, they ſhould be about ten Inches long, and have four Joints or Buds. When a proper Quantity are taken up, according to the Number of Hills there are to be, let them be laid in the Ground in a cold and damp Place, and taken out as the Holes are prepared for their Reception.

In the Center of every Hole that has been filled up with the Compoſt, let there be a ſquare Opening made of a Foot deep, throwing up the

the Earth on the Sides. Into this Hole, which muſt be the full Foot deep, put four of the Sets. Place one at each Corner. Set them upright, with the Top juſt level with the Surface of the Ground, and then throw in the Earth that had been dug out, fixing it well about the Roots. Cover the Tops about two Inches with the fineſt and lighteſt of the Mould, and the Hole is finiſhed. Thus the Foundation of one Hill is laid.

In the ſame Manner plant four Sets in each Hole, covering their Tops, and burying the whole Set ſtrait, and cloſing the Mould about the Roots.

About a thouſand Hills will very well ſtand in an Acre of Ground, ſuppoſing it of the middling Kind, and this is the whole Trouble of planting them. The Expence is not great, for the Sets are ſold cheap enough, and an expert Perſon makes quick Work in ſetting them.

The Huſbandman ſees the Eaſe with which Hops are raiſed, we ſhall now tell him the Encouragement he has to plant them. No Produce whatſoever is equal to them: they may reaſonably be expected to yield fifty Pound an Acre, and ſometimes in favourable Seaſons, when the Soil and Situation are right, an Hundred.

Theſe Things conſidered, nothing is more ſurpriſing than that Hops are not propagated univerſally: at preſent the Planter need not be afraid of over-ſtocking the Market. The Demand is greater by much than the Supply, and we annually import a vaſt Quantity of them from Flanders, though vaſtly inferior to our own. No Country ſo much favours their Growth as England; nor is there any County throughout the Kingdom where they may not be raiſed to this certain and vaſt Profit, and with this perfect Eaſe.

Theſe are the common Rules obſerved in puting the Sets into the Ground; but as this is an Article of the greateſt Conſequence, the whole future Advantage depending upon it, we ſhall enlarge upon the Particulars to be conſidered reſpecting it.

Let the Planter ſee that his Holes are open and perfectly prepared, before the Sets that are to go into them are taken out of the Ground, for the beſt Care that can be taken of them is the clapping them quickly into their Places, nothing prejudicing them ſo much as keeping them long out of the Earth.

In the taking them up the greateſt Caution is to be uſed, not to bruiſe the Roots; and whatſoever Parts of them may happen to be ſo injured, muſt be cut off beyond, that is, above the bruiſed Part, for this always decays; whereas, when the Roots are cut off clean, they not only are ſo many Mouths themſelves, but every one of them ſhoots out ſeveral ſmall Roots; which does not happen if they be cruſhed and injured. Theſe Parts grow preſently mouldy, and the Infection ſpreads from them to the reſt of the Plant: every Fibre that runs near one of theſe mouldy ones is ſure to be tainted. Not only the Fibres are to be cut off at the Ends, and the injured Roots to be cut away, but if there be any Roots that run croſswiſe of one another, or any that ſpread with a Tendency upward, the firſt are to be cut quite off, and the others are to be ſhortened almoſt to the Set. The croſs Roots, if too near, will preſs and injure one another; and the Hop is to root deep in the Ground, therefore the others ſtruggle in a wrong Manner.

As to the Depth of the Holes made for receiving the Plants, what we have given is a general Rule, but it may admit of Exceptions; and we are in this Article to accommodate ourſelves to the Condition of the Ground. If that be rich, free, and fine, we may plant the deeper, but if it have a bad Bottom we muſt go the ſhallower in the firſt ſetting, leaving the Plants to puſh afterwards.

When the Hole is dug and the Plants are ready, let the Planter obſerve that he ſet them ſo, that as near as may be they may ſtand covered juſt as far as the Point or Head; and when the Hole is ſquare, four are to be placed at the Corners; and if one more be added, it muſt be juſt in the Center; if two more, in a Line going acroſs the Middle, and at equal Diſtances from all the other.

When the Sets are in the Hole let the Compoſt that is to fill it up be broke very fine with a Spade, and thrown in a little at a Time; and in this Manner it will fall all round them, and about each Set, leaving no Hollows. When a little is thrown in it is to be ſettled about them with the Hand, and when all is in it is to be gently preſſed with the Feet, but not too hard: the Intent is, that it may every where fall cloſe about them, and yet it is not to cake about their Stems.

Some who plant in Spring, if the Seaſon be dry, water their young Sets, but this is altogether wrong. The Depth at which they are planted is ſuch, that the Earth will always have Dampneſs enough to ſupport them, and it is a Seaſon when there muſt come Rains ſooner or later upon them.

We have recommended the planting at Autumn, and then there is not the leaſt Hazard of wanting Water, nor the leaſt Occaſion for giving it to them; on the contrary, when People over careful of their new Plantations, will be at the Labour and Expence of doing this, they only injure the Plants; for the Wet, eſpecially if it be too much, rots the Roots. We have obſerved that the Root of the Hop is very liable to Accidents, it will grow mouldy if bruiſed, or on any other ſlight Injury, and nothing will contribute more to that Accident than too much Wet, ſo that the over Care often is deſtructive.

There are People who, inſtead of opening the whole Hole, and ſetting in the Plants regularly by Hand, place them in the new made Ground with a ſetting Stick, cloſing the Earth about them as Gardeners do in the common Way of planting Roots, but this is a very ſlight and inconſiderate Method: the Hop Plantation is an Undertaking of great Conſequence, and 'tis worth while always to ſet about it with Care, and all poſſible Advantage of the Ground: the Succeſs of the firſt Year will over-pay any extraordinary or particular Expence on that Head.

When the Planter has thus got all his Sets into the Ground, let him leave them to Nature

for their Growth; and the next Summer let him watch them in their Fruiting, ſome will riſe worſe than others, but at the ſame time he will find ſome better than the common Run; in this Caſe he is to mark the Hills of both Kinds, the worſt to take away, and the better to propagate. For this Purpoſe let him take particular Care of thoſe Hills on which the fine ones grow; and the next Year, when the Time of tying is come, the ſuperfluous Shoots on theſe fine Hills are to be reſerved for laying. When the others are tied up theſe are to be cut off at the Top, and laid all the reſt of their Length, burying them in the Ground; in this Condition they will each ſend up a great Number of ſtrong and healthy Sets, which in the ſucceeding Autumn may be planted out into Places where the Hops were worſe than the common Run; in this Way every Year the Hop Ground will be improving, and by proper Management in Dreſſing, and due Tendence, will exceed that of any other.

CHAP. VI.

Of dreſſing and managing a Hop Ground.

WE have ſhewn how to prepare the Land and plant the Hops; but if we were to ſtop here, the Huſbandman who ſhould be led to plant, and left without farther Inſtructions, would be bound to curſe us for deceiving him; ſo it would really prove, ſhould he be left in the Dark, for the Management of his Plantation. The Profit from the Hop is very certain, though it vary greatly, according to the Seaſons and Accidents; but this certainly ſuppoſes a due Knowledge and Care in the dreſſing of the Ground, for it will be ſix Times as great from a Ground well, as from one ill managed. He is not to look for this Information among the Planters themſelves, for they know very little, and that little they keep very ſecret. Half their Plantations come to little, from want of Care or want of Judgment; and from what I have ſeen I ſhall freely add, that the very beſt of them do not yield half their natural Produce.

There is not any Hop Ground I have ſeen but might double the Owner's Profits, with a more judicious and diligent Management: we ſhall lay down the whole Method, and it will be found not at all difficult or perplexed, only when ſo familiar a Practice is rightly underſtood, let it be carefully followed and obſerved in every Article. Let not any be afraid of the Expence of managing a Hop Ground, for it is really very moderate; nor let him be terrified at the Plantation being liable to Accidents; for though it is more ſo than any other Growth whatſoever, yet with due Care one half of them may be prevented, and the greateſt Miſchief of the other remedied. Of this we ſhall treat at large in a ſucceeding Chapter, not to break in upon the Thread of the Subject here.

The firſt dreſſing of the Hop Ground depends upon two Principles, the Earth is to be broken and divided that the Roots may find an eaſy Paſſage; and the Weeds are to be deſtroyed as they riſe, that they may not rob the Plants of their Nouriſhment. There is no Way of doing this ſo proper as by the Horſehoeing, becauſe that at the ſame Time as it deſtroys the Weeds, breaks the Ground thoroughly between the Hills; and the Hops ſoon ſpread beyond them into the Ground.

The young Plants will now have the Winter for fixing themſelves in the Earth, they will ſhoot out freſh Roots before the Cold reaches the Depths at which they are planted; and theſe will ſtrengthen themſelves well in the Ground before Spring, that they will then ſhoot vigorouſly both in Roots and Tops.

CHAP. VII.

Of polling the Hops.

THE Poles are now to be provided, for the ſooner they are fixed the better, that the Roots may not be diſturbed in their new Shoots by them.

Three, four, or five Poles muſt be allowed for each Hill: the Difference is according to the Diſtance of the Hills; if theſe be at ſeven Foot three Poles will do for each, if at eight Foot four, and if the Ground be very rich, and the Diſtance of the Hills nine Foot, there ſhould be five Poles to each. In general the poorer the Land the nearer the Poles may be placed, for where that is rich, and the Growth is luxuriant, they muſt be at a greater Diſtance.

In the ſame Manner the Bigneſs and Length of the Poles is to be proportioned to the Condition of the Ground, and the Growth of the Hops. In moderate Ground Poles of a moderate Size will do, but in rich Earth, where the Hills are diſtant and the Growth ſtrong, the Poles muſt be large, ſtout, and very tall, otherwiſe a great Part of the Profit may be loſt from this Deficience.

The Growth of the Stem of the Hop will be in a great Meaſure determined by the Length and Bigneſs of the Pole; if that be tall the Stalk will run up, and if the Ground be but poor when this happens, the whole Nouriſhment will be exhauſted on the Stem and Leaves which ſhould go to the Hops, ſo that they will make but a poor Progreſs. This is the Caution neceſſary againſt over-polling the Ground, than which there is no Error more deſtructive. On the contrary, when the Earth is rich and able to ſupport the Plants, and when the Hills are placed at ſuch a Diſtance that there is Space for the Roots wandering for Nouriſhment, and that is provided in Abundance by the dreſſing of the Ground between, in that Caſe we can get no Poles too long; for there are none ſo high but the Stem of the Hop can get to their Top, and flouriſh over it, and yet have Strength at the Root for nouriſhing and filling the Fruit, which will be the more numerous in proportion as the Plant is larger and ſpreads more.

We are now ſpeaking particularly of the firſt Year of a Hop Ground, and in this ſome particular Caution is neceſſary. If the Ground be but indifferent, let the Poles be very ſhort this firſt

Year, for nothing is ſo dangerous as the carrying up the Plants too much in Height the firſt Seaſon in ſuch Ground: where they have no Abundance of Nouriſhment, and have not been able ſince their planting to ſearch thoroughly for what there is. If they be led into a Habit of running too much into Stem this firſt Year, the Fruit will be ſmall, and perhaps the Fault may never be recovered.

Even in the beſt Grounds where ſoon after no Poles can be too long, it is a very good Caution to uſe ſuch as are ſhorter the firſt Year, not tempting the Plants to run up too high, but encouraging them into Fruit. They will be ready enough to take the Advantage of the longeſt Poles afterwards, and fill the whole Length with Fruit.

An Acre of Hop Ground will require between three and four thouſand Poles. Let theſe be got ready, and early in Spring laid in upon the Ground between the Hills, to be in readineſs. Fifteen Foot is a moderate Length. The largeſt Poles which are fit for the richeſt Ground and beſt Hops, ſhould be twenty Foot long, and ſeven Inches round, but theſe are too large for any Ground or any Condition of the Hops the firſt Year; ſo that ſomewhat ſmaller are better in all Kinds in the Beginning.

Alder Poles are very proper, they are ſtrait and run high; Aſh alſo are excellent, becauſe of their Toughneſs, and there are ſome other Woods that do well enough. They ſhould be cut with a Fork at the Top, for it ſerves to give a Support to the Head of the Plant, and is of the greateſt Service.

The Time of polling is one of thoſe Circumſtances that require the greateſt Care in the Management of a Hop Ground, it muſt not be done before the Shoots appear above Ground, becauſe the Plants may be injured by it, and the proper Place cannot be known; and on the other hand, if it be deferred long after they have ſhot, the Plants will be checked, for the Hop ſtops preſently in its free Shoot, if it have not a Support to climb upon. This Work is to be begun after the Shoots appear, and muſt be finiſhed before they are any where three Foot high, and this in a large Ground is a ſharp Buſineſs, for the Hop grows very quick in its firſt Shoot. The Poles are to be fixed near each Hill, three, four, or five to each, according to the Rule before laid down, and they are to be fixed in Depth according to their Height, and to the Condition and Expoſure of the Ground. The richer the Ground the deeper they muſt go, and the more they are expoſed the firmer they muſt be placed; indeed we have obſerved that a Hop Ground never is to be in an expoſed Situation, ſo that the Danger there ought not to be great.

Let the Planter conſider that nothing is ſo deſtructive as the riſing of a Pole out of the Ground: the breaking of one, though a troubleſome Accident, is not near ſo bad, on this Principle let him work, fixing them in the Grounds ſo firm, that if ſuch Violence is offered they will ſooner break than riſe.

There is a great deal in the fixing them, not only in Point of Strength but Poſition, they muſt always be placed ſo as to lean a little outward, though not much. It is natural to plant them a little ſlanting inwards, and ever ſo little of this is wrong. The Hop, more than any Plant whatſoever, requires a free Air to paſs all round it, and this is prevented by the Poles bending inwards. Moſt of thoſe Diſorders of Hops, which are ſo injurious to the Planter as we have ſhewn before, ariſe from the Want of a free Paſſage of Air, this we ſhall explain at large in its Place. The naming it here may be ſufficient to give the Planter a Caution not to let his Poles ſlant inward; if this be ever ſo little, the Weight of the Hops will ſoon make it more, and they will cloſe in at the Top like a Canopy over the Hill, the Conſequence of this is a certain Taint in the Hops.

To prevent this it is that we order the Poles to be fixed ſlanting a little outwards; but let Moderation govern here, if they ſlant too much the Weight of the Hop will lean them down the other Way, which is alſo wrong. The Buſineſs is to keep them as upright as poſſible. Therefore let the Planter obſerve how the Tops of the Poles ſtand when he has fixed them; if they are a very little more diſtant at the Top than at the Bottom they are right, not otherwiſe.

Another Caution is, that they are made to lean a little toward the South. This is very eſſential, for it gives the Sun Opportunity to ſhine in among them; which is of the utmoſt Conſequence. Hops perſpire a great deal, and that damp Vapour is apt to hang amongſt them. This taints them, and is the Origin of many of their Diſorders. The Sun ſhining freely in at the ſame Time, diſpels this and warms the Plants, it keeps them from Damage, and aſſiſts the Growth and ripening of the Fruit. This leaning however muſt be but moderate, as the other, for if great it prevents the very Intent wherewith it is done, for the Plants will obſcure one another, and the Sun cannot get in.

We have obſerved at firſt, that great Care is needful in the Management of a Hop Ground, it will be ſeen in this Article the ſtricteſt Nicety is required in this Inclination of the Poles. It is confirmed by repeated Experience, that a Pole which leans a little will bear one third more Hops, than one under all the ſame Advantages in other Reſpects, that ſtands upright: but of this I can aſſure the Planter, from my own Experience alſo, that a Pole which leans too much will yield fewer Hops by one third than one which ſtands perpendicular: and beſide the Defect in its own bearing, will hinder that of others.

There is alſo another very ſubſtantial Reaſon againſt the too great leaning of an Hop Pole, that is, the Danger of its breaking, which is a bad Accident, or of its tearing up, which is a ſtill worſe, when the Weight of the Hop bears upon it.

CHAP.

CHAP. VIII.

Of inſpecting the polling.

AN Accident in the polling of Hops, if a careful Eye be kept over them, and it be ſeen in Time, is eaſily remedied; and there ought to be ſuch an Eye continually upon the Ground, to inſure the full Profits.

Firſt, if upon the ſhooting of the Hop at ſix or ſeven Foot high, it be ſeen to be over-polled, that is, if the Pole be ſo tall that it will be apt to carry it up in Length, and prevent its fruiting well, it may be unwound from the Pole, that may be taken up, and another may be ſet in its Place, and the Hop brought carefully round it, and it will take to it as naturally as to the firſt. In the ſame Manner if it be ſeen, from the free growing and promiſing Aſpect of a Plant, that it is under-polled, or that it will bear a taller and ſtouter, it may be unwound, and ſuch a one ſet in the Place of the other.

In the ſecond Place let the Planter go through his Ground, and inſpect carefully the Condition of all his Poles, as to their Firmneſs in the Earth; let him be particularly careful in this Reſpect, in Places where the Wind has moſt Power. When he ſees any in Danger let him order a Man with a Rammer to force down the Mould, on the Side of the Pole oppoſite to the Wind, which will enable it to reſiſt the Efforts.

Thirdly, let him take Care to have ſpare Poles of different Sizes, not only for the replacing ſuch as are too ſmall or too large for their Plants, but for the ſupplying the Place of ſuch as ſhall break, for this is an Accident that will happen; and it muſt ſpeedily be remedied. A Hop Plant that is ſuffered to lie upon the Ground, will yield very little.

Fourthly, let him be ready not only to remedy ſuch Accidents, but to prevent them. He will ſee where a Pole is over-burthened and in Danger of breaking, and let him not ſtay for the Accident, but place in a ſpare Pole to ſupport the other.

And finally, where he has not perceived in Time, that a Hop was under-polled, but ſees it requires a taller Pole, when it is too late to unwind it, let him place a ſquare Pole near the other, and trim the Hop to it, that it may have a freſh Support, and Room to ſpread to the greateſt Advantage.

CHAP. IX.

Of the tying of Hops.

THE Huſbandman who ſhall have a Deſign of entering on the Hop Branch, though ever ſo unacquainted with it before, and ever ſo much out of the Way of Inſtruction from thoſe who practiſe it, will find here ſufficient Directions under every Article; and provided he will obſerve carefully the ſeveral Directions, and keep a conſtant Eye upon his Ground, we will venture to aſſure him of Succeſs.

He has ſeen how he is to prepare his Ground, plant his Sets, and fix his Poles. The next Article is the fixing the Plants to theſe Poles, this is done by tying.

According to our Directions of not ſetting in the Poles till the firſt Shoots appear, it will be time to begin tying by that Time they are all well in the Ground. For the proper Time to begin to lead the Plant is at about a Yard high.

Let the Ground be now carefully looked over, let it be conſidered what each Pole may bear, and ſo the Plants proportioned to them. This done let each Shoot be led to the proper Pole, which is uſually the neareſt, and let it be wound once or twice about it, in a Direction according to the Courſe of the Sun, for the Heat naturally draws the Shoot that Way, and the Courſe of Nature is not to be perverted.

When it is thus fixed to the Pole it is to be tied round, to keep it there. Any ſoft Matter does for this Purpoſe, a Piece of Baſs or withered Ruſh, or a Fragment of Yarn. Care muſt be taken that the Stalks of the Hop be not hurt in the tying. Let them be tied in two or three Places, but let a great deal of Caution be uſed in doing it, that they are not preſs'd, for the young Shoots are tender, and the damaging of them will be of very bad Conſequence. The Heat of the Day is the beſt Time for the doing this, for in the Morning, being full of Juice, they are brittle: The Heat of the Sun evaporates ſome of it, and they are then more firm or will better bear a Touch.

After this there muſt be no more tying, but the Plants will ſtill require a great deal of guiding, to keep them properly to the Poles. We ſhall be now advanced to the ſecond Stage of Growth, and our Hops which have been tied ſome little Time, will continue ſhooting very quick; and in general, if they have been carefully wound and tied, they will follow the Courſe intended round the Pole, very freely and favourably. But there will have been leſs Care taken of ſome, for no Work is ever done throughout with perfect Regularity, and there will be ſome Plants very luxuriant and very croſs-grained, that will ramble from their Poles, and hang wild and drooping; theſe muſt be ſet right with the Hand, for the firſt Week or ten Days: toward the End of APRIL the Planter muſt himſelf go over his whole Ground again, and ſee what farther is amiſs in the ſame Way: ſomething will ſtill be amiſs; and no Hand is ſo fit to rectify it as his own. No one's Intereſt is ſo much concerned, and therefore no one will be ſo careful; the Tops which ſtraggle from their Poles, will now be above the Reach of his Hand; he muſt therefore take a forked Stick, of five or ſix Foot long, and with this he muſt turn and direct them properly to the Poles, which they will readily enough take to when once put round, though they had ſtraggled naturally ever ſo much from them.

A Fortnight after this, that is, toward the Middle of MAY let him go round once again, with the ſame Deſign. His Workmen muſt have

have general Orders to rectify what is casually amiss, from Day to Day; but these are the Periods whereat he should go through the whole himself; and they return so quick, that if it be a considerable Ground they will allow him little Respite. When we advise this compleat Attendance to be given by himself, we suppose the Ground to be but of a moderate Extent, and the Planter not very much pressed by other Affairs. When the Ground is larger, and the Owner has Affairs that will not permit himself to attend, he must depute some careful and faithful Person; and still follow at Times with his Eye, what he does not execute with his Hand.

At this Inspection in May, whether by himself or a Servant, the greatest Care of all is required for two Reasons; first, because it will be the last Time of going over the Ground; and secondly, because Faults at this Time are of worse Consequence than at any other.

On this last View he will find several that have straggled from their Poles, or that grow crosly since his last reducing of them. They are very strong at this Season, and the least Fault encreases to a very great one presently, therefore let him go over them now with redoubled Care. Neither his Hand nor the Stick will now reach them, for they are by this Time grown to a very considerable Height; whoever does the Business must be followed by a Labourer with a Ladder, with a Back to it, and this must be set down against every Pole where there is any thing amiss: every Fault is to be thoroughly rectified, and they are then to be left to themselves for a Month.

CHAP. X.

Of clearing the Ground and raising the Hills.

THIS is a very considerable Article in the Care of a Hop Ground, which too many practise too slightly, and which the best Managers I have seen do not go through with sufficient Diligence and Attention; let the Husbandman who plants upon our Plan regard it more perfectly.

We left the Hops in the last Chapter at a good Growth, toward the latter End of May, directed rightly in their Course along the Poles, and prepared for a beneficial Crop. We are now to proceed to the next Operation, which is that of shortening the Plants, but as it is a Month before that is to be performed, it will be proper to consider the Condition of the Ground, and the Work that is to be done in the mean Time below.

We have said the Earth is to be stirred from time to time between the Hills, and the Weeds are to be destroyed as they rise; this is a general Direction, but we are to come to Particulars in this Place. We have frequently spoken of the Hills in the Hop Ground, but that Name is given to them in Consideration of what they are to be, rather than what they are in so young a State of the Plantation as that we have hitherto described; they as yet rise only two or three Inches above the Level of the rest, and are only of a small Diameter. We see them larger in old Grounds, and we are about to enlarge them in our new one.

Holes were dug for the planting the Hops, these were filled with Compost for the Reception of their Roots, four of the Sets were planted at the four Corners of each Hole, and the Earth was raised two Inches very lightly over their Tops, which were on a Level with the Surface; therefore the Spots where they now stand are a little raised, and the level Ground between is plain, as the Harrow left it.

In this Condition we see it in the Beginning of June, and we then are to begin to give it more the Form and Appearance of a Hop Ground. After the first Shower let a Number of Labourers be sent into the Ground, with an Overseer of the Work; he is to set them to pare off the Surface of the Earth between the Hills, about two Inches deep, himself is in the mean Time to be at work at the Hills. He is with a careful Hand to cut away all the superfluous Shoots of Hops, and thoroughly to destroy all the Weeds that rise upon the Hills; this Earth which the Labourers pare from the Surface, is then to be shovelled to the adjoining Hills, and carefully laid upon them. In this Manner they will be encreased both in Height and Breadth, and the Ground will have more Appearance of what it really is.

We mention the Spade for this Purpose, because it will suit a moderately large Ground. In a very small one the Handhoe will do; and in a larger the Horsehoe, or Hoe Plow, invented for the Service of the new Husbandry, is best of all. It is much the best Method to set out with a large Piece of Ground at once, and to prepare it for this Instrument by the Disposition of the Hills as we have directed; there is no Article in which it is more largely serviceable; nor will any Hop Ground succeed so well nearly, as one that is so managed.

Whichever Method be taken, whether that by the Spade, Handhoe, or Hoe Plow, it is to be conducted in the same Manner, the Hills are to be raised, with the Earth thrown up, and the Weeds destroyed.

This is to be repeated once in three Weeks, during the whole Summer, exactly in the same Manner, always taking the Advantage of some Rains, for the Earth cuts better, and every thing is more compleatly done at such a Season. This perfectly kills all Weeds, and the Earth added from time to time, keeps the Hills moist, and gives Nourishment to such new Roots as shoot from the upper Part of the Set.

CHAP. XI.

Of shortening the Hop Plant.

THIS is a Practice much more essential to the Success of the Plantation than many imagine. It depends upon the plain and certain Principle in Vegetation, that in order to promote a Plant's bearing a great Quantity of Fruit,

it

it is not to be ſuffered to ſpread too much out into Leaves, or to riſe too much in Height.

We left our Hops at the End of May conducted properly along their Poles, and in a Way to take the ſucceeding Part of their Growth to the beſt Advantage.

In this Condition they are to be left to Nature for a full Month, they will be growing in Length all that Time, but at the Period of it they ſhould begin to branch. Many of them will do ſo naturally, but ſuch as do not, muſt be put into the Way of it by Art, and this is to be done by ſhortening the Stalk; that is, by taking off the Top Shoot.

Some prevent the ſhooting farther of the Stem in Length at this Time by turning it from the Pole, and this ſometimes anſwers very well, but it is not ſo certain or ſo ſpeedy a Way as the other.

According to the Directions we have laid down already for the proportioning the Poles to the Plants, we have given a Rule nearly how far in Length each Plant may commodiouſly be allowed to riſe. The Ladder with its Stay is now to be brought into the Ground again, and ſet againſt every Hill; ſuch Plants as have begun to ſpread, are to be left to Nature; for the Branches which are ſhooting out from them will draw the Nouriſhment, and there will not be any abundant Quantity ſent into the Top Shoot. But where it is ſeen that Nature puſhes all her Store this Way, and there is no Appearance of Branches, the Bud or Top of the Shoot is to be pinched off; and this ſtopping its Progreſs that Way, will give all the Sap to new Shoots and Branches. The more of theſe the better; and as they ſeldom grow much till toward the End of June, they are then prevented from being luxuriant by the great Quantity of Sap that is devoted to the Nouriſhment of the Fruit.

This is a very happy Proviſion of Nature in favour of the Planter, but he muſt favour it, and purſue the ſame Courſe; otherwiſe Accidents will interfere and prevent much of the Advantage. Nature ordains that about Midſummer, the Hop Plant ſhall ceaſe ſhooting at length, and begin to branch; and if a rainy Seaſon, or any other Accident tend to interrupt her Courſe, and continue its Growth in length, he is to ſtop it by pinching off the Bud. In the ſame Manner Nature intends that theſe Branches ſhall grow but to a moderate Length, and then fill themſelves with Fruit; but ſometimes a luxuriant Soil, or a croſs Accident of one Kind or other, will prevent this Purpoſe by the ſhooting of theſe Branches into too great a Length. In this Caſe the Planter is to treat them juſt as the main Plant. He is to nip off their end Buds; and as the Seaſon is by this Time far advanced toward the fruiting, Nature will now follow her own Courſe, and turn all her Treaſures thither.

A Plant that would have run thus into a uſeleſs Stem, or when there were Branches formed, would have extended them to a great Length, at the Expence of what was to be of Value, will by this prudent Management be thrown into a proper Courſe, its Stem ſhortened, and the Branches ſtopped in their Growth till every Part be full of Buds for Fruit: this is its full Perfection.

The Planter is now only to obſerve their ripening, in this he is to wait the Courſe of Nature, he can do nothing to aſſiſt her, and he is only to watch that he may take the moſt favourable Opportunity for gathering thoſe Fruits, the free Growth of which he has promoted by his Induſtry and Care.

CHAP. XII.

Of the gathering of Hops.

IT is not without Reaſon we have ſaid, the Planter is to watch his Opportunity of gathering Hops when they are ripe. Care and Attention has been directed throughout every Step of his Buſineſs, and there is no Part in which it can be omitted without Loſs, but there is none wherein the Damage of the ſmalleſt Neglect will be ſo great as here.

The Hops begin to flower about the laſt Week in July: in a Fortnight after the firſt Appearance of the Flower, the Fruit begins to form itſelf for Perfection. This is, in the Phraſe of the Planters, called the belling of the Hop, and it is to be expected in the Beginning of August: from this Time three Weeks, in a good Seaſon, compleatly ripens them. So that the Planter may expect them in condition to gather in very favourable Seaſons, in the End of August; in middling Times, in the Beginning of September; and in the worſt, ſoon after the Middle of that Month.

It is needful the Owner watch carefully for this ripening, let him begin the laſt Week in August to examine them daily, and ſo continue till he find them ripe.

The Marks of their Ripeneſs are theſe. Firſt they change Colour, this is a ſure Token that their Maturity is coming on: after this they begin to ſmell fragrant and ſweet; in a few Days after the Seeds upon Examination will be found turned brown; and ſoon after this the Hop will eaſily fall to Pieces.

Theſe are the four Stages of the Hops ripening; in the firſt and ſecond that Period is comeing on; in the third, it is perfect; that is, when the Hop has changed Colour, the Smell is ſtrong, and the Seeds are brown, it is perfectly ripe; in the fourth Stage it is beginning to fade, for this is the Courſe of Nature: when Things have attained Perfection, the next Step is Decay.

The Progreſs from Perfection to Decay in the Hop is very quick, 'tis therefore we have recommended ſo particular and watchful a Care over it at this Seaſon. When the Owner perceives them to have all the Signs of Ripeneſs, let him get together all the Hands he can for a quick gathering. One Day hanging upon the Plant after they are fully ripe hurts them, and if there ſhould happen a windy Night, as is not uncommon at that Seaſon, he may receive vaſt Damage.

There are too many who gather their Hops irregularly, and by that ſuffer a great deal of

Loſs. The moſt uſual Manner of doing it is this. Begin in the Centre of the Ground: Cut down four Hills that ſtand together, cut the Roots even with the Ground, then lay the four Hills, and the Ground that is between them all level, in the Manner of a Floor: water this, beat it with a Mall, ſuch as they uſe in Turfing, then ſweep it and roll it with a heavy Roller.

This will be a fine level Floor, and is to be the Place on which to pick the Hops. To this Place they are to be brought from all Parts of the Ground, if it be a ſmall one, all being at equal Diſtance from it; but in very large Grounds, another or ſeveral others according to the Extent, are to be made in different Places, but always central to ſome large Quantity of the Ground, for the Convenience of bringing the Hops from every Part to it.

The Hops to be picked are laid on this Floor, and the Pickers are to ſit all round it, and to pick them into Baſkets; the Floor is to be cleaned and ſwept once in three or four Hours, and this Way the Work is continued till all is finiſhed.

The Method in which the Hops are to be taken up is this. Firſt, let the Perſon employed in this Article, go round thoſe he is about to raiſe, with a long Pole in his Hand, with a ſharp Hook at the End of it: let him obſerve where the Tops of thoſe Poles he is about to take up, grow entangled with others, and with this Hook let him cut all theſe gently aſunder. Every Thing is to be done with Care and Caution in the gathering of Hops, and if this ſhould be omitted, the Stalks would pull one another, and ſhake off the Fruit in the removing. When the Plants of the ſeveral Poles he is about to remove are thus cleared, he is to cut them off at the Bottom.

It is a common Cuſtom to cut them near the Ground, but this is a very great Error. The Hop is in a Condition of great Strength at this Seaſon, vaſt Quantities of Sap have riſen for the filling of the Fruit, and they continue riſing ſtill; ſo that in cutting the Plant off near the Ground, a Wound is made that does not eaſily heal, and that bleeds a great deal to the weakening of the Root.

The proper Method is to cut them off at a Yard from the Root, and they muſt be taken up only as they are wanted, proportioning the Quantity taken up at a Time to the Number of Perſons employed in picking.

As many Plants ſhould be cut off at once as will find them Employment a Quarter of a Day, 'tis hazardous to venture cutting up any more, for either a hot Sun, or a Shower of Rain will do a great deal of Harm to thoſe which are cut.

When the Plants are looſened from their Intanglings at Top, and cut off at Bottom, all is not done. They are not to be unwound from the Poles, for they twiſt themſelves too cloſely, and too irregularly about them for that; the Poles are to be taken up, and the Hops picked off as the Plants are on them.

The Method is to raiſe them out of the Ground. Some do this by Hand, rocking them about, and then pulling them up; but we have adviſed them to be too well faſtened for that. Poles thus eaſily taken up, are but in a bad State to ſecure them againſt the Wind.

The Planter ſhould have a large Pair of Knippers, or ſome other Contrivance for this Purpoſe, and a Block of Wood to lay near the Pole, that while the opening of the Knippers takes hold, their Handles may have the Effect of a Lever. Theſe Knippers may be of Wood or Iron, the latter is more expenſive, but vaſtly the better. Theſe ſhould be made with very long and ſtrong Handles, and ſhould open like a Smith's Tongs, but be well toothed on the Inſide.

When they are to be uſed it is thus. Firſt rock the Pole about with the Hand; then lay the Block of Wood near it: then the Points of the Knippers are to be thruſt into the Ground open, to take in the Pole, and the Handles to reſt upon the Block. When they are cloſed, and have good hold, the Pole is to be raiſed out of the Ground by bearing againſt the Block.

The wooden Inſtrument for this Purpoſe muſt be a large, long, and ſtrong Lever, ſplit and kept open at the End. There muſt be Iron Teeth in this open Part, and it is to be uſed exactly as in the former Direction.

We have obſerved that the Hop Poles ſhould have a Fork at the End for the better keeping the Top of the Plant, but for the common Way of picking upon the Floor, it is beſt they ſhould not, becauſe they come the eaſier off when the End is ſingle.

In the picking of Hops great Care muſt be taken that it be done clean, if there be any Fragments of Stalks left among them they diminiſh their Value. The little theſe Foulneſſes add to the Weight, is of no Conſideration compared with the Reduction they occaſion in the Price.

We have given very punctual Directions for judging of the Ripeneſs of the Hop, as that is an Article of great Conſideration; but we are not to omit obſerving that there is a Diſpute among the Planters at what exact Degree of Ripeneſs it is moſt profitable to gather them.

We ſhall give the Facts as they appear upon Trial, for there is no other Way of judging. When the Hops are but moderately ripe, they are of a better Colour, and they preſerve it when dry, and at the ſame Time they are ſure to retain all their Seeds, in which their greateſt Virtue lies: this has led many away at once to the reſolving to gather them in this State. The Advantages are very certain, and very apparent; but let us examine the other Side of the Queſtion.

It is true that the Hop does not dry to ſo fine a Colour when very full ripe, and that it naturally drops ſome of the Seeds; but on the other Hand, the full ripe Hop has its full Subſtance, which the other has not: and as it is leſs watery, it does not loſe ſo much Weight in drying. Five Pounds of moderately ripe Hops yield a Pound dry, and four Pound of full ripe ones do the ſame. Therefore tho' the others bring a large Price at Market, yet unleſs it be larger by that Difference, the Advantage will be

be in letting the Hop ſtand to its full Ripeneſs.

This is the exact Fact on either Side, we have no more to do than to propoſe it: the Planter may now take his Choice of the two Methods.

CHAP. XIII.

Of the drying of Hops.

WE have led the young Planter through the whole Courſe of his Undertaking in a Hop Ground: from the preparing the Land, to gathering the Fruits of his Labour. His Hops are picked and he is to dry them. This is to be done by a Kiln erected for that Purpoſe, but we are to caution him in the firſt Place to be very quick in doing it. No Time is to be loſt in the picking after the Hops are cut up; and when they are picked no Time is to be loſt in drying them. Their lying but a little while together after they are picked heats them, and the firſt Effect of this is the Loſs of their Colour, the next is the Loſs of their Smell. Few let them lie long enough to incur the laſt Damage, but the former is too frequent, and it is not to be remedied.

It may happen that the Kiln is full when a great many are picked and ready for drying. This is to be avoided as carefully as poſſible, by proportioning one Part of the Work to another; but if it happen unavoidably, the Method is to ſpread them very thin upon the Floor of ſome covered Place where there is a thorough Air, that what drying they thus get naturally may be regular.

A ſmall Quantity of Hops will dry compleatly thus; and a larger will get no Damage in lying a Day or two; and it muſt be very bad Management indeed if the Kiln is not by that Time ready for them.

Nothing is ſo eaſily damaged as the Hop in drying: and all the Care beſtowed in the raiſing of it is thus rendered ineffectual; for the Price is reduced at Market, and the Value alſo for Home Conſumption; the Merit of the Hop is its perfect Fragrance and fine Colour, and theſe can never be preſerved but by the moſt careful Manner of curing.

Let the Planter be cautious not only that his Hops be dried well, but that they be all dried alike; and if it happen that one Parcel differ from the reſt, in this Reſpect let him keep them ſeparate; for one Pound of ill dried Hops, mixed with fifty of the beſt preſerved that can be, will deſtroy the true and rich Smell of the whole.

Having delivered the Cautions in this Reſpect, we ſhall now lay down the Manner of doing it.

It is a common Practice in ſome of our Hop Countries, to dry them in a Malt Kiln, upon a Hair Cloth ſtretched out for that Service. In FLANDERS they build a Kind of Kiln on Purpoſe; and in ſome other Places they alter the Malt Kiln for this Uſe: we ſhall give the Planter his Choice of theſe ſeveral Ways, but not without pointing out to him which deſerves the Preference.

CHAP. XIV.

The FLEMISH *Manner of drying Hops.*

THE Method uſed by theſe Planters is to build a Kiln of Brick; which is a Room of about ten Foot wide: the Door of this Room is made on one Side, and the Fire Place is in the Center, and for a Room of ten Foot, it is fifteen Inches wide in the Clear, and ſo many deep, and its Length muſt be within five Foot that of the Room; it is to run all along the Middle, and to terminate two Foot and a half from each End, that the Perſon who has the Care of the Work may go round it: or it may be free only at one End for a Paſſage, and be made in the Manner of the Fire Place of our common Malt Kilns, the Fire paſſing out at Holes on each Side.

This Fire Place muſt be made on the Floor: and four Foot above the Top of it is to be made the Bed, whereon the Hops are to lie. This muſt have a Wall of three or four Foot high round about it, to keep them from falling off.

Adjoining to the Kiln there muſt be a Room into which the Hops are to be put when dry; and a Window is to open out of the Place where the Bed is, into this Room, that they may be ſhovelled through without Trouble.

The beſt Floor for the Bed is made of a Kind of Rails like our Pantile Laths, they are to be an Inch ſquare, perfectly well planed, and they are to be placed a Quarter of an Inch aſunder, that the Heat may freely paſs through, and the ſmalleſt Hop not fall out. There generally runs a Beam croſs the Bed in the Middle, and the Rails are all let into that even with its Top.

When this Kiln is prepared the Hops are to be thrown in as they are picked, one Baſketful after another, till the whole Bed is full, and they lie a Foot and half deep upon it. They muſt be let to lie as they fall, and not preſſed down any Way: it will be proper to draw a wooden Rake over the Surface, that they may not lie thicker in one Place than another; but this muſt be done lightly.

When the Hops are in and thus ſtroaked even, the Fire is to be kindled. In FLANDERS they burn dry Wood, and that often but of an indifferent Kind; but it is much more proper to uſe Charcoal, which we would adviſe the Planter to burn himſelf, with a particular Care, for that Purpoſe.

The FLEMISH Hops are commonly cenſured for having an ill Smell; and this is owing entirely to the Practice of burning Wood under them. Let the clean Fuel we have directed be uſed, and that Fault will be perfectly avoided.

The Fire muſt be a pretty good one, but it is not to be continued all along the Fire Place, it muſt be only at the Mouth of the Furnace; for being well kept up there, the Air which paſſes through will convey the Heat to every Part of the Kiln.

This Fire is to be continued till they are thoroughly

roughly dry, but this muſt be carefully regarded, for they ſometimes do not dry equally.

The Way to try whether they are dry enough is to examine them at Top; if they are thoroughly dry there they will rattle on drawing a Stick over them; and if they are thus dry in ſome Places, and leſs in others, they muſt be thinned where they are dampeſt, throwing what are taken off upon the dryeſt Places: thus the Fire being continued they will ſoon be all finiſhed.

This is the only ſtirring the Hops are to have when dried thus: but the great Care is to keep an equal Quantity of Fire all the Time, that there may be throughout an even Heat. When they all appear to be thoroughly dry by their Colour, Aſpect, and Rattling, they are to be tried by breaking the inner Stalk, if that ſnap freely they are dry as they ſhould be; and this is a certain Rule, for till they are that Stalk never is rightly brittle.

If they are not found to be perfectly cured, the Fire is to be continued a little longer: if they be finiſhed it is to be let out, and the Hops are to be ſhovelled out at the Window, into the Room prepared for receiving them. After this the Floor of the Kiln below is to be ſwept, and what Seeds and broken Hops have fall through the Railing, muſt be got together and put to the reſt. Then a freſh Quantity of Hops are to be put in, the Fire is to be lighted, and the whole Procedure is to be repeated exactly in the ſame Manner as before.

CHAP. XV.

The Way of drying Hops in a Malt Kiln.

THIS is a Method of drying them, which comes much eaſier than the other, where there is a Malt Kiln in readineſs, becauſe the Fire Place there is made to ſerve, and the Trouble and Expence of a particular Building is ſaved.

We ſhall not, in this Place, deſcribe the Structure of a common Malt Kiln, that is ſufficiently known; and we ſhall alſo have Occaſion to ſpeak of it particularly hereafter in its Place. The Manner of employing it for the drying of Hops is this: a Hair Cloth is to be uſed as a Bed for the Hops, and they are to be ſpread upon it ſix Inches thick.

They are thus kept over the Fire made in the uſual Way, till they are about half dry; then they are turned with a Scoop made for that Purpoſe, the lower Part upwards, and the upper Part, which was leaſt done, loweſt; thus they are to lie till the whole Quantity is thoroughly dried.

When they are done the Hair Cloth is removed, and they are thrown into a Room; where they lie ready for bagging. This is the Method of drying Hops at the Malt Kiln; in Favour of which nothing can be ſaid, but that for ſmall Quantities, where there is a Malt Kiln near, it may be convenient to ſave the Expence of a Building erected on Purpoſe.

The Hop Branch however is ſo profitable, that we ſhall adviſe the Farmer to ſet out in it boldly, taking a large Ground, and not ſparing the firſt Expence in any needful Preparations. So that this Expedient will be of little Service to him, wherefore we have treated of it more ſhortly.

For thoſe who find it proper, according to their particular Occaſions, this Caution is to be given them, that they take great Care in the turning, to do it gently; and that they uſe clean Fuel; and keep the Heat uniform and equal during the whole Time.

CHAP. XVI.

Of drying Hops in a Malt Kiln fitted to the Purpoſe.

WE have ſhewn the univerſal Flemish Way of drying Hops; and that Method of doing it in England by the Malt Kiln and Hair Cloth; both are uſed, and may anſwer, but we are here about to propoſe a better Method, which is by preparing a Malt Kiln for that Purpoſe: and before we enter on its Advantages it may be proper to ſhew the Inconveniences of the others.

As to the Flemish Way the Fire muſt be continued longer than in any other, becauſe there is ſo large a Body of Hops to dry; and as they are never turned, the under ones muſt be more done than the upper, and muſt be over-done in the drying the upper ones ſufficiently: therefore there is more Time, more Charge in watching, and more Fuel than need be; and the greater Part of the Hops are too much dried, by which they loſe both Weight and Colour, ſo that they are doubly the worſe, while the Expence is greater.

In the Way by the Malt Kiln and Hair Cloth, the Neceſſity of turning is a great Trouble and Inconvenience, for many of the Hops are ſhattered and broken, to which not only the Motion of turning, but the Roughneſs of the Hair Cloth contributes; and a great deal of the Seed is ſcattered and loſt by the Motion. Perhaps theſe are leſs Inconveniences than thoſe in the Flemish Way, but they are very great ones notwithſtanding. We have ſaid before, that a great deal of the Virtue of the Hop is in the Seed, therefore this is a great Damage; and the breaking the Hop always injures the Price at Market.

We ſee the Inconveniences of theſe ſeveral Methods, therefore let us conſider whether they cannot be guarded againſt; and whether a Way of drying may not be found, which ſhall have all the Advantages attending this Method, without the Damage of either.

This is what we ſhall attempt in the Method which we are about to recommend: it has been practiſed in ſome Places many Years, and the Advantages of it are ſo great that 'tis pity it ſhould not be univerſal. To this Purpoſe let there be a Kiln, the lower Part of which ſhall be, in all Reſpects, the ſame with that of a common Malt Kiln; therefore a common Malt Kiln may be uſed for this Purpoſe, with the following Additions, or there may be one purpoſely erected in the ſame Manner.

When the Kiln is thus far prepared, the Bed for the Hops is to be thus made. Frame toge-

ther

ther a Quantity of Slips of Deal well planed, let them be three Inches broad, one Inch thick, and of ſuch Length as ſuits the Kiln, and the Quantity. Let theſe be laid Checkerwiſe one over another, at four Inches diſtance; let thoſe which lie uppermoſt be let into the lower, and the whole Surface kept ſmooth and perfectly even. This Frame muſt be ſupported by Joiſts ſet Edgewiſe, and ſo placed as to lie in a true Level.

Then prepare a Covering for it, of that ſtrong Kind of Tin called double Tin; let the Meaſure be carefully taken, and the Plates of Tin well ſoldered together, and let the laying of the ſeveral Plates be ſo contrived, that the Joints fall upon the Middle of the Ledges.

When the Frame is well tinned let there be four Sides of Boards made to it. Three of theſe are to be fixed, but the fourth muſt have Hinges: it is to be hooked up in the Time of uſing; but when the Hops are dried and are to be removed, it is to be let down, ſo that they can be puſhed gently off without breaking.

When the Bed is finiſhed let there be a Cover prepared for it. This muſt be exactly of the ſame Length and Breadth, it muſt be made of Boards, and framed together; the lighter the better, ſo it will be able to ſupport its Extent. The Face of this muſt be covered with Tin Plates, laid on evenly, which will be very eaſy, the Boards being planed.

This Cover is to be hung flat from the Roof of the Kiln, at a conſiderable Height above the Bed, but ſo contrived that it may be let lower upon Occaſion, in the Time when it is wanted. The Bed being thus prepared, and its Cover hung over it, Conveyances for the Smoak muſt be made at the Sides and Corners of the Kiln, and then the whole is ready.

Some Expence there is in fitting up this Kind of Kiln at firſt, but it very richly anſwers. Leſs Time and leſs Fire are required, and almoſt any Kind of Fuel will ſerve.

We have obſerved that in the Flemish Way there is a great Error, in uſing raw Wood or any other foul Fuel, but in this Method that Caution is not neceſſary. Then the Smoak or Vapour of the Fuel lodges among the Hops as they are drying, becauſe the Bottom of the Bed is open; but here, as that is covered with Tin, the Vapour never gets among the Hops at all.

We have ſhewn the Conſtruction of this Kiln, we ſhall now proceed to the Manner of uſing it. We ſuppoſe a Parcel of Hops picked and ready for drying, let them be carefully emptied into this Bed by Baſketfuls, and ſpread a little about by the gentle Motion of a Stick, in the Hand of a Perſon who can go along the Sides of the Bed, and from one Part or other reach over it; the Hops are thus to be ſpread about till the Bottom of the Bed is covered eight Inches deep with them pretty evenly; this done the Fire is to be lighted and kept up equally, till the lower Part are dry, and the greateſt Quantity of the Moiſture is evaporated from the whole.

Then let the Cover be gently let down till it comes within ten Inches of the Surface of the Hops, the Fire being all this Time continued as at firſt; the Effect of this Cover will be like the Dome of a reverberatory Furnace, it will reflect back the Heat of the Fire upon the Hops, in ſuch Manner that the top Part ſhall ſoon be as dry as the Bottom.

When all are dry enough the hinged Side is to be let down, and being ſupported ſlanting downwards with a gentle Deſcent from the Level of the Bed, the Hops are to be puſhed out carefully with a Board at the End of a Pole, and the Side being put up again all is to be continued in the ſame Manner, with a freſh Parcel of Hops.

To ſave the Expence of this Cover, a flat Scoop may be uſed to turn the Hops when they are two thirds done, but this is ſome Labour, and all Motion, as we have ſhewn, hurts the Hops; the Expence of the Cover need not be any thing like that of the Bed, for rough Boards will ſerve, and common Tin Plates nailed on will perfectly well ſerve for the facing of it. In this Manner the Price is moderate, but if it were much more it would be eaſily ſaved in a little Time, in the Advantage the Hops get by drying without turning.

CHAP. XVII.

Of the bagging of Hops.

OUR young Planter ſhall not be left at a Loſs in any Part of his Buſineſs, he has ſeen the Hop raiſed, picked, and dried, which laſt is the moſt nice and moſt expenſive Article of all; and we ſhall proceed now to the packing them up in Bags, after which they are out of his Hands.

We have directed that when Hops are to be dried, a Room is to be prepared for receiving them from the Kiln. This muſt be dry and airy, and there requires no farther Care.

The Hop being kept whole and clean, is a great Article in its Value: for this Reaſon, as well as many others, it is not to be packed up directly from the Kiln, for it is then very brittle, and would break in ſuch a Manner as to foul one another, and be full of Fragments. This would greatly reduce their Price. Beſide, they would have too much Heat among them, and this not going off freely would damage them. For this Reaſon they muſt lie in this Room till they have thoroughly cooled; and they will, in that Time, grow ſo tough and firm that they may be preſſed in packing without Fear of hurting them.

Three Weeks is the leaſt Time they ſhould lie for this Purpoſe, and according to the Seaſon, and other Accidents, it will be proper ſometimes to allow them a Month or longer.

If the Weather be moderate they will come to a proper Toughneſs very well, lying open; but if it be very hot and dry 'tis beſt to ſpread Blankets over them. So tender a Thing as the Hop very well perceives the Difference of Seaſons within Doors.

The Room into which the Hops are received from the Bed of the Kiln, ſhould be pretty near the ſame Level with the Bottom of the Bed, that the Hops may not be hurt by falling too far:

this alſo anſwers another Purpoſe in the bagging; for being at this Height there may be another Room under it, which is quite neceſſary for the managing that Matter.

In the Middle of the Floor of the Room into which the Hops are received from the Kiln, there muſt be opened a Hole communicating with the Room underneath. This muſt be four Foot long, and three and an half wide. The Bag into which the Hops are to be received muſt have a Hoop faſtened to its Top, the Edge all the Way round being turned over the Hoop, and faſtened with Packthread in a large Needle. This Hoop is to be of ſuch a Size that it cannot go through the Hole.

The Bag being thus prepared is to be let thro' the Hole, the Hoop ſupporting its Top remaining above; and this is to be very well faſtened in, becauſe it is to bear all the Weight and Force in the treading.

The Bag being let through, toſs in a ſmall Quantity of Hops, and then going into the lower Room, gather up ſome of them to the Corners, and tye in a ſmall Parcel into each Corner, with a Packthread put ſtrongly round. Theſe reſemble Toſſels or Pincuſhions, and are very ſerviceable afterwards in managing the Hops.

When this is done let more Hops be thrown in, and let the Man who packs get into the Bag, diſperſing them evenly, and treading them down as faſt as they are thrown in: this is to be done till the Bag is full.

When this is done the Bag is to be unripped from the Hoop, and its Top ſowed firmly together, making a couple of little Bunches at the Corners, as there were at the Bottom. This finiſhes the Management of the Hop; for in theſe Bags they are ready for the Market, and if the Owner have a Mind to wait for a more favourable Time for ſelling them, they will keep ever ſo long in a dry Room without Damage.

CHAP. XVIII.

Of the Management of the Hop Ground after the Hops are gathered.

WE have ſet out with ſuppoſing our Planter to begin his Work from the Ground, and have carried him through the firſt Seaſon. We have therefore yet given few Directions for the managing an old Hop Ground, our Subject haveing been a new one. We ſhall here enter upon the Care of the Ground after the Crop is gathered, and this will lead us to that Conduct which is neceſſary in Plantations that have been ſometime eſtabliſhed.

As ſoon as the picking is over clean off the Stems of the Hops from the Poles, and lay them up dry for another Year, the beſt Way is to place them in a Heap under ſome Shed. In large Grounds 'tis worth while to erect a Shed for the Seaſon of picking, that this may be done under Cover; and the ſame Building will ſerve for keeping the Poles till Spring. Some raiſe them in Heaps hollow within, and ſtanding like a Pyramid, but the Outſide Poles are damaged in this Way, and the Tops of all. Others lay them in Heaps expoſed, only ſpreading the dry Plants over them, but this rots them. The Method of houſing them is much better; and the Poles come ſo dear, and the Shed may be raiſed for ſo little, that 'tis worth while to do it only for that Purpoſe.

As to the Hop Ground, that is to be left untouched till Spring: but it will be needful to give it a good Dreſſing then, and therefore the Manure ſhould be got ready during the dead Seaſon. As the Planter uſed a Compoſt for the receiving his Sets at firſt, ſo he is to follow the ſame Method in dreſſing the Ground afterwards. Then let him be ſure to remember, on all Occaſions, Hops will be very much improved by Dung; but they cannot bear ſuch as is newe it will utterly deſtroy them. Upon the proper Condition of this Manure, and the due dreſſing of the Ground by Tillage, will depend the Succeſs of the next Year.

It is in the Planter's Choice to have a moderate Crop, or three Times as much, according to his Diligence and Conduct; and it is poſſible, by Neglect or Miſmanagement, not to have a third Part of what would naturally come.

Mix ten Load of Dung, that is at leaſt a Year old, with two Load of common Garden Mould; and half a Load of ſharp Sand, ſtir and work all this thoroughly together about NOVEMBER, and let it lie till Spring.

The laſt Week in MARCH plow the Ground lightly over, then bring out all the old Haulm or dry Stems of the Hops that were taken off the Poles the laſt Autumn, lay it in Heaps in different Parts of the Ground, and let Labourers ſhovel ſome of the Surface of the Ground upon the Heaps. Then ſet them on Fire and reduce them to Aſhes. Theſe Aſhes will lie in Heaps, and let the Compoſt laid together in NOVEMBER, be brought into the Ground, and equal Quantities of it laid on every Heap. Let a Labourer mix the Earth and Aſhes with the Compoſt, and this becomes an extreamly rich Manure, and agrees perfectly well with the Hop, though a difficult Plant.

As ſoon as this Mixture is prepared, which will probably be within the Week, or in the very Beginning of APRIL, let the Hills be opened, and they are to be refreſhed with it.

Let it not appear ſtrange to the Planter, that we adviſe the ſetting about dreſſing the Ground ſo late as in the Beginning of APRIL. We are ſenſible it is the Cuſtom of many to do it earlier, but Experience has ſhewn us this Time is much better. The Hop is a Plant that ſhoots late, and 'tis happy for the Planter that it does; for when a forward Spring brings the Shoots early, there generally happen ſome Injuries to them. This late dreſſing keeps them backward in ſpringing, and at the ſame Time thoroughly deſtroying the Weeds ſo late, they do not riſe of a conſiderable Time.

Theſe are the Reaſons for late dreſſing the Hop Ground: the Manner of doing it is this. The Hills are to be one after another pulled down, and the Roots examined. Theſe are of two Kinds, the old and the new; the old are all to be preſerved, and the new, which ſhoot Sideways

are

are to be cut away. The old Roots are reddiſh, and the new are white, ſo that the Colour eaſily diſtinguiſhes them.

But let the Planter remember that it is not all the new Roots which are to be cut off, but thoſe only which ſhoot ſideways. Such as run downwards are to be preſerved.

The ſame Diſcretion is to be uſed with the Shoots, the old Sets are to be preſerved, and here and there a good young one that is well placed, is to be left on with them, the reſt are to be taken off; they are ready for planting in new Ground if wanted, if not let them be thrown away.

When the Roots and Sets are thus cleared and prepared, let the Earth that was taken from them, and that removed by the breaking of the Hills, be thrown into the Spaces between the Hills; and let the Hills be made up to a due Height, with the mixed Compoſt and Aſhes, and calcined Earth, which together makes an excellent Manure. The young Shoots are to be cut off at an Inch from the old one this firſt Dreſſing, but every Year afterwards they muſt be cut away cloſe.

It will often happen that the Set of a good Hop degenerates into a wild Kind; in this Caſe let the Hill where this ſtood be marked at the Time of gathering; and at this Spring dreſſing let it be entirely taken to pieces, the former Sets removed, and ſome of the beſt of thoſe produced by the good Kinds be planted in their Place. The Hills muſt not be made too high at firſt, becauſe the Ground is to be pared in the Summer, as directed before, and theſe Parings are to be laid upon the Hills; ſo that if they were too high at firſt they could not bear this Addition, the Uſe of which we have ſhewn already.

As we have adviſed the dreſſing the Ground ſo late, the new Planter may be ſtartled to find ſome of his Hops up when he ſets about it: he is not to regard this, but to go on with his Work. The cutting off a Top at this Seaſon does no Harm: but this being once done, and the Hills made, let him take Care no Injury is done to them afterwards. All Vermin and all Poultry are to be kept off, and of all Birds he is to be the moſt aware of the Gooſe, the greateſt of all Enemies.

CHAP. XIX.

Of dreſſing an old Hop Ground.

THE Hop Plant comes to its full Vigour the third Year, and it will laſt a great while; but Time will wear out the Strength and Heart; and ſometimes Neglect will bring the Ground in a few Years to the Condition it would have fallen into neceſſarily after its full Period.

In either of theſe Caſes the ſame Method is to be followed. In this Circumſtance the dreſſing of the Ground muſt be begun in Winter, not ſtaying till Spring. Firſt let the whole Space between the Hills be plowed up with a four coultered Plow, that it may be cut deep and thoroughly broken: and let there be in readineſs ſome of the Compoſt before deſcribed. When the Spaces are thus broken up, let the Hills themſelves be pulled down as far as can be with Safety to the Plants, and let their Earth, and ſome of that which is neareſt them in the Spaces, be thrown to a Diſtance, and bring in the Compoſt to ſupply its Place all about them.

This deep plowing will deſtroy the Weeds perfectly, and the Addition of new Stuff will give the Hops the Advantage ſo far, of not only new Ground, but very rich Ground.

There is alſo another Advantage in this Method, which may be underſtood by the Principles of Huſbandry before laid down; this is, that the Hop is at once encouraged to ſend out new Roots, and Nouriſhment is provided for them.

To explain this perfectly, let us ſet before the Reader the real State of a decayed Hop Ground, as it would appear if the whole were expoſed to the Eye.

Here are a Number of Hills with ſtrong old Plants upon them, and here is a great Extent of Ground between and about them, which is hard and firm, at leaſt it is ſo at a little Depth.

The Surface of this Ground may have been ſtirred to four, five, or ſix Inches deep, but never more ſince the Ground was made: under that it is perfectly hard, as if never broken by any Tillage.

The Roots of the Hops we have ſhewn do not ſpread near the Surface, nor ſhould be ſuffered much to do ſo. Their common Way is to ſtrike deep into the Earth, and there to ſpread every Way to a great Diſtance. This is their natural Courſe, and in this they ſhould be encouraged; now let us conſider what is the Caſe of an old Hop Ground. The Roots have gone their Depth, and they cannot ſpread becauſe of the Hardneſs of the Ground between. The Earth in the Hills is all they have any Advantage from, and that in general is renewed too ſuperficially.

In this Caſe the Hop ſends its Roots but a little Way, and they lie in an Earth they have long before exhauſted. This is the Occaſion of their Decay. We ſee that by removing them into a new Ground, the ſame Plants ſucceed greatly, Nature therefore is not exhauſted in them. We have ſhewn how they come to loſe their Vigour: and we have ſaid at firſt, that at ſuch Time the common Practice is to ſet them in a freſh Ground, that in which they ſtand being worn out.

We have ſet this plain State of the Caſe before the Planter, to ſhew him that this is the Occaſion of the wearing out of the Ground; and as we are about to propoſe the renewing it by Tillage inſtead of giving it up, we ſhall ſhew the Reaſons.

We have delivered the Caution of planting the Ground with Fruit Trees in Time: ſo that the Perſon who chuſes to give up his Ground at the End of ten or a dozen Years, may do it to the beſt Advantage: but we here ſhall give him the Choice of reſtoring it to its Vigour, and continuing it in Strength from Generation to Generation.

CHAP. XX.

Of reſtoring a decayed Hop Ground.

IN the Condition wherein we have deſcribed the Hop Ground, the common Practice is to give it up; and this was very reaſonable upon the old footing of Agriculture, in which nothing was known but by Memory; Men practiſing what they had ſeen done before, and underſtanding nothing of what they did by Method. Now we are upon a new and better Syſtem.

On taking up a Root of an old Hop Plant in one of theſe decayed Grounds, the Fibres hanging from it will be found few in Number, large, and often mouldy, or otherwiſe decayed at their Ends. This is a State in which they can ſupport the Plant but very poorly. The large Roots in all Growths ſerve to receive the Nouriſhment from the ſmall ones, and convey it to the reſt of the Plant; but 'tis the ſmall ones that abſorb it from the Earth. There are few of theſe, therefore the others in a Manner loſe their Uſe, and the Plant is very poorly nouriſhed. There are no ſmall Roots to penetrate into the Ground, nor any Ground in a Condition to receive or ſupply them with Nouriſhment. Therefore to reſtore the Hop Ground to its old Vigour we muſt do two Things, and no more are neceſſary; we muſt occaſion the Plants to ſend out more Roots, and prepare the Land to give them free Paſſage, and afford them Nouriſhment.

How we ſhall go about to make the Plants ſend out new Roots, the common Practice of every Gardener ſhews us. When he is to remove a Plant of whatever Kind, he cuts off the Ends of all the Roots before he ſets it in the new Ground. The Effect of this is, that there immediately ſtrike out a great many new ones; and theſe being ſmall are in a Condition to imbibe Nouriſhment.

The other Article may be learnt alſo by the ſame familiar Example. When the Gardener has cut off the Ends of the Roots, he opens a Hole and ſtirs up the Ground about the Place. This diſpoſes the Mould to give free Paſſage to theſe new Roots, and to afford them Nouriſhment.

Now let us apply the Principles we have before delivered, and this familiar Example to practiſe in the reſtoring a decayed Hop Ground.

We ſay the Earth is exhauſted, but that is a Miſtake. The greater Part of it, that is, all in the middle Parts of the Intervals, lies hard and unpenetrated, and has done ſo for many Years, no Roots have got into this at any Depth, therefore this is not exhauſted. Now the Earth about the Hills being exhauſted, is to be removed, and freſh and better Matter to be put in its Place, and the other being thoroughly broken and divided by the four coultered Plow, will be ready to ſerve as new Earth in all Reſpects.

In plowing the Ground let the Plow come as near to the Hills as it can, and cut to the full two Spit Depth, particularly in thoſe Places. This will cut off the Ends of all thoſe Roots which ſhall have penetrated ſo far within that Depth, and the Ground being rendered light and fine by the breaking, will be ready to receive freely the new ſmall Roots they ſhall ſhoot from their Ends, and to afford them Nouriſhment. In the ſame Manner the Spade will, in digging down the Hills, cut off the decayed Ends of thoſe ſhorter Roots which never extended beyond the Hill; and not only a well broken Earth, but a perfectly new Earth will be added here for them to ſtrike into, and for the ſupplying them with Nouriſhment.

Thus by this double Management of the Hills and the Spaces, the Roots will be nearly all cut off at their Ends; they will be put in a Condition to ſend out new ones, and there will be Earth all about them to receive and ſupply them with Nouriſhment; and this is all that is required for the moſt perfect Growth of every Plant.

We ſee therefore in Reaſon, that a Ground thus treated ought to yield as well, and indeed better than a new one, becauſe of the eſtabliſhed Growth of the Sets: and I may almoſt venture to affirm, that it will anſwer exactly ſo in Practice. What I am propoſing to others I have tried myſelf in little; and am now practiſing at large. I mended one Corner of my Ground in this Way, and it anſwered to the utmoſt Expectation: I am now trying the ſame Courſe in the whole Ground, and have no Reaſon to doubt but the Succeſs will every where be equal.

When the Ground is thus run to Decay no Method is ſo good as uſing the four coultered Plow, becauſe of the Depth to which it cuts, and the perfect Manner wherein it breaks the Furrow; but when the Ground is once reſtored this Way, the common Horſehoe or Hoe Plow, called the Horſe-Break, is fully ſufficient. This is a new Practice, but it is founded on Reaſon, and ſupported by Experience in other Growths, nor can there be the leaſt Doubt of its full and entire Succeſs, according to the Promiſe of the Trial I am now making.

CHAP. XXI.

Of watering a Hop Ground.

THERE remain yet ſome few Particulars to be mentioned, as to the Management of a Hop Ground; and theſe as they are not general, and at all Times neceſſary, we have referred to this ſubſequent Place of Conſideration, that we might not break the Chain of neceſſary Works in every Ground, and for every Seaſon.

The Principal of theſe accidental Articles is watering. It is not neceſſary every Year; and happy for the Planter that it is not, for 'tis a Buſineſs of great Fatigue; but ſometimes, whatever be the Expence or Labour, it will be found worth while to do it.

This depends upon the Seaſons. When Nature follows her uſual Courſe the Planter muſt give himſelf no Trouble to aſſiſt her; but he is to know what Aſſiſtance ſhe ſhould afford, and when that is wanting he is to aſſiſt her by Art.

Thus Spring is a Seaſon in which there are

Showers,

Showers, Nature intends this, and all Vegetables require it: but there are Seaſons in which the Courſe of Nature is prevented, interrupted, or ſtopped: in theſe let the Planter in the Hop Buſineſs aſſiſt her at whatſoever Expence.

No Plant requires the Spring Rains more than the Hop: ſome will do without them for the Time, and recover afterwards when Rains fall, if ever ſo late; but if the Hop be defrauded of its due Watering in Spring, it will be ſeen in the Fruit in Autumn. The Planter being informed of this, will know it his Intereſt to give the Aſſiſtance Nature chances to withhold.

We have for this Reaſon obſerved, that in the Choice of a Piece of Ground for Hops, the Planter ſhould, if poſſible, fix upon a Place where there is Water near.

The Time of watering Hops is a material Conſideration. We have obſerved that it is not to the Advantage of the Hop to ſhoot early, becauſe the Plant is by that thrown in the Way of many Accidents: therefore the Time of watering is not early, becauſe Water will promote their Shooting.

The firſt Seaſon is juſt before the Ground is pared, and the Hills made up. This will diſpoſe the Hops to ſhoot vigorouſly juſt when it ſhould; that is, juſt when the Hills are in a Condition beſt to ſupport their Growth.

If the Seaſon prove tolerably favourable, the Trouble of watering concludes at this once; but if no Rains fall in the following Month, it muſt be repeated at the End of that Time; and if the enſuing Summer continue dry, it may be repeated once more about the Time of the Hops flowering, with great Advantage. Nothing contributes to fill and perfect the Hop ſo much as a proper Degree of Moiſture at the right Seaſons,

In the watering the Hop Ground, a ſufficient Quantity is to be allowed: to do it ſlightly is not to do it at all, the Planter throws away his Expence, becauſe he grudges to do what is ſufficient: the Hop is a large Plant, and great Supplies both of Water and Earth are to be given it, or it will never be able to ſupport itſelf to any Advantage.

Every Time the Ground is watered, let the Spaces be pared afreſh, and the Parings added to the Hills; this keeps in the Moiſture, and defends the Roots and Stems towards the Bottom, where they are moſt capable of Injury from the great parching Heat of the Sun. The Vapour of this Water alſo aſcending through theſe Parings, mellows and ſoftens them, ſo that they become an excellent Manure as well as Shelter; and the Weeds are deſtroyed by the ſame Operation: ſo that in this Article thus conducted, nothing leſs is done than this; the Hop Roots are refreſhed, the Land is not exhauſted by Weeds, and it is given to the Plants in the beſt poſſible Condition for their Support.

Sometimes particular Plants of the Hop will ſucceed but poorly, or ſingle Hills will dwindle when the reſt of the Ground is flouriſhing enough: in this Caſe as the Diſorder is particular, a particular Remedy is to be applied.

Let theſe Hills be watered frequently with Water in which Pigeons Dung is mixed; making a Baſon round the Plants, that none of the rich Water may be loſt. If this does not ſucceed, let the Hills be carefully opened, and let ſome Hogs Dung mixed with ſome rich Earth, be put in about the Roots.

About Novemrer let the Ground be particularly well dug, and broke round theſe Hills, and they will by this Management equal, if not exceed the beſt of the others.

Having thus laid down the Method of managing the Hop Ground from the Beginning to the End of the Work, we ſhall communicate to the Publick certain Improvements upon the common Practice made by others. They have fallen into our Hands in the Form of Letters, from various Perſons, in Conſequence of thoſe Advertiſements, wherein at the firſt ſetting out of this Work, are requeſted the Aſſiſtance of all who had practical Knowledge, and had Generoſity of Spirit to communicate that Knowledge for the publick Good.

We have not inſerted the Subſtance of them in the Chapters, where we have treated of the Articles they concern, partly becauſe not having experienced them ourſelves, we have no right to recommend them to the Planter as certain Practice; and, partly, that we might not defraud their Authors of the Merit of them. We believe them to be right and uſeful, otherwiſe we ſhould not have inſerted them, but the ſureſt Method of knowing will be by Trial, to which we recommend them, not doubting the Succeſs, though we are not able from Proof to inſure it.

LETTER I.

On the Choice of Ground, and Manner of Planting.

SIR,

" If the Experience I have had in the Hop " Way is of any Uſe, I ſhall be glad to ſerve " you. In the firſt Place, if you expect a good " Ground, let it be free to the Air. I find " wherever the Air can't get through, Hops " blaſt, and in the Middle of the Ground they " ſhall be all ſpoiled, at the ſame Time they " are quite good at the Sides. One great Elm " in a Neighbour's Ground has ſpoiled me many " a Bag of Hops, it ſtands juſt where the Air " ſhould paſs; and there are two others behind " it, ſo that I am then quite choaked up: my " Hops for eight, ten, or a Dozen Hills juſt " there are many Years ſpoiled, while all the " reſt are in Order.

" I find it inconvenient to have all my Hops " ripen at a Time, for there is oftentimes no " getting Hands enough to manage them. For " this Reaſon I now plant three Sorts; the " Early-white, the Long-white, and the Oval. " The firſt of theſe ripens a Fortnight before " the two others, and the Oval is commonly a " Week later than the Long-white. So I have " three Seaſons. The Early-white don't yield " a great Crop, but they come early to Mar- " ket, and fetch a Price, ſo I find one Thing " anſwers for another: and this I know, ſince " I followed this Way, I have always more

" Profit than I uſed to have, and not half the
" Trouble. If others will do the ſame, they'll
" find the Truth of what I ſay.

I am,

With Reſpect,

Your humble Servant,

Arthur Collins.

LETTER II.

On the Planting and Management of Hops the firſt Year.

SIR,

" Whereas it is the common Way to plant
" four Sets of Hops in a Hill, one at every
" Corner, I bethought me in planting a new
" Hop Ground, to try Practices, and plant
" more: ſo in ſome I put twelve Sets, three on
" each Side, in other ſome ten, in ſome eight,
" and in others ſeven, ſix, five, and others
" four; in ſome alſo I put only three, and in
" others two, and in a few but one Plant a-
" piece, ſticking it juſt in the Centre.

" Now by what I find after many Years
" Tryal in this new faſhion'd Hop Ground,
" our Planters have not found out the right
" Number. Where I have only one Hop in
" a Hill, it bears full as much as two in the
" common Way; and where I have ten or a
" dozen, they ſtarve one another, and don't
" yield ſo much as four. I find therefore upon
" the whole, that placing the Hills at the com-
" mon Diſtance, each will very well feed ſix
" Plants, if the Ground be well tilled between,
" and they will yield every one nearly as much
" as one where there are only four. But ſup-
" poſe the ſix thus yield as much as five, when
" there are only four on a Hill, ſtill it is gaining
" a great Advantage.

" I find that my ſingle Plants are liable to
" feweſt Damages, and the thickeſt planted to
" moſt: but I don't ſee any material Differ-
" ence in that Way, between ſix and four on
" a Hill. This I thought good to tell for the
" Benefit of others, depend upon it ſix Plants
" in a Hill is the beſt Number can be raiſed.

" There is one Thing more it may not be
" amiſs to tell you of. We have got a Way
" here of loſing the firſt Year of a new Hop
" Ground, having a Notion that to let the
" Plants bear the firſt Year, weakens them for
" ever afterwards. I'll tell you how that is. If
" the Ground be planted in Spring, as ſome do
" it, then there is ſo little Time between that
" and the Hop Seaſon, that there will be a
" ſmall Produce, and it will be better to pre-
" vent than encourage it, for the Plants had
" better be rooting than yielding a few ſcatter-
" ing Fruit: but the right Seaſon of planting is
" the Beginning of OCTOBER, and in that Caſe
" the Sets root before the Cold of the Winter,
" and have Time to ſtrengthen themſelves in
" the Ground before the Spring ſhoot. They
" will therefore come up ſtrong, and as well
" as ſome Spring planted Hops the ſecond
" Year. In this Caſe they will yield a very
" good Gathering the firſt Summer, and it is a
" very idle and waſteful Thing to neglect ga-
" thering of them. I have found it thus in
" many other Things concerning Hops: People
" follow one another's Practice right or wrong,
" without conſidering that what is right in one
" Reſpect, may be wrong in another."

I am,

SIR,

Your humble Servant,

LETTER III.

On the picking of Hops.

SIR,

" I have found many Inconveniencies attend-
" ing the uſual Way of picking of Hops in the
" open Ground, for which Reaſon I have now
" many Years built for that Purpoſe. I am
" ſenſible the Name of Building is enough to
" ſtartle People not uſed to theſe Things, but
" mine is only a Shed, the Coſt very little, and
" the Convenience great on many Occaſions.
" My Shed is only a Top, two Ends, and a
" Side, being open all the Length one Way;
" and the Materials of the cheapeſt Kind. The
" Length is two and twenty Foot, and the
" Breadth twelve. This conveniently holds
" two Frames in the picking Seaſon; and at
" all other Times it ſerves to houſe the Tools,
" to put by any Thing like to be wanted,
" and in Winter to lay by the Poles. I never
" have my Poles above twenty Foot long, ſo
" there is two Foot over Room to hold
" them.

" In the picking Seaſon I ſet up two Frames
" lengthways in the Shed, and have juſt Room
" for the People to ſit Back to Back between
" them.

" My Frames are ſeven Foot and a half long,
" and three and a half wide; they are made
" of nothing but four Poſts for Corners, ſet up
" firm in the Ground, with a Hair-cloth tack-
" ed over them, and a Couple of Forks to
" hold up the Poles. The Poles are laid over
" theſe, with the Vines over them, and the
" Pickers work along the Sides, and at the
" Ends, picking the Hops into the Cloths.

" Thus I find no Damage nor Danger from
" Wind, Sun, or Showers, and my Work in
" every Reſpect goes on better than my Neigh-
" bours.

" Many of them make the ſame Sort of
" Frames that I do, removing it from one Part
" of the Ground to another; but I have always
" found the fixed Shed beſt, and mine are not
" ſmall Grounds. The Poles are ready to be
" laid up, and there is no Danger of Acci-
" dents. My Hops are picked clean and dry,
" and they are not afterwards broke by tum-
" bling about, for it is only taking up the
" Ends and Sides of the Hair-cloth, and they
" are carried away as it were in a Bag directly

" to the Kiln, where they are emptied into " the Bed for drying."

SIR,

Your very humble Servant,

R—. R—.

CHAP. XXII.

Of Flax.

THE Value of Flax is encreaſed by the eaſy Manner in which it is to be cultivated. Scarce any Produce whatever may be made to bring in greater Advantages, and none is ſo much neglected. We import from Abroad at a great Price, what we might raiſe as well at Home; nor is there any Thing to diſcourage us from the Attempt. We have laid down in the ſeveral preceding Chapters, the Method of managing Hops; an Article of Difficulty, which yet in many Places is executed with great Familiarity; and, we hope, from the light wherein we have ſet it, that it will be in many more.

What we have to ſay of Flax, though we ſhall deliver its Management as fully, will be comprized in a much ſmaller Compaſs, and the Trouble of the Perſon who ſhall be induced to raiſe it, will come in a much ſmaller and ſhorter Way.

Flax is a ſlender, tall, and pretty looking Plant. It is too tender to keep itſelf well upright ſingly, but in a Field where it is ſown together in a Body, nothing ſtands better: this is the Caſe with Wheat, which if a ſingle Stalk were raiſed, would not be able to ſtand before the Wind; though in a Field it very well ſupports itſelf.

Flax is an annual Plant. Its Root is ſmall and fibrous, and periſhes as ſoon as the Seed is ripened. The Stalk is round and ſmooth, and it riſes to three or four Foot in Height. The Leaves are ſmall and narrow, and of a pale green. The Stalk grows ſtrait and ſingle to the Top, where it divides into three or four little Branches, and on theſe grow the Flowers, and after them the Fruit, containing ſeveral Seeds. The Flowers are large and blue, ſo that when the Plant is in Flower a whole Field together, it makes a very beautiful Appearance.

The Plant is thus known at ſight, and is very pretty; the ſlender upright Stalks, ſmall Leaves, and large blue Flowers diſtinguiſh it: when examined more nicely, each Flower is found to ſtand in a ſmall green Cup, made of five pointed Leaves: the Flower itſelf in the ſame Manner conſiſts of five Leaves; they are narroweſt at the Bottom, and widen all the Way to the Top, ſo that the whole has the Shape of a Funnel. In the Center ſtand five very ſhort Filaments, each having at the Top a Knob or Button, ſhaped like an Arrow's Head; and in the Centre of theſe is the young Fruit, on which grow five very ſhort and ſmall Threads, bending at their Tops, and having no Knobs or Buttons on them.

We have ſhewn that in the Hop thoſe ſmall Knobs on the Filaments, contain a Duſt that impregnates the Fruit, and perfects the Seeds; they are of the ſame Nature in this, and all other Plants, but in this, as in moſt others, they ſtand together with the Rudiment of the Fruit, in the Bottom of one and the ſame Flower: whereas in the Hop, and a few others, they grow in different Flowers upon the ſame, or upon different Plants of the ſame Species.

The Huſbandman will not be diſpleaſed that we thus inform him of the Structure and Nature of Flowers; we would have him ignorant of nothing that relates to his Profeſſion, and this is no idle Curioſity: he who beſt underſtands Plants, will be able beſt to raiſe them.

In Books of Botany theſe Things appear very intricate, but we have explained them in a few familiar Words.

When the Duſt from theſe Buttons has ſhed itſelf upon the crooked Filaments which ſtand among them, and which riſe from the young Fruit, the Leaves of the Flower fall off. Although they are the gaudieſt Part of the Plant, they are of no other Uſe than to defend theſe little regarded Threads from Injuries, while their Duſt is ripening. As ſoon as that has ſhed itſelf upon the Points, which riſe from the Rudiment of the Fruit, they die away and fall off. The Threads themſelves alſo fall off, and as in this Caſe of the Flax, ſo in all others, nothing remains but that Rudiment of the Fruit or Seed Veſſel we have deſcribed. This encreaſes in Size, and when ripe, is a Seed Veſſel of a roundiſh Shape, but marked with five ſlight Ridges, and terminates in a Point. It contains ten ſeparate Cells or Compartments, in which there are contained the Seeds: theſe are of an oval pointed Form, ſmooth, flatted, and brown, and there is only one of them in each Diviſion or Cell of the Head.

This is the Deſcription of the Herb which affords our Linnen. It has been known in very early Ages, the GREEKS having called it by the ſame Name, and uſed to the ſame Purpoſes with the preſent; and it ſeems to have been originally a Native of ſome of the Eaſtern Countries, though it is not eaſy to trace its Time of being brought into the North: at preſent 'tis cultivated in moſt Kingdoms, and as we ſhall ſhew, deſerves to be much oftener raiſed in ENGLAND.

CHAP. XXIII.

Of the ſeveral Kinds of Flax, and Choice of the Seeds.

'TIS one Thing to ſpeak as a Botaniſt, and another as a Huſbandman, this is ſeen in treating of the Kinds of Flax: the Curious in Plants reckon up no leſs than twenty, but the Farmer needs to know but one.

We ſhall not farther particularize this, than that it is the Flax juſt deſcribed, and is the only Kind raiſed any where for Uſe.

We ſee a Kind of Flax wild about the Bor-

ders

ders of Fields in ſome Places, and it has been diſtinguiſhed by ſome as different from the other, but it riſes from Seeds of Flax ſcattered by Accident, and only differs from the right Flax in being ſmaller and weaker, as Things that run wild always do from ſuch as are cultivated.

In a Crop of Flax a great deal will depend upon the Goodneſs of the Seed; and we find too often that this ripens but poorly in England.

We have ſhewn on another Occaſion, that moſt of our Neighbours import the Seed of their Flax from Flanders; but it is better to get it from the Eaſt. Every Plant has its native Ground on which it riſes to the greateſt Perfection, its ripening the Seed is the compleat Perfection of its Growth: and this will be beſt done where it is native.

We have obſerved, that it is natural to ſuppoſe Flax originally came from the Eaſt, and there is this Evidence in Support of the Conjecture, that it no where ripens its Seed ſo well.

For this Reaſon, that the Farmer may ſet out right in this Undertaking, we adviſe him to get his firſt Seed from the Levant, enough of it is imported every Year, only let him take Care to enquire for the right Sort, and to deal with a Perſon of Integrity who will not deceive him.

When he has got a Quantity of this, right and fine for his Purpoſe, it will be ſufficient for ſome Time; the Seed of his own Growth raiſed from this, will be good three Crops, if it ripen favourably, ſo that he need not have any more for four Years; but by that Time, in Spite of all the Care he can employ, he will find it begin to run weak, and then he muſt have a freſh Parcel from the ſame Place.

We ſhall lay down the Rules by which our Huſbandman may be ſecure of raiſing a profitable Crop of this Commodity; but let him take Care that he make no Miſtake in the Seed: that would be a Fault no ſucceeding Care could remedy: ſuch a Stumble at the Threſhold would keep him for ever out of the Houſe.

CHAP. XXIV.

Of the proper Land for Flax, and the preparing it.

WHEN the Huſbandman has got his Seed, the next Thing is to conſider on what Parcel of his Land to ſow it. Flax will grow on almoſt any Soil, but it will grow where it will not thrive, and in this Caſe there will only be the Amuſement of looking at the Beauty of its Flowers, for there is to be expected little Profit.

To raiſe it to the moſt full Advantage, it muſt have the beſt Ground that can be given it. Flax, though a ſmall rooted Herb, exhauſts a vaſt Quantity of Nouriſhment. Inſomuch that it will impoveriſh the richeſt Piece of Ground in a little Time, but it very well pays the Damage.

The Field to raiſe it to Advantage, muſt have a light deep mellow Soil, the more like Garden Ground the better, and it will never ſucceed ſo well as when it comes upon a new Piece of Tillage.

As to the Choice of Soils, a rich Loam is by much the moſt proper for Flax: and inſtead of following almoſt any other Crop, tho' with the beſt Dreſſings, to prepare for it; 'tis much the beſt to ſow it on new broke up Ground.

The converting of Paſture into Arable, if the Soil ſuits Flax, is a very beneficial Opportunity for the ſowing of it; but it will ſucceed beſt upon a broke up Saintfoin Lay; for the Flax roots very ſhallow, and the Saintfoin very deep, ſo that the Surface of the Ground, which is all the Flax meddles with, is left quite unexhauſted.

On ſuch a Field with a proper Soil and good Seed, Flax will yield a more profitable Crop to the underſtanding Farmer, than any Thing whatever; but in this Caſe, to continue the Benefit of ſuch Crops, he muſt change not only his Seed, but his Ground at proper Seaſons, for the ſame Land will not, with any Management whatever, bear many ſucceſſive Crops of Flax to the Owner's Advantage.

This uſeful Product is an Exception to what has been ſaid concerning the new Method of Huſbandry by the Drill and Hoe Plow. Mr. Tull has ſaid, and his Followers have repeated it after him, that by his Method of hoeing between the Rows, one Piece of Ground will be enabled to maintain the ſame Kind of Crop ever ſo long. Flax, whoſe Culture probably Mr. Tull had not experienced, proves the contrary; for Trial has ſhewn that no Culture or Management whatſoever, will enable the ſame Piece of Ground to bear Crop after Crop for ſeveral Years.

We do not give this as a Proof that the new Huſbandry is not proper for Flax; on the contrary, there is no Crop whatſoever wherewith it ſo well agrees, nor is this to be raiſed any Way with near the Benefit that it is by the Drill and Hoe Plow; but ſtill the ſame Land will not continue to yield it well. Half a dozen Crops are the moſt that can be got from a good Field by this Method; and it is not eaſy to get more than four by the common Huſbandry.

After this the Field muſt be well manured for preparing it to raiſe ſome other Crop, and the next ſowing of Flax is to be upon ſome other Ground.

What we have ſaid of the new Huſbandry in general, is thus explained under the ſeveral Particulars: it is better than any other Method; but it does not come up to all that has been written of it; and though it may in many Places ſupply the Uſe of Manure, yet to have the greateſt Advantage, both muſt be uſed together.

The Farmer has got his Seed of the right Riga Kind, and he has fixed upon the Piece of Ground where he will ſow it; the next Thing then is to prepare for its Reception.

The great Points here are two. To break the Earth very fine, for the Roots of Flax are ſmall; and to keep down Weeds.

We ſuppoſe the Piece of Land to be new broke up for Flax, and in this Caſe it is to be wrought over ſeveral Times, to reduce it to the needful

needful Fineneſs, it will be worth while to beſtow good Pains upon it for this Crop; and the Flax will never thrive ſo well as if it be ſown on Land laid as Level as the Border in a Garden.

Let the Ground have the laſt working about the third Week in March, and then let the Seed be ſown. This is an Article which we ſhall conſider ſeparately, as there are two diſtinct Ways of doing it, that by the Drill and the common Way by Hand; and on the former we ſhall be more particular, becauſe we have Experience upon a Trial, which perhaps no others have made in this Kind. We wiſh to ſhew with Impartiality, all the Advantages of the new Huſbandry, and although more has been ſaid of it than is true, this Species affords us one, and that very conſiderable.

CHAP. XXV.

Of the ſowing of Flax.

THOSE who have written of the ſowing of Flax all mention the doing it by Hand, for there are none who name this Species that have written ſince the Horſehoeing and Drill Huſbandry have been brought into Uſe. We have Proof that Flax is to be raiſed in very good Crops by the common Method, but Experience ſhews that it may be raiſed much better the other Way.

The great Damage done to Flax in its Growth is by Weeds; and theſe can no Way be deſtroyed ſo perfectly as by the Horſehoeing Method. The Reaſon that Weeds do ſo much Damage to Flax is, that in its firſt Shoot it is for ſome time very weak. In the common Methods of Huſbandry the Weeds riſe with it, and they being ſtrong and the Flax weak, they get the better of it; rob it of its Nouriſhment, ſtunt it in its Growth, and it never recovers. This the Perſons who raiſe Flax very well know, but they do not know how to prevent it: they have tried many Methods, but ſome of them have been fruitleſs, others prejudicial. It is for this Reaſon we recommend the Horſehoeing Method for Flax, the Succeſs of which we have proved by Trial.

However, as ſome may be bigotted to the old Way, we ſhall lay down the needful Directions for doing it in the beſt Manner, according to that Practice; and afterwards proceed to the other.

If the Farmer chuſes to raiſe Flax according to the old Method of Huſbandry, he muſt lay his Ground flat and even, with all the Clods broke, and the whole fine like a Garden Border; then he muſt ſee his Seed ſown by Hand, in the moſt careful Manner, by ſingle Caſt. This done he is to go over the Land lightly, with a Couple of fine Harrows joined together, and having thus covered the Seed he is to leave the reſt to Nature. The Time of ſowing Flax is the laſt Week in March, but if the Weather be cold it may be deferred till the Beginning of April. The Flax will be ſure to ripen for Uſe if ſown in the Middle of April, but unleſs it be got into the Ground early, the Seed does not ripen to ſo good Perfection.

We have ſaid when the Farmer has let his Seed into the Ground, and covered it with the Harrow, he is to leave it to Nature: it is not that the Flax wants no farther Care, but he can do no more for it. There is no Growth that has more Need of proper Management afterwards, but in this Way of raiſing it there is no doing the Crop that needful Service.

Weeds will grow up among the young Crop; the wetter the Spring the more of them; and we have ſhewn the Damage they do to Flax, but what is he to do, he cannot get in to hoe them up?

One Practice there is in this Way, which is the turning in of Sheep, but though this may be of Service, it is capable alſo of doing great Harm; ſo that it muſt be done with Caution.

When the Rains of the Spring have filled the Flax with Weeds, ſome have ventured to ſend in Weeders, but their Feet do more Harm than their Hands can do Good.

The other Method of turning in Sheep is much better, but the Time muſt be hit very nicely; if the Flax be too low they will tread it down and deſtroy it; and if it be grown to ſome Height, and the Stalk firm, they will break it with lying upon it, and it will never well recover.

Theſe are the Diſadvantages of Sheep turned in upon a Growth of Flax, but if the Huſbandman can hit the exact Time it will do very well, there is a Length of the Flax at which it will not be in Danger of being trampled in by the Sheep; and at which it will riſe again after their lying upon it. This is when 'tis about five Inches high; and if Sheep are turned in upon the Ground then, they will eat up the Graſs and Weeds; and the Flax, receiving little or no Damage, will ſtand the reſt of its Time free from its worſt Enemies.

This is the Method of managing Flax from the Seed to the full Growth, according to the common Methods of Huſbandry, but we ſee this is hazardous and imperfect: the Seed is ſown at Random, and there is great Danger that in deſtroying the Weeds the Crop itſelf is hurt. The ſame Advantages are procured in a cheaper, eaſier, and more certain Manner by the new Huſbandry; and the Method of raiſing it is this.

The Land is to be prepared in the ſame Manner for this, as for the other Method; and the Seed is to be ſown in treble Rows by the Drill, properly ſet for that Purpoſe, leaving the Partitions ſeven Inches broad between Row and Row, and the Interval between every three and three as ſmall as will admit the Horſehoe or Hoe Plow; for there requires no more Space between than is juſt ſufficient for performing that needful Operation.

In the common Way of ſowing by Hand, three Buſhels of Seed are uſually allowed to an Acre, when it is the freſh Eaſtern Seed, and all very fine and full, half a Buſhel leſs will do; in the Drill Way one Buſhel is enough for an Acre, and the Stalks riſe more numerous, and grow tenderer and finer for it.

As ſoon as the Seed is in the Ground let the Huſbandman prepare for hoeing. He is not ſo much to mind the ſhooting of the Flax, as the riſing of the Weeds; and this is a Seaſon when they will be very ſpeedy and very numerous. The young Crop ſhould have all the Nouriſhment the Land affords, therefore theſe are to be deſtroyed in the very Act of riſing. Let the Intervals be turned up with the Hoe Plow upon the firſt Appearance of any Weeds, and this will anſwer ſeveral excellent Purpoſes: it will deſtroy thoſe Weeds, and at the ſame Time prepare the Earth of the Intervals, to admit the Roots of the Flax freely, and they will be well ſettled in it in the Midſt of their proper Nouriſhment, before any ſecond Crop of Weeds can riſe.

As ſoon as the Flax has got a little Height, let Hoers be ſent in with Hand Hoes to clear away the Partitions; and thus the Growth will have all the Nouriſhment the Earth can afford for its firſt Shoot, which will be vaſtly ſtronger than it is to be obtained any other Way. By theſe Means the Flax will get ſuch a Footing in the Ground, before any other Crop of Weeds can riſe, that it will be too ſtrong for them. As they would have ſtarved the Flax before, that will now ſtarve ſuch of them as riſe in the Partitions, ſo that it would do without any more hoeing there; however, there is no Harm in repeating it by the Hand Hoe, in thoſe ſmall Spaces; and as to the Intervals the Huſbandman is to keep a watchful Eye upon them, and to repeat the Horſehoeing as often as he ſees any Parcel of them riſe, that would exhauſt the Ground, and tend to impoveriſh the Crop.

Theſe repeated Horſehoeings are ſo many freſh Dreſſings of the Ground, ſo that the Crop has new Benefit every Time. No Growth requires this Aſſiſtance ſo much as Flax, therefore the Horſehoeing Huſbandry can never be more proper than for this Species; and the Encreaſe in Growth will very well pay the Trouble and Expence.

What we can ſpeak from Experience is but in a Tryal, but we have Reaſon to imagine from that, that if the Crop of the ſame Quantity of Ground, by the common and new Method were pared, the Profits of that in the latter Way, after all Deductions, would be double.

CHAP. XXVI.

Of the pulling of Flax.

WE have conducted the Farmer, to whom the Culture of this Species is new, from the Choice of his Seed to the full Growth of the Plant, whether he chuſe to raiſe in the common old Method, or by the new. He has nothing to do but to watch its ripening, and to gather it. This however is an Article on which he muſt beſtow a great deal of Attention. There is a peculiar Period at which Flax is fit to be gathered, and this muſt be watched, and the Opportunity ſeized as ſoon as it offers; all before this being wrong, as well as after it. We ſhall endeavour, as particularly as ſuch a Thing can admit of a Deſcription, to ſettle the exact Time.

In the firſt Place it is to be conſidered, that the Uſe of Flax is of a particular Kind. Other Crops are raiſed for their Seed or their Roots, but this for the Stalk; which is to be manufactured in a ſingular Manner, and will yield to the Operation better or worſe, according to the exact Time at which it was pulled.

In other Kinds the Ripeneſs of the Seed, or the Bigneſs of the Root, are the Marks of their being fit for gathering, but in this it is the due Condition of the Stalk. Thoſe Marks are viſible and obvious to the Eye; this is the more difficult to be known, and therefore it muſt be watched the more narrowly.

The Farmer is to conſider, that although the greateſt Part of his Flax is to be pulled for the Stalk, it is proper to let ſome ſtand for Seed.

This makes a different Period of gathering, for if the whole were to ſtand till the Seed was ripe, it would be of little worth. Therefore let the Owner firſt ſet off a Part for ſtanding for Seed, and let this be upon the Edge of his Ground that is beſt defended from Winds, and where there is moſt Sun. If there be a Part open to the South, and backed by a good Hedge, this is the Place. Let him mark out by Stakes what Quantity he will have there for Seed, and then watch the reſt for ripening, only giving Directions to the Pullers to ſpare the Seed Parcel. This particular Part is to ſtand till the Seed Veſſel is very dry and ready to open, and the Seeds, upon opening it, are found to be full and firm. This Degree of Ripeneſs is eaſy enough known, ſo there needs no great Care on that Head; but before this he muſt look narrowly into the other.

It is a very common Practice to ſpoil the whole Crop for the Sake of the Seed. The Owners acknowledge, that if pulled while the Seed is young, the Flax will be the better, but that the Seed will be good for nothing; they therefore let it ſtand till the Seed has juſt begun to ripen, and then pulling it the Seed they ſay will harden and perfect itſelf in the drying.

Thoſe who follow this beaten Path muſt ſee their Flax out of Flower, before they examine it for gathering: they muſt then watch when the Heads turn brown, and begin to bend down the Tops of the Twigs whereon they ſtand, for that is juſt the Time of pulling this Way; but as the Flax is ſure to be much the worſe for ſo long ſtanding upon the Ground, it is much better to ſet aſide a Part only for the Seeds, and pull the reſt when it is in its Perfection.

We would fain lead the English Raiſers of Flax, into this beneficial Way of conducting themſelves. We are ſenſible that our Flax is inferior in its Quality to that of many Parts of Europe, where they have no natural Advantages over us for its Growth, but only underſtand its Management better. The great Article is their pulling it before it is too ripe.

In the Eaſt they ſow particular Spots with Flax purpoſely for the Seed, chuſing for this Purpoſe warm Situations and the richeſt Soils. This is one Reaſon why their Seed is ſo fine, their taking ſuch perfect Care in the Productions

of the Seed Plants, and nurſing them up purpoſely and only for it. We confound the two Purpoſes of ſowing together, we will have our Flax ripen its Seed, and yet be fine in the Stalk, which is impoſſible. Both in the LEVANT, and in thoſe Parts of the LOW COUNTRIES, and everywhere elſe in EUROPE, ENGLAND excepted, when they ſow Flax, they have their large Fields raiſed for the Stalk, and particular Spots for Seed. They can therefore pull their Flax for Uſe juſt at the Time when it is fitteſt, and therefore their Manufacture from it exceeds ours both in Strength and Colour.

Let us here take Example by thoſe other People; there cannot be any Error in following the Steps of thoſe who we ſee excel us in the ſame Article. We have not here laid down their Method of raiſing ſeparate Parcels for Seed on diſtinct Spots, it is ſufficient that our Huſbandman ſo far imitate them, as to ſet apart a certain Parcel of his common Growth for that Purpoſe, chuſing that which has moſt Sun and Shelter.

When the two Conſiderations of Seed and Stalk are thus ſeparated, they will be both better underſtood and better managed. The Huſbandman is to let his Seed Quarter ſtand its Time, but he muſt have an Eye upon the other as it riſes to flower.

In the common Method of Huſbandry the Flax flowers irregularly in the ſame Field. Some of the Seed having been buried deeper, and ſome ſhallower, there has been more or leſs Time required for their riſing; and the ſame Difference is preſerved in their coming to flower: alſo ſome of the Seed lying ſingle and at a Diſtance, and there being Heaps in other Places from this random Method of ſowing, that alſo will make its Share in the Variation; for ſuch as ſtand ſingle will flower a Week before thoſe which are in Cluſters, becauſe of their having more Strength.

From theſe different Cauſes a Field of Flax ſown by Hand, flowers very irregularly, ſome Plants ſooner, others later; and this is a vaſt Diſadvantage in a Crop which ſhould be pulled at one exact Time, and that Time determined only by the flowering.

This affords one Inſtance among many, why the Drill Huſbandry is much better than the common for the raiſing of Flax: for in that Method all the Seeds being let in at the ſame Depth, and diſpoſed with an even Regularity, both the above-mentioned Occaſions of the Difference in coming to flower are prevented; and it is a beautiful Sight to look upon a Field of this Growth, raiſed in this Way, the whole Crop being of the ſame Form, and the ſame Height throughout their Growth, and all burſting out into a Celeſtial Blue together. There is nothing reſembles the Brightneſs and Beauty of ſuch a Crop in Bloom, but a perfect clear Sky in Summer.

This is a very obvious Mark, and this is the Token for gathering. When the Flax is raiſed ſingly for the Manufacture, it is to be pulled as ſoon as ever it is in full Flower, the proper Time is before one Flower falls.

Let the Owner therefore only watch its Bud: when that burſts let him have his Pullers ready, and as ſoon as all the Plants are in full Flower, and there appears the firſt Mark of fading in any of them, let them be ſent into the Field. The more there are of them the better, for the Work would be to pull it all in one Day if poſſible.

This Practice is founded upon the plaineſt Reaſon.

The Flax is an annual Plant: the Purpoſe of Nature is its ripening its Seed, and when this is done it periſhes entirely. The Uſe we make of the Stalk is accidental, in Reſpect of the Plant's Growth; and we are to ſeize the Period accordingly.

The Articles of Value in the Flax are the good Colour, and the Firmneſs of the Threads in the Stalk: now theſe Threads arrive at their Perfection when the Plant flowers. They have been gradually coming up to it before, and from that Time they are gradually declining from it; therefore that is the Period of Perfection, and at that they muſt be taken; in all Things when Perfection is attained, the next Step is toward Decay.

While the Flax is growing to its Height, the Threads in the Stalk are green and tender; when it has arrived at its full Growth they are white and firm, and as ſoon as that Period is elapſed they grow brown and harſh. This Period is very ſhort, and it muſt be ſeized, for all depends upon it; and happily for the Owner Nature is not remiſs in marking it, if he be not negligent in taking her Inſtructions. The Time of flowering is the exact Time of this Period. This is a very viſible Notice, and let it be taken accordingly.

The Flax always flowers juſt when it has arrived at its full Stature; it never flowers regularly before, nor except by ſome Accident defers it longer. Therefore till it is in Flower the Fibres in the Stalk are green and weak; when it is in Bloom they are white and ſtrong; and when it loſes the Flower and is ripening the Seed, they become harſh and brown. Whiteneſs and Strength are the Qualities we require in theſe Fibres, therefore the Period of flowering is the exact Time whereat the Plant ſhould be gathered.

We ſee in all Herbs that the Stalks are weak and tender till they flower: they are firm and in their Perfection when the Plant is in flower, and they dry up and grow brittle when the Seed ripens. Flax follows the Courſe of other annual Plants, and muſt be therefore pulled when the Flower is juſt opened, in order to have it in the full Degree of Strength, Colour, and Perfection.

When the Pullers are ſent into a Field of Flax, they are to be ordered to be as expeditious as poſſible in their Work. The Flax roots very lightly, ſo that the leaſt Touch takes it up, and this is the Reaſon of the gathering it by Hand in that Manner. As they pull it up they muſt gather it into Handfuls, and tying theſe together they muſt be ſet up in the Field at Diſtances one from another. In this Condition they are to ſtand till they are thoroughly dry: the Sun and Air ſoon do this perfectly, and they grow firm but not harſh in the drying.

As

As ſoon as perfectly dry the Handfuls are to be houſed, and they are then ready either for Sale to the Manufacturers, or for the Uſe of the Owner if he will work them himſelf, by which he may be very well aſſured he will get the greateſt Profit.

CHAP. XXVII.

Of the working of Flax.

WHEN the Flax has been well dried after the pulling, the next Operation is what is called Rating of it; as to the houſing the Bundles, that is a Matter merely of Convenience. If every thing be prepared, and the Huſbandman manufacture it himſelf, he may take it directly from the Field to the Water; if otherwiſe it is houſed, to keep it out of the Way of Harm.

Rateing of Flax is ſteeping it in Water, in order to looſen its Bark or Rind. The thready Part of the Stalk is all that is to be uſed, and therefore the firſt Thing to be done is to ſeparate the Rind from it, that not being thready or any Way uſeful.

Experience ſhews that the beſt Manner of doing this is by ſoaking it in Water, and that is the Rateing of Flax: it is done thus. They lay the Bundles in a ſhallow Pond or Ditch, dug for that Purpoſe, putting ſome ſlight Weight upon them to keep them under the Water, and every other Day they are to be turned.

When they have lain thus ſix Days they are to be taken out, if the Bark be ſufficiently looſened. This is eaſily known by rubbing one of the Stalks from the Middle of the Bunch between the Fingers: if the Bark part eaſily they have been rated enough, if not they muſt lie a Day or two longer, but uſually, at that Seaſon of the Year, ſix Days are ſufficient, ſometimes it is done in five.

When taken out of the Water the Bundles are to be ſpread abroad and dried; and they will thus be prepared for the brakeing. This is the ſecond Operation they go through, in order to being prepared for Linnen. This is performed by a particular Inſtrument made for that Purpoſe, and called a Brake, it is notched at the End or throughout, according to the various Methods in different Places, and with this the thready Part is ſeparated from the Bark and looſened. The Method is to begin at the Root, and go all the Way up to the Top.

When the Flax has been thoroughly broke by the Brake, it hangs in Threads and ſcattered Pieces, and it is then ready for the third Operation, which is the ſwingling. This is a Kind of beating, and is to be performed with an edg'd Stick, called for that Reaſon a Swingle. This ſeparates the Fibres more, and it always lays them more regularly, and by this the Flax is prepared for the fourth Operation, which is the beating.

For this Purpoſe the ſwingled Flax is laid on a Block, and laboured with a Beetle, or it is put into a Trough, and beat with a Hammer, and this beating is continued till the whole Subſtance of it is made ſoft and pliable.

When the Flax has been ſufficiently beat it is fit to be hackled or combed. This is done ſomewhat in the Manner of combing of Wool, what are uſed in this Caſe for Flax being called Hackles.

It is to be worked thoroughly through theſe, one after another, till all the ſhort Stuff is got out; and all the long and fine Fibres are made ſmooth, and lie evenly together in Form of ſo many Threads; in this Condition it is fit to be ſpun.

This is the whole Proceſs in forming the Stalk of the Flax, gathered at a proper Degree of Maturity, into Thread, and thence into Linnen; the whole is very familiar, and can admit of no Miſunderſtanding. It were exceedingly to be wiſhed that the Plainneſs of the Practice, and the great Profits would lead more into the Work.

When any large Work of this Kind is carried on, there need be no grudging of the Expence of Implements; and where leſs there are various Ways of contriving to ſave Money. In ſome Parts of England all the Trouble and Charge of beating Flax by Hand is ſaved, by a particular Structure of their Corn Mills; they make the Axle-tree of the principal Wheel longer than uſual, and they place Pins in it, which by the Motion of the Mill raiſe large Hammers: theſe beat the Hemp in the Manner of the Hammers uſed in Fulling Mills. Many other Contrivances in this Way might eaſily be made, but the firſt Point is to get People into a Way of ſetting about the Culture of the Flax.

Thoſe who raiſe the Flax for the Stalk and Seed both, have a neceſſary Operation which we have not yet named, becauſe in this Practice we adviſe, all that is concerned is the Stalk only, the Seed being reſerved in Parcels kept for that Purpoſe. However, that no Information may be wanting for thoſe who raiſe Flax in their own Way, we ſhall add the Method of ſeparating the Seed before the Stalks are put to be watered.

This is called ripling, and it is thus done. The Flax being pulled when the Seed begins to be brown, for that is the Time according to this Practice; when the Bundles have ſtood up ſeven or eight Days, and are pretty well dried they are to paſs through the Ripple; this is a Kind of combing of the Stalks. The Ripples are made of Wood, and have their Teeth ſo cloſe, that when drawn over the Stalk they ſtick at the Heads or Seed Veſſels, and pull them off.

When this is done the Bundles are to be put into the Water, as has been directed already; and as to theſe Seeds not being yet altogether dry, they are to be laid by in an airy Room till Spring, when the whole is to be thraſhed in the common Way, to ſeparate the Seeds from the Huſks.

This Operation, in ſome Degree, prepares the Stalks for rating: but it is not neceſſary. According to our Advice no Regard is to be had to the Seed of that Flax that is raiſed for manufacturing; and therefore the whole Bundles, when they are moderately dried, are to be put into the Water, where the Leaves will fall off about the third Day, and ſometimes the Stalks will

will be ready for their firſt Dreſſing the Day but one afterwards, and ſometimes the very Day after.

The Time of taking them from the Water is one of the critical Points in the managing and manufacturing of Flax, it muſt therefore be watched accordingly.

When the Bark will part, and the Threads ſeparate, it is fit for taking out, and that Time ſhould not be let ſlip.

If this happen the third Day there is no Occaſion for any more rating, and if it be not in this Condition on the ſeventh, it muſt lie longer. We have given the common full Time it is in preparing in this Operation, but the Condition of the Flax is to guide the Workman, not any particular Number of Days of lying.

CHAP. XXVIII.

Of Hemp.

AFTER the Conſideration of Flax we are naturally led to that of Hemp, theſe two Species being raiſed for the ſame Purpoſes of Cloth, though the Flax be the finer. The Culture of the two Plants agrees in many Reſpects, though in their Form and Nature, excepting that ſingle Article the Threadineſs of the Stalk, they differ as much as it is poſſible for two Plants to do one from another.

Hemp is a large, tall, buſhy Plant, of a very rough Aſpect and irregular Growth, but ſufficiently upright and firm.

We have explained to the Huſbandman, under the two former Articles of Hops and Flax, the Conſtruction of Plants in Reſpect of their Fructification or Production of the Seed. We have ſhewn that there is a Male Duſt which is to impregnate a Female Embrio, or young Rudiment of the Fruit. In Flax, as in moſt Plants, we have ſhewn that this Male Duſt, and the Female Embrio are lodged in the Boſom of the ſame Flower; but in Hops the Male Duſt grows in a Kind of little Flowers on ſome Plants, and the Female Embrio or young Rudiment of the Fruit on others. This is the Caſe with Hemp, as well as with the Hop; and from hence has ariſen a Diſtinction in this Kind into Sexes.

The Huſbandman obſerving that from the ſame Quantity of Seed there roſe two Kinds of Plant, though alike in Leaves and Stalk, the one bearing little duſty Flowers and no Seeds, and the other producing Seeds without any obvious Flowers, called theſe two Kinds by the Names of Male and Female Hemp.

This was not improper, but they erred ſtrangely in applying the two Names, for they called thoſe Plants which produced Seeds the Male, and the others the Female.

This was ſo contrary to Nature, that being in all Species the Female which bears the Embrio or young, that the Names have been changed; and are now given to thoſe Plants to which they properly belong, that with only Flowers of this duſty Kind being called Male Hemp, and that which has Seeds Female.

After this general Account of Hemp we may proceed to the Deſcription in common to both, for excepting the Flowers and Seeds, the Difference between one and the other is very ſmall, and may be named occaſionally.

Hemp is an Annual Plant. The Root is long, ſlender, divided into Branches, and full of Fibres. The Stalk is thick, upright, ridged, of a green Colour, and grows ſix or ſeven Foot high. The Leaves are very numerous, and are divided in the Manner of Fingers, or in other Words five ſeparate Leaves grow upon each Foot-ſtalk, ſpreading like Fingers, they are of a dead green Colour, rough to the Touch, and notched at the Edges: Tho' five is the common Number of theſe Diviſions, it is not without Variation, for ſome of them have ſix or ſeven.

In this both Male and Female agree, but the Difference between them is, that the Male is the lighter and more delicate Plant. The Stalk is ſmall, and it has fewer Branches; and it is tenderer and more hollow.

On the Tops of this Kind grow the duſty Flowers, which are of a whitiſh Yellow with a Tinge of Green, little and inconſiderable. The other or Female Hemp is more robuſt, the Stalk thicker and more branched, and inſtead of theſe duſty Flowers it bears the Seed.

The Male Hemp is by ſome diſtinguiſhed by the Name of Summer Hemp, and the Female by that of Winter Hemp; becauſe the Male comes to its Ripeneſs a Month or five Weeks ſooner than the other, and it yields the fineſt Thread. The Structure of the ſeveral Flowers and Fruit are curious in this Plant, and very worthy Obſervation.

In the Male the Flower is compoſed of five little hollow Leaves, pointed at the Ends and growing together at the Bottom, in the which ſtand five very ſmall Threads, with each an oblong Button at its Top, of a ſquare Figure.

In the Female there is a green Huſk of an oblong pointed Shape, which ſplits open on one Side, and at firſt contains the Rudiments of the Seed, and afterwards the Seed itſelf, for it does not fall off as theſe Parts uſually do. In this ſtands the Rudiment which is very ſmall, and has two long Points riſing from it, ſharp at the Ends; the Seed follows, and continues ſhut up cloſely in the Huſk.

This is the Courſe of Nature in ripening the Seed of this Plant.

Hemp was known to the antient Greeks and Romans. It is a Native of the warmer Climates: but where it grows wild in Abundance, they cultivate it not the leſs in Fields for Uſe; for the Stalk never has its Perfection in the wild State. It no where grows ſo luxuriant wild as in the East Indies, but even there they raiſe it for Uſe by a proper Culture.

There is properly but one Kind of Hemp. We have mentioned already the Difference of Male and Female Hemp, but they both ariſe from the ſame Seed, therefore they are properly of the ſame Kind, though they differ by Accidents. There is an Account in Authors of a Plant called Virginian Hemp, which is large, and has Leaves unlike ours, they being ſingle, not fingered, neither does it produce its Seed like it, though the Courſe

of Nature in it has ſome Reſemblance. This grows in the Salt Meadows of Virginia, and is called by ſome Acidna. There are alſo ſeveral Kinds of a wild English Plant called Baſtard Hemp; but this is properly a Sort of dead Nettle, and ſhould be called the dead Nettle with Leaves, like the ſingle Leaves of Hemp, diſtinguiſhing the Kinds afterwards, according to their Differences.

Theſe we have thought needful to name, that the enterprizing Huſbandman might not be led to ſuppoſe them ſo many Kinds of Hemp, or to cultivate them as ſuch. This would be purſuing Curioſity at the Expence of Uſe, there are only the Male and Female Hemp he is to regard, and theſe he will always have when he ſows Hemp at all, becauſe they both riſe from the ſame Seed. We have already informed him concerning their Diſtinctions and Uſe.

CHAP. XXIX.

Of the proper Land for Hemp.

THE Culture of Hemp is one of thoſe neglected Articles within the Province of the Huſbandman, by which he who will engage earneſtly and judiciouſly in it, will not fail to make very conſiderable Advantage. We ſhall in this, and the ſucceeding Chapters, lay before him ſuch Directions for the whole Management of his Crop, that he ſhall not be left to ſeek in any the leaſt Point; and ſhall be happy if by ſpiriting up the Induſtrious and Ingenious, we can promote a Thing that will be not only uſeful to themſelves, but to their Country. The Importation of Hemp in various Forms, is a Reproach upon the English Huſbandry, for we are able to raiſe it as well as any of thoſe from whom we receive it.

In the undertaking this Article of Huſbandry, the firſt Thing to be conſidered is the Soil. For there is no Growth whatſoever that ſo perfectly depends upon the Nature of the Land for its Succeſs.

We have Ground enough in England that is proper for it; indeed there is no where ſo much of a right Kind, but let the Huſbandman take Care he does not ſow it upon a wrong.

Hemp requires a deep, rich, light, and dry Soil. In England we have more and finer Loams than in any Country whatever, and theſe are the Kinds of Land that beſt anſwer to this Deſcription. One of our dark duſky Loams in which there is a good deal of Sand, and a large Quantity of pure Mould, will anſwer beyond any other Soil whatever; we have a great deal of this Land in Northamptonshire, Lincolnshire, and Buckinghamshire, and I have obſerved that it there runs very deep, often two Foot and a half or three Foot, with a good open Loam at the Bottom. This is the beſt of all Grounds for raiſing Hemp. It is a Soil that will bear any Crop; but the Farmer will not find any that will bring him a greater Advantage on this Land.

There are Soils that are particularly improper, as well as ſuch as are fitted for this Growth. The moſt wrong of all are cold Clays: on theſe Hemp can never thrive; it is a Native of the Eaſt, where the Soils are light and dry, it is therefore againſt Nature to force it here, to live in a cold, tough, and wet Clay.

The Farmers are aware of this, and therefore I cannot ſay I have ſeen Hemp any where ſo planted; but the other Soil, on which it ſucceeds poorly, is that on which it is too often ſown, this is the deep black Mould that lies in low Paſtures, and is always wet. This is what we have called, in our firſt Book, the rotten mooriſh Soil. The Depth and Richneſs of this would agree very well with Hemp, but it is always too moiſt and too cold.

A deep Earth and Freedom for the Roots to paſs every Way, is one of the Requiſites for Hemp; but Warmth is the other, and this latter is ſo eſſential, that it will grow better in a poor Land that is warm, provided it be deep, than in a very rich one that is too cold.

It is for this Reaſon Sand is ſo eſſential an Article in the Soil for Hemp. I have made it an Obſervation, that I never ſaw this Plant thrive any where, where there was not Sand in ſome conſiderable Quantity in the Ground. I am aware of an Objection that will be made to this Aſſertion, by thoſe who have ſeen Hemp cultivated in the lower Parts of Northamptonshire, but I have ſeen it there, and have anſwered ſo natural, yet groundleſs, an Objection on the Spot.

The Land on which they raiſe Hemp in this Part of England, is a deep black Mould, which has been of the moory Kind; but by the perfect draining of the adjacent Fens is now left altogether dry and crumbly.

Hemp would not have grown here to any Profit, while the Land was wet, but it ſucceeds very well in its preſent State. I have often talked with the Farmers who raiſe it here, and they have told me there was no Sand in the Ground; to convince them I have only waited for a Shower of Rain, after which the firſt Eye that is caſt upon the Ground ſhews it in Abundance.

The Truth is, this is the richeſt Loam in the World, there is a little clayey Matter which holds it very well together, and ſerves to detain Wet enough to keep it always moiſt, and yet not enough to chill it: and there is a conſiderable Quantity of a middling brown Sand: this warms and opens it excellently, but the Body of the Soil being a fine black Mould, that covers both the clayey Particles and the Grains of Sand, till waſhed off by Rains.

This is a particular Soil, but it is not ſingular in that Place; I have ſeen it in Lincolnshire, Warwickshire, and Leicestershire, wherever it is the Farmer may be aſſured, if he will ſow Hemp upon it, he will have a very great Return.

I have ſeen the Experiment of ſowing Hemp on gravelly and ſtony Lands, and as to the Succeſs, that has depended altogether upon the Condition of the Soil in Depth, and the Degree of ſtonyneſs; if it be a deep loamy Earth, with a moderate Quantity of Gravel or Limeſtone Frag-

ments

ments on the Surface, nothing does better, but if it be gravelly to the Bottom, or the Stones be too large, it will not ſucceed.

CHAP. XXX.

Of preparing Land for Hemp.

A Field may be put in order for Hemp, either by breaking it up freſh, or by manuring it after other Crops, but the former is the better Way.

In NORTHAMPTONSHIRE they commonly break up Paſture Ground, when they have Opportunities for it; and in ſome of the Counties where they have got into the Method of raiſing the artificial Graſſes, they break up an old Lay of one of them, and it always anſwers very well. Once I ſaw a Piece of Woodland firſt ſown with Hemp, after the ſtubbing up the Roots, and moderately ſpeaking, the Crop was twice as large as I ever ſaw it on any other Piece of Ground: the Soil was very proper, deep, and loamy, and it had lain in Wood many Years.

Whatever Ground be choſen it will require to be very well dreſſed, to prepare for this Growth: not that Dung is ſo proper, for Hemp does not ſucceed well upon it; but a right Degree of Tillage.

This recommends the Horſehoeing Huſbandry, as for Flax ſo alſo for Hemp, before all others, becauſe that gives the neceſſary Dreſſings by Tillage, and omits either altogether or in great Part the Uſe of Dung.

When any Manure is uſed to a Field deſigned for Hemp, it will be better to chuſe ſome other Kind of the ſeveral that we have mentioned in our ſecond Book, and not Dung, ſince Hemp does not affect that. It will be better to improve the Soil by the laſting, than by theſe temporary Additions.

From what has been ſaid it will be eaſily ſeen, that Land which has been bearing other Crops is not ſo proper for Hemp, as ſuch as is freſh. Hemp requires a great deal of Nouriſhment; and theſe Fields are exhauſted by the Crops they have borne: then there is no Way in the common Practice to recruit theſe but by Dung, and that Hemp diſlikes. Therefore the other or freſh Lands are better: but though the beſt they are not the only ones that will do. I write in theſe Things from Experience and Obſervation. I have told the Farmer what I have ſeen, I ſhall add what I have tried. I have made a Piece of Ground that had borne its third Crop in the uſual Way, yield a very good Produce of Hemp by only good Tillage, without any Addition of Manure whatſoever. Therefore it is ſpeaking from Experience as well as Reaſon, to recommend the Horſehoeing Huſbandry for Hemp. Let the Farmer take Care that his Soil be proper, and he may raiſe this valuable Commodity upon it at any Time, or in any Condition, only by a ſufficient Tillage.

This Aſſertion is founded upon Fact, and that cannot miſlead any; and it is the greateſt Proof I know of the Truth of thoſe Principles on which the Practice of Horſehoeing has been eſtabliſhed. Hemp requires a great deal of Nouriſhment, yet it will thrive very well upon Land ſo exhauſted by its third Crop, that it would have yielded nothing elſe to any Profit without a Refreſhment of Manure, there being no Manure at all added for the Hemp, but the whole being done by Tillage only.

This is a Proof that Tillage alone does prepare the Earth to yield Nouriſhment to Plants, for the Hemp thriving ſhews that it has Nouriſhment in Abundance. And there has been, in this Inſtance, nothing but the Tillage to give it.

As to the Practical Directions for a Choice of Land, they may be collected from what we have laid down already. We ſhew here that any Condition of the Land will be made to do, with proper Management; but the beſt is ſuch as has been covered with Wood; the next beſt is ſuch as is freſh broke up, whether from natural or artificial Graſſes: the leaſt favourable of all is that which has been exhauſted by other Crops; but this may be made to anſwer.

Upon this Diſtinction depends the Management of the Land, which is the proper Buſineſs of this Chapter: but could not be thoroughly underſtood without firſt ſettling theſe Diſtinctions. We would have the Farmer in all Caſes know not only what he is to do, but why he is to do it.

Thus in the preſent Caſe, if the Land on which he intends to raiſe Hemp be new broke up, whether from Wood or from natural or artificial Graſſes, all he has to do is to break it ſufficiently fine, and expoſe it a little to the Sun and Air; and then going over it once again to level it, and then get in his Seed; but if it be a Field that has borne other Crops, and is exhauſted, he is to refreſh it, not by Dung but by ſubſtantial Manures according to its Kind, as with Mud, Sand, or the like; and to break and divide it by repeated Tillage, in order to enrich it. In this Caſe, the oftener he goes over the Ground the better, and the more Variety of Inſtruments he uſes the richer he will make it. Let him turn it up deep with a proper Plow, and tear it to Pieces afterwards with a Harrow. Then, in a dry Seaſon, let him draw a heavy Roller over it, to cruſh the Clods; and when he has done this harrow it again, to break thoroughly to Pieces what the Roller only bruiſed.

After this let him give it Reſt for ſome time, that the Sun and Air may penetrate it well, and then begin by plowing again.

Let this Practice be obſerved throughout the Winter, and in Spring let him lay it level and even for his Seed.

CHAP. XXXI.

Of the ſowing of Hemp.

THE Land we underſtand now to be well prepared, whether rich in its own Nature or made ſo by Tillage. We ſuppoſe the Winter Dreſſings to be paſt, and are now got into Spring, that is the Seaſon for ſowing this valuable Crop.

Firſt let the Farmer take Care that he get good

good Seed: if he commit any Error in this Reſpect, all the reſt of his Labour will be fruitleſs. Let him chuſe ſuch Seed as is freſh, firm, and bright; and then try it by rubbing it well between his Hands; if it bear this without breaking, and look the finer and cleaner for it 'tis good, but if it appear duſty, and in Part broken by this it is old and damaged.

Good Seed being thus choſen, the Quantity is to be determined, according to the Method propoſed for raiſing it. If by the common Huſbandry three Buſhels are to be allowed to every Acre: if the Drill and Horſehoeing be followed, which is much beſt, a Buſhel and half of Seed to every Acre is ſufficient.

The Seed being ready and the Ground dreſſed for bearing the Crop, the laſt Operation performed upon it muſt be the preparing it for the Seed; and this, whichever Method of Huſbandry is choſen, muſt be very carefully done.

If the common Practice be followed, the Farmer muſt go over the Ground with the niceſt Care. The firſt Week in April is the right Time for ſowing Hemp, therefore let him begin his laſt Dreſſing accordingly. If the Seaſon be unfavourable, the ſowing may be deferred a Week, ten Days, or even a Fortnight without Damage, but 'tis beſt when it can be done at the Time juſt named.

When the Farmer gives the Land this laſt Dreſſing, he muſt make it fine and level as the Border of a Garden; Hemp Seed is tender, it will not grow unleſs laid in very regularly. It requires but a ſlight Covering, and if it be laid in deeper it will never come up. If any Clods be left in the Ground they will fall over ſome of the Seeds, and ſuch will be ſure to periſh. I have ſeen the bad Effects of Careleſſneſs in this Article, and therefore caution the Farmer the more ſtrictly; he may depend upon this, that in the common Way of ſowing not a third of his Plants would come up; and one half of thoſe that do will riſe irregularly, and getting bad Habits by twiſting in their firſt Shooting, will never come to any thing conſiderable afterwards.

When the Land is of a ſufficient Fineneſs let a careful Seedſman go over it, with the juſt named Proportion of Seed to every Acre, and let him ſpread it regularly over the whole Ground, by ſingle Caſt, as evenly and equally as he can.

As ſoon as this is done let the Field be harrowed over very lightly, and then left to Nature: only with this Caution, that it be well defended from Birds.

There is no Seed of which the generality of ſmall Birds are ſo fond as Hemp Seed: it is a large and conſpicuous Seed, ſo that it attracts their Eye, and it is to be ſlightly covered, ſo that they can eaſily get at it: therefore Boys muſt be ſet to watch, and all imaginable Care taken of it for ſeveral Days after ſowing, otherwiſe the Farmer, with all his former Cautions, will have but a poor Account of it.

This is the Method of ſowing Hemp in the common Way of Huſbandry; and to what has been laid down already we have only one Caution to add, which is, that the Farmer who expects a good Crop do not follow the Practice of thoſe who do nothing to their Land till they are juſt going to ſow it. There are thoſe who content themſelves with giving it one plowing in Spring for Hemp, and no more; but by what I have ſeen they content themſelves alſo with a poor Harveſt. Hemp in its Nature requires a Land better dreſſed than almoſt any other Seed.

We have given the Method of raiſing Hemp according to the common Practice, we are to name the Way of doing it in the Horſehoeing Method, which we have before obſerved is vaſtly preferable. To this Purpoſe the Preparation of the Ground muſt be the ſame, as in the other Method, and the Seed is to be planted in double Rows, with ten Inch Partitions, and with Intervals juſt broad enough for the Paſſage of the Hoe Plow.

We have given Directions at large upon the Manner of ſowing in this Method of Huſbandry, therefore need not repeat thoſe general Inſtructions under every particular Article; only let the Farmer obſerve, that Hemp Seed muſt be planted very ſhallow; and therefore ſet his Drill accordingly.

Hemp is a large Plant, therefore it muſt not be planted in treble Rows, for the middle one wanting Air and Space for its ſmall Roots, would come to nothing. It ſucceeds very well in a ſingle Row; but Experience ſhews, that in the double, with this Interval, the Plants grow as well, and the Profit is much larger. This is the Method of cultivating Hemp to the greateſt Advantage, and with the greateſt Certainty of Succeſs.

CHAP. XXXII.

Of the ordering Hemp in its Growth.

IT is the Advantage of the Horſehoeing Huſbandry, that it ſupplies Plants continually with freſh Quantities of Nouriſhment during their Growth. This is not more neceſſary for any thing than for Hemp, for the filling of the Stalk depends very much upon it. 'Tis for this Reaſon that we have ſo particularly recommended the new Huſbandry for this Species. A Plant raiſed this Way will be often worth four in the common Method.

In that Practice the Hemp is to be left altogether to itſelf, as ſoon as it is well out of the Ground. The Attendance is only required till the Body of the Seed is waſted. Birds will not meddle with it afterwards, and as to Weeds they cannot live among it. 'Tis a quick Grower, and a very ſtrong Plant; and in the Way of ſowing by the common Method, the Shoots will riſe ſo near one another, that they will have enough to do to live well themſelves, till they begin to pierce with their Roots to ſome Depth; and neither then nor afterwards, will they ſuffer any thing elſe to live among them.

Hemp is ſo far from being in Danger from theſe, that it is the beſt Thing that can be ſown for preventing them for the future. Nothing clears a Land ſo thoroughly from Weeds as a Crop of Hemp; but then it exhauſts the Land ſo thoroughly, that it leaves it fit for little elſe without a great deal of Preparation.

We

We have ſaid the two great Advantages of the Horſehoeing Huſbandry, are the deſtroying Weeds and furniſhing the Crop with Nouriſhment while growing. For the firſt Purpoſe Hemp we ſee does not need its Aſſiſtance; but nothing requires it more for the latter. If Hemp ſatisfies the Farmer in the common Way; it will enrich him in this, for every Plant will ſpeak for itſelf in the Praiſe of this Method of Culture.

When the Seed is let in by the Drill the Danger is not ſo great from Birds and other Vermin, as when ſcattered in the common Way, becauſe though covered but at a ſmall Depth, ſtill it is all covered; but this, though ſome Help is not a ſufficient Security, one Seed that ſhall chance to lie naked will tempt theſe Devourers; therefore it is to be watched in the ſame Manner as when let in in the common Way of ſowing. The Time of the Birds feeding upon the Seeds is principally before Sunriſe, therefore the Ground muſt be carefully watched from Peep of Day: after this they are leſs ravenous, till toward Evening, when they feed again, till within half an Hour of Sunſet.

We don't mean by this that they need not be watched at other Times, but theſe are the Hours wherein they require the moſt ſtrict Care.

When the Hemp has got four or five Inches Height in the Shoot, the Weeds will begin to fill the Intervals; and ſome, though not many, will riſe in the Partitions between the two Rows. Let the Farmer ſend in careful Labourers with Hand Hoes, to cut down thoſe that have riſen in the Partitions; once doing this will be ſufficient, for the Hemp gathering Strength will not permit them to get up any more.

Theſe Hoers ſhould be ordered alſo to pull up here and there a Plant of the Hemp, where they have riſen too thick: but this is an Article of his Employment in which he muſt be ſparing, for the working of the Intervals between, will render the Ground capable of ſupporting the two Rows of Hemp, with the Plants cloſer than can be well imagined.

When the Weeds are cut down by Hand in the Partitions, let the Horſe Hoe be brought into the Intervals, and with this let all the Ground between the Pairs of Rows be turned up deep, and broke very fine. The Weeds will be deſtroyed by this, which were too far off the Plants of Hemp to be ſtarved by them; and the whole Soil will be made fit to receive the Roots of the Hemp, and filled with Nouriſhment to ſupport them.

The Effect of the Horſehoeing is in no Caſe ſeen more perfectly or plainly, than this Inſtance. The Fibres of the Roots of Hemp, even in the moſt favourable Soil, do not naturally ſpread, for they lie in Cluſters about the Baſe of the Stalk, their Number anſwering for their Shortneſs. But in this Way of Horſehoeing the Fibres of the two oppoſite Rows will meet acroſs a five Foot Interval very viſibly, and fill all the Space between; this is plain to the Eye in examining the Roots, and the flouriſhing State of the Plant confirms it.

The Horſehoeing muſt be repeated as often as the Weeds get up in theſe large Intervals; for no more, after the firſt, will riſe in the Partitions; and in this Manner the Ground will be every now and then cleared and enriched, till the Time of pulling the Crop. It will be filled with Nouriſhment by the Work, and all that Nouriſhment will come to the Crop.

CHAP. XXXIII.

Of the pulling of Hemp.

WE have brought our Hemp from the Seed Time to its full Maturity. The Summer has been left for its Growth, and we ſuppoſe we are now arrived at Lammas Time, which is the Seaſon of the firſt Hemp Harveſt. We ſay the firſt, for there are two Gatherings of this Plant in every Ground: the Male and Female Hemp, which always riſe together from the ſame Seed, differing, as we have obſerved, in the Time of ripening.

This makes a very particular Article in the Management of Hemp, and a particular Caution is to be given the Huſbandman not accuſtomed to this Crop, about it.

We have mentioned the Seaſon of the Male Hemp, which is called alſo the Summer Hemp, and by ſome fimble Hemp, ripening. At this Time let him keep his Eye upon the Field, and obſerve when he ſees the Leaves beginning to hang and turn yellow. He will ſee this when once it has begun, ſpread quickly through the Field, but only upon the Male Plants. About the Time of the Leaves drooping and growing yellow, the Stalks turn whitiſh, and this is the Signal for gathering, no farther Care is needful. This Kind bears no Seed, ſo that there is no ſecond Conſideration as there is in the other.

When the Male Hemp has got into this Condition, the Pullers are to be ſent into the Field to get it up. Hemp is gathered like Flax, by tearing up by the Roots, and therefore the gathering of theſe is called pulling. But here there is a great Difficulty. The Flax is eaſily enough pulled up, becauſe it is all to be pulled up; but in the Hemp it is only a Part: and it is not eaſy to do this without damaging the Remainder, a careleſs Conduct in the gathering this Part of the Crop might eaſily ſpoil the other.

When Hemp has been ſown in the common Method, all the Owner can do is to caution his Pullers that they do not trample down, break, or otherwiſe injure the Female Hemp that is left ſtanding; but with his beſt Inſtructions, and their beſt Care, there never fails to be a great deal of Miſchief done. Therefore in this Reſpect, the raiſing Hemp by the Drill and Horſehoeing Huſbandry, in the Method of double Rows as we have adviſed, has a vaſt Advantage. In this Way the Intervals between two and two Rows are ſo wide, that the Pullers can eaſily and freely get in between them; they can take up the Male Hemp without the leaſt Damage to the Female, and they have Room to manage it and get it up into Bundles. All this which is ſo very eaſy in the new Way of raiſing the Crop, is ſubject to the greateſt Difficulty and Diſadvantage in the old.

The firſt Pulling being thus over, the remainder

mainder of the Growth is to ſtand till MICHAELMAS. It thrives the better and the faſter a great deal in either Way of the managing, becauſe of being thus thinned; and the Time of gathering it coming in late, after the other Harveſt Work is over, is very happy for an induſtrious Poor, in the Places where it is propagated.

The gathering of the Male and Female Hemp is to be done in the ſame Manner, except that there is to be a Difference in the making up of the Bundles. Each Kind is to be bundled up as the Flax, but the Male Hemp is to be gathered into ſmall, and the other into large ones. The Male Hemp ſhould be gathered up into ſuch Bundles as may be graſped with both Hands, but the Female Hemp is uſually got up into ſuch as are a Yard round. This is all the Difference in reſpect of gathering.

CHAP. XXXIV.

Of the drying of Hemp.

IN the Hemp of the firſt gathering nothing is to be minded but the drying it in a proper Manner, to fit it for farther working; but in the Female Regard is to be had to the Seed.

The Time of making the ſecond gathering is, for this Reaſon, determined by the ripening of the Seed on the Plants; and when gathered and bundled, theſe Bundles are to be ſet up in the Sun four or five Days, and then ſtacked up, that at a proper Time the Seed may be thraſhed out before they are fitted for farther Manufacture. It is the common Practice to raiſe this Hemp in Stacks, in ſome ſheltered Part of the Field, but as the Beginning of OCTOBER is uſually a dripping Seaſon it is better to houſe it. A little Wet does it no Harm as to the main Article of the Stalk, but it may very eaſily get Damage in Reſpect of the Seed; and as the houſing it is eaſy 'tis much better to do it; the Owner then takeing his own Time to thraſh it.

The Caution we have given the Farmer about ordering Care to be taken that the Hemp that is to remain for the ſecond gathering, be not hurt in the firſt, will be eaſily ſeen to be worth his moſt ſerious Conſideration, when he comes to thraſhing his Female Hemp. From the Produce of an Acre of good Land he will get three Quarter of Seed, if he have followed the common Huſbandry in raiſing it; but if he have done it in the Horſehoeing Manner he will have four or five Quarters, ſometimes more; the Plants in that Way branching out more, and bearing a much larger Quantity of Seed, and alſo ripening it better.

This, which is but an additional Conſideration, ſets the Female Hemp a great deal above the Male in Value, and at the ſame Time the Stalk of Hemp itſelf is much more valuable in the Female than in the Male.

CHAP. XXXV.

Of the watering of Hemp.

WHEN the Male Hemp is gathered nothing is to be done but drying it a little, before it is carried to the Water; to this Purpoſe the common Practice is to bundle it up at once, as it is pulled, and ſet the Bundles up on End till the Moiſture is ſomewhat evaporated.

This is all that can be conveniently done in the common Way of Huſbandry, becauſe there is no Ground for ſpreading it; but in the Horſehoeing Method, as there is Space between two and two of the Rows, it is beſt to throw it upon the Ground as it is pulled, and there let it lye a Day and Night; and after that to gather it up into Bundles.

This may be practiſed for the Female Hemp, in the common Way of Huſbandry. It is not an Article of any great Conſequence, but it is beſt to do it in both.

The Male Hemp, as ſoon as it is a little dried from the gathering, and the Female, after the thraſhing, are to be carried to the Water in their proper ſized Bundles. For this Purpoſe a large ſhallow Pond is beſt, and it ſhould have a firm Bottom: running Water would anſwer beſt, but it is not permitted any where to uſe it, for the Hemp infects it, deſtroys the Fiſh, and ſpoils every thing that is done with it.

Let the Farmer therefore who is raiſing Hemp take Care to have a Pond of proper Depth and Dimenſions ready, according to the Quantity of his Hemp.

He is to prepare for the Hemp by driving in half a dozen Stakes in a ſquare Form, very firmly into the Bottom. There the Hemp is to be brought and laid in, keeping it under Water; and the ſmall Ends of the Bundles are to be placed interchangeably, the thick Ends of one Bundle being laid one Way, and the thick Ends of the next another, and ſo with the whole Parcel.

In this Manner the Bundles are to be laid in one upon another, and the Water is to cover them all.

When the Bundles are all in there are to be Over-layers, as they call them, of Wood bound to the Stakes, to preſs them down, and keep them not only under the Water, but fixed from ſtirring about. Some cover the Square within the Stakes entirely with Over-layers of Wood; others only cover the Edges with theſe, throwing great Stones or other heavy Rubbiſh, to keep all under Water. Whichever Way the Hemp is kept conſtantly under, 'tis all one.

When it has lain thus five Days, one of the upper Bundles is to be taken out and waſhed in another Part of the Pond. In this waſhing the Farmer is to obſerve whether the Leaf comes freely off, for if it does the Hemp is watered enough; if not it muſt lie longer.

When it is watered enough the Bundles are to be taken out one by one; and waſhed in other Parts of the Pond, that all the Leaves may be got off, and any Filth or other Matter that may by Accident be got among them, may

be discharged. This done the Business for watering and washing is over, the clean Stalks are to be set up an End, that the Wet may drain from them. When they are thus pretty well drained from the Water that hung about them, they are to be carried to some Place where they can be set up against a Wall or Pales, exposed to the South Sun, that they may thoroughly dry. This prepares it for the next Operation.

CHAP. XXXVI.

Of the brakeing of Hemp.

WHEN the Hemp has been cleared from Leaves and Filth, and dried from the washing, it is ready for the Brake. This is a wooden Instrument made with an Edge, and in all Respects like that used for Flax before described, but that it is larger and stronger. This is the Case with all the Instruments used in dressing of Hemp, they are the same in their Nature as well as Uses, with those employed in the dressing of Flax; but as this is a coarser Matter, they are larger, coarser, and stronger.

The Effect of this Dressing is, that the Bark or Rind of the Hemp is separated from the stringy Part of the Stalk, and that is broke and prepared for farther manufacturing.

The thorough drying of the Hemp is altogether necessary to the doing of this well, for otherwise the Bark will not separate, nor the Threads come to Pieces; and the Dryness of the Weather is a great Advantage in the same Respect, wherefore this should never be set about but in a favourable Time.

If the Season have been dripping, and the Hemp could not be got thoroughly dry by the Method already directed, it must be done by the Assistance of Fire: but there is great Caution necessary in this Respect, the Hemp so easily takes Fire in the drying. So many Accidents of this Kind have happened, in Places where Hemp dressing is carried on, that every one ought to be vastly upon his Guard who ventures on it; and if possible the Hemp should be dried without having Recourse to this dangerous Expedient.

In some Places they raise a Kind of Frame for this Purpose, which answers very well. They drive Stakes into the Ground at proper Distances, and lay Hurdles over them at five Feet from the Ground: they then spread the Hemp thin upon these Hurdles, and make a small Fire underneath. This requires good watching, but as a little Heat does for the Hemp it may be conducted without Danger. The Expence is trifling and it makes it work much the easier.

The Method of brakeing is the same in Hemp as in Flax, and the Purpose is also the same, the preparing it for farther dividing. It must be begun at the Root End, and so broke up to the Top; and the Person who brakes it must look into his Work at Times; the Design of brakeing it is, that the stringy Part of the Stalk may be all thoroughly crushed and loosened, when this is done, and it hangs in Shivers, it is enough; if otherwise it is to be broke more. Let not this be slighted: the whole Management of Hemp is very easy, but it must be conducted with Care; for a Mistake in this Respect can never be mended afterwards, without the greatest Difficulty, and often not without a great deal of Waste and Loss.

CHAP. XXXVII.

Of the dressing of Hemp.

IT would be natural to count the brakeing among the other Articles, in the manufactureing of Hemp under the common Head of dressing; but Custom establishes it otherwise, and we follow the usual Manner of speaking.

The brakeing of the Hemp being over, the next Operation is the swingling. As to the Article of brakeing, some perform it at once, which is the better Way, others go over it twice, this takes up Time, and with good Management is not needful. When the Hemp goes through this Operation twice the Brakes are of two Kinds, one coarser the other finer, and it is first broke in the one then in the other; but if a Brake of a middling Degree of Fineness be carefully used, once does it, and it will be fit for the Swingle without any more Trouble.

The swingling of Hemp, which is the first dressing after the Brake, is performed by two Instruments, a Block and a Dagger.

The Block is made of a single Deal raised four Foot above the Floor, and supported strongly to keep it steady; the Dagger is a wooden one, of the Form of a broad large Dagger, with a blunt Edge.

With this Dagger the Hemp is worked upon the Block, opening and beating it till all the knotty Pieces and Shivers are entirely broke, and the whole is perfectly smooth and even.

The Parcel of Hemp brought to the Brake together, is called a Strike: this they also bring to the Swingle together, and when they have sufficiently wrought it they strike a Fold or Twist in the Middle, which is the thickest Part, and so lay it by, proceeding with the rest till the whole Parcel is done.

This swingling is a very useful Operation, and it must be done carefully: the more so because it prepares the Commodity at once for the Market, if the Owner chuses to part with it in that Condition. For this Purpose he should observe, that there are two Things to be done in the swingling, the one is the breaking out the Lumps and Shivers, and the other is the softening of the thready Part, which is very well effected by the swingling, provided that be done carefully.

If the Owner chuse to part with his Hemp in the State just named, he has no more to do but carry it to Market; but he may more profitably prepare it farther. Every succeeding Operation is a getting it more and more ready for Cloth. The next to what we have already named, is a second swingling. This is done exactly in the same Manner as the first, and this works it still finer. The first swingling beat away the Lumps and softened the Teares, this second di-

vides

vides the Threads finer, lays them ſmoother, and prepares it for heckling.

When the ſecond ſwingling is over, the Strikes are to be divided into Dozens and half Dozens, and ſo made up into great thick Rolls. Theſe are to be ſpitted upon long Sticks, and hung up in the Chimney, or in the Way of ſome other gentle Warmth. They muſt be dried in this Manner till there does not remain the leaſt Damp or Moiſture in them; and they are then fit for beating. This is to be done in a deep and ſtrong Trough, or upon a Block hollowed at the Top, and the Beetles muſt be large and heavy. By this Operation all the Threads are rendered fine, clean and tough.

When this is done the Stakes are to be divided, and all examined, to ſee if the whole be beaten enough; frequently ſome are not, and theſe muſt be beaten again.

When the Hemp has been thus twice ſwingled, carefully dried, and well beaten, it is to be brought to the Heckle. But this firſt Heckle muſt be coarſe, and with very open Teeth.

From this heckling there will come ſome coarſe Parts, which neither the ſwingling ſeparated nor the beating ſubdued, theſe are to be laid aſide, and the Hemp that has gone through this firſt coarſe Heckle is then to be worked in one that is finer. This prepares it for working into Cloth in the uſual Way: but when it is deſigned for Linnen of particular Fineneſs, there is ſome Difference to be made in the Management; and this may be worth the Farmer's Notice, whether he intend to work it into Cloth at Home, or deſign it only for Sale in the Strike or heckled State.

Two Dryings are very convenient on this Occaſion, that is, when it has been dried and beat, and once heckled, it is to be rolled up and dried over again, and the beating and heckling repeated in the ſame Manner, and after this the Heckles deſigned for Flax are to be uſed inſtead of thoſe for Hemp; theſe being coarſer and not ſo fit for the fine Work, even in Hemp, as thoſe intended for Flax.

This is the Management and Preparation of Hemp, from the ſowing the Seed to preparing it for ſpinning. The Owner may ſell it in the coarſer or finer Condition, but he will find it moſt profitable to continue the Dreſſing, in the Manner we have directed, to the ſpinning.

CHAP. XXXVIII.

Of the managing the Hurds.

WE have mentioned occaſionally more than once, the ſeparating the coarſer Part of the Hemp in dreſſing and rendering it finer. This coarſe and knotty Part thus ſeparated, is called the Hurds, it is not to be waſted; but being laid aſide in the dreſſing of the other, is afterwards to be managed by itſelf.

To be properly underſtood on this Head we muſt refer to ſome of the former Articles.

In the firſt ſwingling of the Hemp there will be ſeparated from the finer Part a great Quantity of Refuſe, with Tops, Knobs, and half broken Pieces and Lumps. All theſe muſt be ſhook up together, and carefully dried. When this is done they are to be thraſhed with Flails, and by this Means the Lumps will be broken, and they are to be laid by; they ſerve for many coarſe Purpoſes, though they would never have broke or divided well with the finer Stuff. Theſe, by Way of Diſtinction, are called the Swingle-tree Hurds; though any of the Refuſe may be beat up among them: a great Care of the Owner being, that nothing which can be put to any Uſe be waſted.

When the Farmer purſues his Intereſt by dreſſing the Hemp farther, there will be more Hurds ſeparated in the ſecond ſwingling, and they will be of a better Kind; theſe, managed by the Wool Cards, make what is called Hempen Harden. They are not to be mixed with the other Hurds, for they are much better, and ſell at a more advantageous Price.

In the ſame Manner every ſucceeding Operation for the dreſſing the Hemp ſeparates a Quantity of Hurds, though it be every time ſmaller and ſmaller. Theſe are all to be laid by as they come out. They do not require thraſhing with Flails, in the Manner of the coarſe firſt Hurds and Refuſe; but being well managed with the Cards, they make ſo many Sorts of ſaleable Stuff at different Prices.

CHAP. XXXIX.

Of Woad.

WOAD is a Plant of eaſy Culture, and as eaſy Management; ſubject to few Accidents, and of a ready Sale. 'Tis pity that it ſhould be cultivated in ſo few Places. One Recommendation it has in which it exceeds any Growth, this is, that it yields three, four, five, and ſometimes ſix Crops in a Year.

It is a large Plant, with great blueiſh green Leaves, branched Stalks, and Multitudes of ſmall Flowers, followed by little Pods with the Seed.

The Root is long and covered with Fibres. The Stalks are thick, round, and upright, and they divide at ſome Height from the Ground into ſeveral Branches.

The Leaves ſtand irregularly upon them, and many very large ones riſe directly from the Root.

The Flowers are of the Shape of thoſe of Turnips, and the Seed is oval.

The Flower is placed in a little Cup, conſiſting of four oval coloured Leaves: it conſiſts in like Manner of four Leaves diſpoſed croſswiſe. There riſe in the Middle ſix Filaments, four of theſe are of the Length of the Leaves of the Flower, and two are ſhorter; they have oblong Buttons on them, placed Sideways, in the Center of theſe ſtand the Rudiment of the Fruit. It is oblong, ſharp on both Sides, and is no higher than the two ſhort Filaments; the Flower and its Cup falling off this ripens, and contains only one Seed, which is lodged in the Center.

There are ſeveral Kinds of this Plant brought for Curioſity out of different Parts of the World, but only one is worth the Farmer's Notice, this is the common or broad leaved Woad, called

Field Woad. There is a Kind with ſmaller and narrower Leaves, diſtinguiſhed by the Name of Wild Woad, but it differs little from the other. The Seed of this is ſometimes, by Deſign or Accident, mixed with that of the right Sort, and of this the Farmer ſhould beware; the only Difference is, that this Seed is ſomewhat ſmaller than the right. It brings up a very good Woad, but not equal to the other.

CHAP. XL.

Of the proper Soil for Woad.

THE Farmer is not to be tempted by the Advantage attending any Crop, to engage in the raiſing it, if he have not the proper Requiſites; and the very firſt of theſe is a proper Soil.

There are Plants that will ſucceed only in ſome one Kind, but Woad gives him his Choice of two or three: it muſt be ſown however on one or other of theſe, or it will never anſwer. Therefore, though he has this Liberty, let him ſee that he does not exceed it. The two Articles in a Soil that favour the Growth of Woad are, that it be dry, and that it be rich. When theſe happen together the Soil is perfect for the Plant; but ſeparately they will do. Any warm and dry Soil will do, though it be but poor, but the better the richer; and in a rich Soil Woad will do, tho' not ſo perfectly dry as it muſt be in the other.

What this Plant affects moſt is a rich warm Loam; but as Richneſs and Dryneſs are what favour it, Cold and Wet together will never fail to deſtroy it.

Clayey Soils will never do. This is to be the great Caution; and the next is, that be the Soil what it will, the Woad will not ſucceed upon it unleſs very deep, if there be a clayey Bottom. This depends upon the ſame Principle with the other, the Hatred there is in this Plant to Cold and Wet; for Clay holds Wet and always makes a Soil cold when it lies near the Surface.

Now from theſe general Hints the Farmer may very well ſettle his Practice in all the needful Particulars. Firſt let him avoid all Clays and clayey Soils for Woad, and next, when he is about to ſow it on any other, let him examine the Depth and the Bottom.

Woad is a large Plant and requires a great deal of Nouriſhment, therefore it muſt have Quantity, that is, Depth of Soil, at any Rate; and particularly it muſt when there is a wrong Subſtance underneath.

Theſe are the Cautions as to what he is to avoid, the next Conſideration is what he is to chuſe.

If he have a ſandy Soil that is not bare and poor, but enriched with a large Quantity of good Mould among it; this is excellent, and the deeper the better. If he have a Piece of Ground that has a Soil of pure mellow Earth to a due Depth, this is better ſtill; and in particular if he have Opportunity of breaking up a Piece of Ground near ſome great Town, where there has been a Garden, this is very proper.

It is worth his while to be careful in this Choice, becauſe the Profits will anſwer accordingly. For on favourable Ground he will have one or perhaps two more Crops in a Year, than on ſuch as is but moderately right.

Woad, like all other Plants which require a great deal of Nouriſhment, ſucceeds beſt of all upon a Piece of Ground that is new broken up for it; and in this Caſe none anſwers like that which has once been in the Garden Way, and which has been mellowed by Dung and great Tillage.

If there be a Piece of gravelly Ground where there is not too great Abundance of large Pebbles, and a good deal of Loam among them, this will do excellently. I have ſeen Woad thrive very finely, where it has ſeemed to grow among bare Pebbles; but there has been good Stuff at the Bottom.

Any Piece of light Limeſtone Ground will alſo do for Woad, with the foregoing Reſtrictions, that it be not full of very large Pieces of Stone; and that there be ſome Goodneſs and ſome Depth in the Soil.

Of all Places in England where I have ſeen Woad cultivated, the fineſt has been about Thorney in Northamptonshire. I had the Curioſity to examine the Soil in this Part of the Country, in ſeveral of their Fields, and found it all of one Kind, it was deep, rich, and of a blackiſh Colour; it conſiſted chiefly of mellow Earth, but with a large Proportion of a bright brown Sand.

What is more remarkable than any thing about this particular Soil is, that the Situation was low and ſubject to Wet. The Woad grows there in the Way of more Moiſture than I have ever ſeen it elſewhere, and yet ſurpaſſes all other in the Largeneſs and Fineneſs of the Leaf.

This is a particular Caſe, and I have inſerted it as ſuch, for the Sake of the Huſbandman who may chance to have Land of the Kind of this about Thorney, but in general a ſomewhat hilly Situation is beſt, and a dry deep Soil.

We have obſerved that Woad ſucceeds beſt of all upon new broke up Land, and the ranker this is the better the Woad will thrive; it ſerves excellently to prepare ſuch Land as this for Crops of Corn, for which it would otherwiſe be too rich at firſt: but on all other Occaſions, as well as this, the Woad is to be removed after a Year or two. It exhauſts the Ground, and never ſucceeds well in the ſame Place long together.

The new Method of Huſbandry might remedy that Inconvenience, and perhaps with the Aſſiſtance of a moderate Quantity of enriching Manure, the ſame Piece of Ground might be made to bear Woad ever ſo long; but this we ſhall mention more at large hereafter: the common Practice of Huſbandmen is what we conſider in this Place; and that requires that the Crop ſhould be removed the third Year.

CHAP. XLI.

Of preparing the Ground for Woad.

WHEN the Farmer has fixed upon a proper Piece of Ground for this Growth, his next Care is to prepare it for the Reception of the Seed; for without this he may, after his beſt Choice, reap but a poor Advantage.

All Plants that draw a great deal of Nouriſhment, require that the Soil ſhould be well prepared for giving it. This Preparation is beſt given it by frequent Tillage; and a careful and repeated breaking and dividing, and occaſionally enriching of the Ground. As it requires a great deal of Nouriſhment, a Piece of rich Paſture Ground new broke up for that Purpoſe, is better than one in Tilth for Corn, and the Woad will leave it in a very good Condition for any other Crops.

The beſt Way of preparing ſuch a Piece is, by turning it up firſt with the four coultered Plow, which we have deſcribed before. This will cut and tear all the entangled Roots of the Graſs, and turn up the Mould to a very conſiderable Depth.

After this plowing it ſhould be harrowed carefully, and if the Seaſon and Soil be both dry, it ſhould be then rolled, and afterwards harrowed again.

This being done, the Lumps broke, and Refuſe of every Kind drawn off, there ſhould be People ſent on the Ground, to pick off the large Stones or any thing elſe that breaks in upon the Evenneſs and Fineneſs of the Ground, and has eſcaped the Teeth of the Harrow.

This is the Cuſtom in the Land that is moſt fit for Woad, that is, ſuch as is dry and warm: when it is a little moiſter the beſt Way is to plow it in high Ridges, and then the Pieces of Turf, and other Refuſe that lie upon the Surface, when picked off, may be thrown into the Furrows to rot.

Whichever Method be followed, the Land when finiſhed for ſowing, ought to lie as level, and be as free from Lumps, as the Border of a Garden. Land that has been fallowed ſome time does very well for Woad; and I have ſeen it thrive excellently on a broke up Piece of any of the artificial Graſſes: but in any of theſe Caſes the Preparation muſt be exactly the ſame, and the Reward will be ſuited to the Labour and the Care.

CHAP. XLII.

Of ſowing of Woad.

THE Preparation of Land for this Produce having been ſhewn, there remains to enquire into the Time and Manner of doing it. In each of theſe there is ſufficient Matter of Choice to the Huſbandman, for neither the common Manner of diſperſing the Seed, nor the common Time of doing it are ſo proper as what may be adviſed.

In the firſt Place the Farmer is to take Care that he buy good Seed, and that he have enough of it: he is not to count that Quantity ſufficient which will do to ſow the Ground he intends for this Purpoſe. Woad is very apt to fail, or to be deſtroyed early in its Growth, he muſt therefore have a Supply of Seed by him, to let in and make up the Deficiences. Having his Seed and his Land ready, he may ſow it in the common Way or by the Drill. In the firſt Method a Gallon of Seed is enough for an Acre, and in the Drill Method half that Quantity is ſufficient, for Woad is large in its Growth, and a few Plants are enough upon the Ground.

In the common Way of ſowing, the Seed is to be ſcattered as evenly as poſſible over the Ground, by the ſingle Caſt, and then harrowed in carefully. In the Drill Huſbandry it is to be ſown in double Rows, with ten Inch Partitions, and with five Foot Intervals between two and two.

Few Crops are more difficult to be well managed in the common Huſbandry; and none eaſier in the Drill and Horſehoeing Method. The Leaves alſo grow much larger, and are in themſelves much better this Way.

As to the Time the common Farmer errs as much as he does in the Manner of ſowing. The common Seaſon for this is the Middle of FEBRUARY, but the proper Time is the firſt Week in AUGUST. The Woad ripens its Seed in the End of JULY; Part of the Plants are to be reſerved for that Purpoſe; and the Seed never puſhes ſo ſtrongly as when ſown as ſoon as fit for it.

This is the Courſe of Nature; and it would be well if it were followed in more Things. We ſee the Seeds of Plants ripening in AUGUST and SEPTEMBER, naturally fall to the Ground at that Time, or ſoon after, and they ſhoot in a few Days, their Leaves ſtand the Winter, and all that Time the Root is ſtrengthening itſelf in the Earth; ſo that when the Spring comes they are in a Condition to ſhoot with Strength and Vigour.

This being obſerved in Relation to Woad, the Growth will be much ſooner fit to cut for the firſt Crop, and every Way better. This firſt cutting will be the richer for the Time the Roots have been in the Ground, and the freſh Shoots will be the more vigorous for the next, it will come ten Days or a Fortnight earlier in the ſame Seaſon than it would have done in the Spring ſowing.

There is this farther Conſideration, the firſt Shoots of Woad are very apt to ſuffer by Inſects, in the Manner of Turnips and ſome others. It is for this Reaſon we have cautioned the Farmer always to have a Supply of Seed to make up Deficiences; but it is better to prevent them, and on this Occaſion the Autumnal ſowing is preferable.

When the Seed fails in ſome Part, and the Crop is ſupplied by freſh, this is a little backwarder than the firſt ſown; and when the Fly has deſtroyed a Part of the young Crop, and more is ſown, this laſt will be ſtill more backward in its Growth than in the former Inſtance. The Huſbandman would wiſh it ſhould be all equal, that it might come all to be cut together,

but

but this is not to be obtained, unleſs theſe Evils be prevented inſtead of remedied.

This is not, in either Caſe, to be done without a Poſſibility of failing, but it may be made greatly more ſafe and certain by the Autumnal ſowing.

I can ſpeak from Experience, that the Seed ſown in Spring is, in this Kind, much more ſubject to fail than that in Autumn; and alſo that the Fly or Grub, ſo deſtructive of the young Growth, is much more frequent in the former than in the latter Seaſon.

As to the Goodneſs of the Seed, that depends in a great Meaſure on its being new. Seed ſown in FEBRUARY muſt be ſeven Months old, and it may be nineteen or twenty Months. And for this it is always the worſe in Proportion. It is a common Opinion among the Woadmen that two Year old Seed is as good as freſh, but nothing is more erroneous. They complain of bad Crops, and 'tis ſtrange they do not ſee into this, which is one principal Cauſe. I have made ſome of them try the Experiment, and the Difference has been this, that out of twenty new Seeds ſown, not above one, two, or three have failed; and out of as many old ones, eleven, twelve, or more; one would think this ſhould be convincing.

I have found in the ſame Manner by Tryals, that out of twenty Seeds of the ſame Crop, ſown in a Fortnight after their ripening, only two have failed; and out of twenty ſown from the ſame Parcel, the next FEBRUARY, four or five; this is as convincing an Argument as the other.

Theſe are Facts on which the Huſbandman may depend, let him therefore regulate his Buſineſs accordingly. Having thus laid down the beſt Method of ſowing this Crop, we ſhall proceed to inform the Huſbandman of the Way of managing it, whatever Practice he may have followed in ſowing.

CHAP. XLIII.

Of managing Woad in the Growth.

WE ſhall here direct the neceſſary Conduct for every Kind of Crop of Woad. We will ſuppoſe then firſt, that the Farmer have followed the old Method, and ſown his Land in FEBRUARY by hand. In this Caſe he will ſee it come up irregularly, and when it has been a Week above Ground, he muſt obſerve how it ſtands; if the Grub or Fly have been at Work, he muſt ſend in a careful Perſon with a Dib in his Hand, and a Parcel of Seed in his Apron. With the Dib he is to make Holes, and into each Hole he is to put five Seeds, this is to be done wherever the young Crop is ſeen to be thinned; and theſe Holes are to be a Foot aſunder.

If the Farmer will ſow his Woad in Spring, the earlier he does it the better. This Plant will ſhoot in very cold Weather, and the earlier the Seaſon the fewer there are of thoſe Inſects, the warm Showers of the more advanced Spring bring them on in Abundance.

When the Plants from this new ſowing have got to a little Size, the Field is to be hoed. This is not only to be done to keep down Weeds; but to thin the Crop itſelf, for the Plants muſt not ſtand ſo cloſe as they riſe in this random Way; if they do they will ſtarve one another. The Hoers muſt be careful Perſons; they muſt have Orders to thin the Plants to about a Foot aſunder; and they ſhould leave the ſtrongeſt and moſt promiſing. In this Manner they will be refreſhed as well as thinned; and having taken good Root, and the preſent Crop of Weeds being deſtroyed, they may be left to themſelves; for they will not ſuffer any more to riſe among them. In this Manner they may be left to make their neceſſary Growth.

In the ſecond Place let us examine the State of a Crop ſown the firſt Week in AUGUST. In this, if the Seed have been the Produce of that Year, and the Ground well prepared for it, there will be little or no Need of examining it on Account of Deficiences. The Ground will be too well covered to need a Supply; and the Flies will have little Power.

At a proper Growth, as in the former Inſtance, the Hoers are to be ſent in, and they muſt thin the Plants in the ſame Manner as the others, and thus leave them for the Winter. In that Time they will make but a moderate Progreſs above Ground, but they will be all the while ſtrengthening themſelves at the Root, which is the Owner's true Intereſt. They will be juſt ſtrong enough to keep down the poor Shoots of Weeds, that ſhew themſelves in that cold Seaſon, and they will ſhoot apace into Leaves in Spring, affording an early Crop, and a very fine one; and leaving the beſt Foundation that can be for the next, that is, Strength at Heart.

From what I have ſeen practiſed by ſome particular Woadmen, in this common Way, I ſhall be able to give the ordinary Farmer who purſues it, ſome uſeful Hints. If he ſend in his Hoers again in Spring, to break the Surface of the Ground, and deſtroy all the Weeds between the Plants, this Practice will greatly ſtrengthen and refreſh them. Not ſo much for the Injury ſuch a few poor ſtarved Weeds could have done, as for the Advantage there is in breaking the Ground.

This ſuperficial hoeing leads us naturally from the common Practice of raiſing Woad by the old Huſbandry, to the Method we have propoſed for doing it according to the new, and to the Advantages of deep hoeing about Plants of ſo large a Growth.

We have adviſed double Rows and five Foot Intervals, becauſe a third or middle Row would want Air, and therefore its Leaves would never come to their Freſhneſs and Colour; and becauſe the Land between double Rows ſhould have Opportunity of good turning.

We will now ſuppoſe a Farmer to have ventured on this Method, and ſhall not fear to promiſe him a three-fold Succeſs, to what it was poſſible he ſhould have obtained by any other. The Method he is to follow in the Management of his Crop is this.

When the Plants in his two Rows have got ſome Bigneſs, he muſt ſend in the Hoers with their Hand Hoes. Theſe muſt clear away all

the Weeds in the Partitions between the two where the Horſe Hoe cannot come; and they muſt thin the Plants in the Rows. They muſt leave one every fifteen Inches, or thereabouts; and theſe alternately, not oppoſite one to another.

This will reduce the Number of Plants on an Acre to very few, but the Profit will be ſo much the greater. The Benefit of Woad is not from the Seed but the Leaf; and Experience ſhews, that one ſingle and vigorous Plant will produce more than five that ſtand cloſe and ſtarve one another: and what is yet more to the Owner's Profit, one Leaf of this will be equal in Goodneſs to ten of the others.

When the Plants are thus thinned, and the Weeds cleared away in the Partitions, the Horſe Hoe is to be ſent into the Intervals, this is to plow deep and turn up the Soil, thoroughly deſtroying the Weeds, and preparing the Earth to ſupply abundant Nouriſhment to the Plants.

As often as Weeds riſe in the Intervals, this Horſehoeing is to be repeated; and it will be beſt to uſe it alſo at certain Times, for the Advantage of the Crop in particular States.

To underſtand this perfectly the Farmer muſt be led to conſider the Nature of the Woad: its Value is in the Leaf; and that conſiſts chiefly in its fine Colour and great Freſhneſs. The Woad draws Nouriſhment apace while the Leaves are young, and ſo continues till they get a good Growth; but toward the Time when they are to be cut, being large, they are not ſo fully ſupplied, partly becauſe they require more Nouriſhment; and partly becauſe the Ground is in a Condition to yield leſs. We have ſhewn the Occaſion of this before, namely, that all Ground, from the Time of its being broken and divided by Culture, grows worſe and worſe till it is tilled again. Therefore when Plants want moſt Nouriſhment, they can obtain leaſt; and this is particularly a Diſadvantage to Woad, becauſe its Value depends upon the Freſhneſs of the Leaf, which relies upon the Quantity of Nouriſhment it can get juſt at that Time.

For this Reaſon let the Farmer who raiſes Woad according to the new Method of Huſbandry, contrive his Horſehoeing ſo that one of them may come juſt before the full Growth of the Leaf for cutting.

There is a Time when the Leaves of Woad have acquired their Size, and want only their Fullneſs and Colour; at this Period let him bring in the Horſe Hoe between the double Rows. The Earth will by this turning be filled with Nouriſhment. The Ends of the Roots of the Woad will be cut off, and new ones will ſhoot from them into the new Earth: thus in two Days the Crop will acquire a new Aſpect of the true freſh green Colour; and if ten Days after this Horſehoeing it be cut, it will be in the utmoſt Perfection whereof it is capable; and the young Shoots that are to riſe for the ſucceeding Crop, will ſhoot with great Vigour immediately afterwards.

From this it appears plainly, that though a Crop of Woad may be every Way very advantageous to the Farmer; it can no Way bring him nearly ſo large a Profit as when it is raiſed by the Drill and Horſehoeing Huſbandry. This Practice is uſeful for all Plants, but moſt for the largeſt.

As to the other Method, thoſe who follow it ſtrictly will yet reap enough Advantage to encourage them to continue the Crop.

CHAP. XLIV.

Of the gathering of Woad.

WE left the Farmer in the laſt Chapter, with his Field of Woad ſufficiently ſtocked with Plants, and not over-burthened with them; and free from Weeds. They were in this Condition declared capable of over-powering the Weeds in the common Huſbandry, and proper Directions were given for deſtroying them by the Horſehoeing; therefore the Farmer had only to wait their Growth, for gathering his firſt Crop.

At what Time of the Year this ſhall happen cannot be well determined, for it differs greatly according to the Manner of Huſbandry, and the Time of ſowing; and alſo in ſome Degree in Reſpect of the Richneſs or Dryneſs of the Seaſon.

All that can be ſaid in this Reſpect is, that Woad ſown in Autumn will be fit for a firſt Cutting, earlier than that ſown in Spring; and that the Woad raiſed by the Drill and Horſehoeing Huſbandry will be ready to cut earlier, and yield the ſecond Crop quicker than that managed according to the vulgar Practice. For the reſt, as the Seaſon is better, the Crop will be the ſooner ready.

As warm and light Soils are moſt ſuitable to Woad, ſo a warm Sun and light Showers raiſe it the quickeſt to Maturity; therefore the Seaſon will often make ten Days, a Fortnight, or ſometimes more Difference in the ripening of a Crop of this Plant.

Let the Owner, when it comes near ripening, watch it carefully; for on finding the exact Time of this depends a great deal of the Advantage. When the Leaf is full ſized, firm to the Touch, juicy, and of a freſh and fine Green, it is ripe for gathering; and as ſoon as it is that ſhould be done.

Nature, in moſt Things, changes ſwiftly, from a State of Perfection to Decay; and in nothing more than this Growth. If the Time of Ripeneſs in the Leaf be not ſeized, it preſently begins to fade, it firſt grows flabby, and then loſes by Degrees its Colour.

This firſt Accident is very hurtful, but the other worſe. The letting Woad ſtand but three or four Days too long, will reduce a very good Crop to the Condition of a very middling one.

Therefore when the Leaf is ripe let it be inſtantly cut.

As ſoon as cut it is to be ſent to the Mill, and the Farmer is to prepare for his ſecond Crop.

We have obſerved that Woad yields ſeveral Crops in a Year. In the new Huſbandry the Aſſiſtance of the Horſe Hoe is ſo great, that theſe are all nearly of equal Value, and at the ſame Time there are more of them; but in the

common Husbandry every Crop is inferior to the first, both in Quantity and Goodness. The Woad of the first and second Crop are sometimes mixed together; but those which come after must be kept separate, or they will spoil; or at least much reduce the Value of the whole.

As to Quantity in the common Husbandry, an Acre usually yields a Tun of Woad, but in the Horsehoeing Method there is no Doubt of its yielding a much larger Store.

Woad will stand some time and yield successive Crops, but it is not advisable to trust the old Roots too long, 'tis therefore to be renewed after the second Year, with all the Care that we have described as necessary at the first sowing: this is an Expence and Trouble it very well answers.

CHAP. XLV.

Of renewing a Field of Woad, and of obtaining the Seeds.

WE have mentioned the Necessity of renewing the Woad Field, and we have given the Farmer great Caution with Respect to the Choice of his Seed. These are Articles which naturally fall in with one another.

It is the Course of Nature in the generallity of Plants, that the large Leaves which rise immediately from the Root fade, when the Stalk grows up: therefore, as these Leaves are what the Farmer wants from this Use, he is not to encourage or suffer the Growth of a Stalk if he can help it, in the ordinary Course of the Crop: But when he wants Seed he must promote this Growth on certain Plants, that he may have it in sufficient Quantity for his future Occasions. This he is to provide for at the same Time that he renews his Crop for the usual Service.

We have shewn him the whole Manaagement of this Species, and we suppose him to have gone through the first Summer; what remains of the two Years Produce will be easily understood, as to its Use and Management.

When he has gathered the last Crop for the Summer, the Woad will continue growing. It will not rise to Leaves fit for the Common Service during the Winter, but what grow at that Season will not be useless. The Field will be a very rich, wholesome, and nourishing Food for Sheep, and their biting, far from doing any Harm, will prepare it for shooting stronger the next Spring.

After that it is to be managed exactly as the first Year, and the first Crops will be as good but not the following. The Owner will see toward Autumn, the Necessity of renewing his Plants, and he is to do it in this Manner.

When the last Summer's gathering is over, he is to plow up the Ground immediately for the receiving of fresh Seed, but in this he is to observe a particular Caution; for he is to leave a Part of the old Roots, they being to afford the Seed for the succeeding Crops. The rest of the old Roots are to be harrowed up and thrown away, and these being left, and having the full Advantage of the new plowed Ground, thrive at a surprising Rate, and yield the next Year such a Quantity of Seed that an Acre will sometimes yield fifty Quarters.

This will appear the more surprising when the Reader recollects what we have said in the Description of the Plant, that each Pod has in it only one Seed; but the Number of Pods upon a Plant is in a Manner incredible.

When the same Piece of Ground is to be in Woad for a considerable Time, this is the Method of managing it; but we advise the Farmer rather to observe the Caution we have first given, and not keep any Piece of Ground more than two Years in this Crop; for in that Time, if the Land were ever so rank, it will bring it down to be fit for Corn, and if continued longer will impoverish it entirely: there is no Land that can stand the exhausting of so large a Growth cut so often, except it be refreshed and kept in Heart by the Horsehoeing Husbandry.

In this Method the Intervals, while they are plowed up for receiving the Roots from the Rows, enjoy in other Respects a Kind of Fallow, and after two Years the new Crop may be sowed in the Center of each Interval, and the Places that first held the Rows become Intervals in their Turn, to prepare them for the Crop at the next Change.

If even this should not prove sufficient to keep the Ground in Heart for this rapacious Crop, some Dung may be used, plowing it in in the Intervals. It must be old mellow Dung for this Purpose; and by this Practice the Land may be kept in sufficient Heart for any thing. There is no Crop whatsoever that may not be supported, by this Management, ever so long upon the same Piece of Land, breaking the Intervals often and well, and burying mellow Dung in them at Times, and finally changing, at proper Periods, the Places of the Crops, making that the Middle of the Interval at one Time, which was the Place of the Rows at another. This is the Practice we advise the Farmer for every strong Crop.

CHAP. XLVI.

Of Weld, or Dyer's Weed, and its Difference from Woad.

BEFORE we enter upon an Account of this Plant, which may well enough be called a Weed, as it grows wild by Way Sides as well as in Fields where it is cultivated, it will be necessary to observe one very natural and very frequent Mistake that is made about it, as it is an Error that may be very prejudicial to the Farmer; this is, the confounding it with Woad. Its Name Weld sounding somewhat like Woad, has led some into this, and its Use in dying like Woad seems to have confirmed them in it; but notwithstanding this Resemblance in Name and Use, the Plants are altogether different, and the Culture that belongs to one does not suit the other.

What is the more dangerous in this Respect

is, that thoſe who have written to inform the Huſbandman, have too often fallen into the Error. Mr. Houghton, whoſe Collections on Huſbandry and Trade are much eſteemed, falls into this Miſtake: he confounds the two as if they were one Plant, and orders for Woad what thoſe from whom he learnt meant of Weld, and what muſt ruin the Huſbandman who ſhould depend upon it. This Account is to be found in his 381ſt Number of the ſecond Volume, where his Account and the Directions following it do not belong to either Woad or Weld, but are made up partly of what belongs to one, and partly of what belongs to the other.

This will ſhew the judicious Reader the Neceſſity of thoſe Deſcriptions we have prefixed to each of theſe Heads, of the Plant itſelf, they may have appeared at firſt Sight to ſome ſuperfluous, and to others too particular, but here is a Proof that they are in neither Fault; that nothing can be more wanted than proper Accounts of the Plants themſelves, before we enter upon their Culture; and that theſe cannot poſſibly be too punctual or exact. Where ſuch a Perſon as Mr. Houghton ſhould miſtake, how is the common Huſbandman to ſuppoſe he ſhall eſcape; eſpecially when he is deſirous of improving his Ground by ſome new Product. There is no other Way but by a perfect Knowledge of the Plant itſelf: he who had ſeen Weld and Woad treated of as diſtinct Articles, and had read an exact Deſcription of each, could never ſuppoſe them both to be one and the ſame Plant, or miſtake one for the other; for ſcarce any two Herbs are more different. It is in this, as in all other Reſpects with relation to Huſbandry, in order to practiſe it ſucceſsfully, the Perſon muſt underſtand it thoroughly. This is what we have attempted to inculcate throughout our whole Work, labouring to make the moſt ordinary Reader know the Grounds and Reaſons of every Thing he is to practiſe, and in every Article begin at the Foundation.

CHAP XLVII.

What Weld or Dyers Weed is.

THOUGH the Names may perplex the unexperienced Reader, none who has once ſeen Woad and Weld, can ever in his own Mind confound them together afterwards. We are to endeavour here to ſupply the Place of that Sight of the Plants themſelves by the Deſcriptions and Figures we have given, and are about to give of each.

Woad we have ſhewn is a large Plant with broad Leaves, covering a great deal of Ground: weld on the contrary, is an upright, ſlender, and tall Plant, ſpreading at the utmoſt over but a very few Inches.

It naturally grows wild on the Banks of Ditches, and is frequent in this State all over England. Culture makes no Alteration in it, ſo that he who knows it wild, cannot miſs it in the Field.

It is very upright, and ſcarce at all branched. The Root is white and fibrous, the Leaves that riſe from it are long and very narrow. They lie ſpread in a Circle upon the Ground, covering a Spot as big as a ſmall Plate; they are ſmooth, gloſſy, and of a pale but freſh green.

The Stalk riſes in the midſt of theſe, and has a great Number of Leaves upon it like thoſe of the Root, but ſmaller. From the Middle upwards, it is covered with Flowers, theſe are very ſmall and yellow, and they often ſtand in a kind of Spike of near two Foot long: after them come the Seeds, which are very ſmall, and are contained in open Seed Veſſels, a vaſt Number in each.

The Structure of the Flower and Seed Veſſel is this. Each Flower ſtands in a ſmall green Cup, formed of a ſingle Leaf, divided into four ſlender pointed Parts, two of which gape open more than the others.

The Flower is compoſed of three little yellow Leaves, placed one uppermoſt and two ſideways. The upper one is lightly divided into ſix Parts; the two ſide ones are each divided into three Parts in the ſame Manner. Sometimes there are beſide theſe three, two other ſmaller Leaves in the Flower: theſe are undivided, and ſtand at the Bottom, but many Flowers are without them. The upper Leaf is rounded at the Bottom, and has there a little Receptacle for a ſmall Drop of Honey Juice; this Receptacle is flattiſh, and ſtands erect juſt under the Leaf.

Within this Flower there are a Multitude of fine ſmall Threads, each having a little upright Button on its Top. In the Centre of theſe ſtands the Rudiment of the Fruit, or Seed Veſſel, this is rounded, and has three Points riſing from it of the Length of the Filaments. Theſe receive the Duſt from the Buttons at the Tops of thoſe Filaments, and convey it down from their Tops to the Embryo Seeds in the Rudiment.

When the Filaments and Leaves of the Flower are fallen off, this Rudiment remains in the Cup and grows larger, it becomes at laſt ridged and riſing; the three Points remain upon it, and it is open juſt at their Origin. The Seeds are numerous and very ſmall. When nearly examined, they are found to be of a Kidney Shape, and they grow to the Inſides of the Ridges of the Veſſel.

This is the Structure of the Flower and Fruit of this Plant, it was known to the Antients by the Name of Luteola, and in ſome Places we call it Would, which comes nearer the Name of Woad than the other. It ought therefore always to be called Dyers Weed, for the ſake of Diſtinction.

The Antients called it Luteola, which ſignifies the yellow Plant, either from its yellow Aſpect when in flower, or elſe for its Uſe in dying yellow, with which they were acquainted, and to which Purpoſe it is uſed at this Time; in this it differs from Woad, which does not afford a yellow but a blue Colour.

The Huſbandman can need no Advice as to what Kind he ſhall chuſe, for there is but one that deſerves his Notice. We have a little Sort of Dyers Weed wild in ſome Parts of England, but it is a trifling Plant, and not worth

Notice,

Notice, the other is sufficiently distinguished from it by its Bigness.

CHAP. XLVIII.

Of the proper Soils for Dyers Weed.

NATURE points out the proper Soil for this Plant, and that is no small Recommendation of it to the Husbandman, for the same Observation shews, that a very poor one will do. We see the Plant wild, and we see it flourish in that State; and its general Situation is upon a Ditch, Bank, or other dry and poor Piece of Ground; often upon a Wall, and very frequently upon almost bare Sand, or entire Gravel. Nature therefore points out a poor, barren, dry Soil for the cultivating of it; and the Farmer who has Uses enough for his best Land, will be very glad thus to know what to do with his worst.

Weld will always grow upon this with very little Expence of dressing, and it is a Commodity of certain Sale to the Dyers, and of no mean Price.

Let the Husbandman who intends to raise Weld, fix upon some poor, barren, sandy Field, if he have such a one; if not, let him chuse the driest Piece of Ground he has, if it be better than needs, let him not grudge it to this Crop, for he will find a proportioned Advantage. The Weld will grow upon the poorest Ground, it will thrive better, and grow larger upon such as is somewhat richer, provided it be of the right Kind.

I have observed several Pieces of Ground to the South West of LONDON, where the Soil consists only of Sand, and a black Mould; this is the best Ground that can be pitched upon to yield Dyers Weed in large Crops. It is a Sort of Land that requires a great deal of Manure to make it yield well in the common Way of Husbandry, wherefore this would be a very great Improvement: such Land will bear great Crops of this Plant from Year to Year, without any Expence of Manure, and with very little Culture.

In many Parts of HERTFORDSHIRE and BUCKINGHAMSHIRE, they have dry parching Gravels, which yield very little in the common Way of sowing, and that at a very considerable Expence, these would bear Dyers Weed in great Plenty at small Expence.

These Soils, as also all poor Loams that are over sandy and even, the Heath Land that lies dry will bear it; and in many Places Estates may be made by the Culture only of this trifling Article, for so it is in respect of the many others usually sown.

Now that we have shewn the Farmer the Advantage of raising Dyers Weed, we must caution him in one Respect; that is, that when he has found a proper Piece of Land for it, he examine whether there be a Purchaser for the Commodity near him.

As much as this Plant is neglected, there is not any one whatsoever that is more fit to improve Estates in many Places, but it would be easy to overstock the Market; and there are Places where there wants the Convenience of a ready and unexpensive Sale.

Under these Considerations, few Things can be more advantageous than the cultivating this Plant, and nothing is more easy.

CHAP. XLIX.

Of the sowing of Dyers Weed alone.

WE have observed that there needs no particular Preparation of the Land for the Reception of this Seed, but there is none that requires more particular Caution in the Sowing.

This may be done either alone or with some other Crop; and of these two Ways the first is preferable for very poor Soils, and the latter for such as are somewhat better.

When a poor Piece of Land is to be sown with Dyers Weed alone, nothing more is needful than Plowing, and once Harrowing. As to the Time of sowing it, the Husbandman may take his Choice of Spring and Autumn, but the Autumn is vastly preferable.

We have observed that the Seed is extreamly small, therefore a vast Number goes to a small Measure. This makes a little Seed by Measure suffice; but there is a great deal of Difficulty in scattering so small and light a Seed tolerably equal over the Ground.

When the Land is ready, let the Husbandman procure good Seed in the Quantity of a Gallon to every Acre. This is the usual Allowance, and if properly distributed it is enough; the Number of Seeds being very great in this Quantity; but in all the Observations I have made, I never saw a Field that had any tolerable Regularity in this Respect.

The Farmers have a Custom of mixing Dust with the Seed before sowing, to make it spread the more evenly, but this does not succeed. 'Tis scarce possible to sow so small a Seed by Hand alone, but the best Crops shew how imperfectly this Practice answers the Purpose.

We have before us at this Time, a Letter from a very ingenious Correspondent on this Subject, which proposes a great Improvement founded upon the Principles of Reason, and established by Experience. We thank this Gentleman in the Name of the Publick, and wish for the Sake of Mankind, he would extend his Observations to more Subjects, and that others would follow the same useful Steps, we should then see Husbandry appear with a new Lustre.

To the AUTHORS of the BODY of HUSBANDRY.

GENTLEMEN,

" Permit me to give you the most essential
" Proof of my Regard for your Undertaking,
" by contributing my Mite toward the publick
" Benefit. What I have to relate to you re-
" gards a single Article, and one usually e-
" steemed but inconsiderable; but it is one
" which I am sufficiently certain might, with
" proper

" proper Management enrich many a Land-
" owner or Farmer.

" The Plant I mean is Dyer's Weed, and
" what I have obſerved and practiſed concerning
" it as follows.

" Obſerving that the pooreſt Places abounded
" with this Weed, I reſolved to try a Crop of
" it upon a Piece of Land I had, that ſcarce
" yielded me any thing; and not having an Op-
" portunity of buying the Seed, I ordered a La-
" bourer to gather it for me from the Banks,
" and other waſte Places, when ripe.

" I am ſituated about eight Miles from the
" Sea, in the County of Essex. I went with
" my Labourer to ſhew him the ripe Plants,
" and ſee he made no Miſtakes; and thus
" had an Opportunity of obſerving the natural
" Growth of this Plant in different Places.

" I found this Particular, that upon the ſame
" Soil, and under all the ſame Accidents, the
" Plants were larger and finer between me and
" the Sea, for two or three Miles, than they
" were on the other Side.

" You will perhaps think it Fancy, and ima-
" gine that the Sea can have no Effect on the
" Growth of a Plant, at five or ſix Miles di-
" ſtance; but having ſtudied Botany in my
" younger Time, to me there was nothing won-
" derful in this, though I ſoon determined to
" make the Diſcovery uſeful. There are on
" the Side of my Eſtate, for the little Land I
" cultivate is my own, that is next the Sea, ſe-
" veral Sorts of Trefoil that are not found on
" the other Side, though the Soil be the ſame;
" and I have obſerved that ſeveral wild Herbs,
" which will not grow within the Reach of ab-
" ſolute Salt Water, yet either grow in no other
" Places than ſuch as are four, five, or ſix
" Miles diſtant from the Sea; or no where ſo
" thrivingly.

" From theſe Obſervations, made at a Time
" when I little thought they would be uſeful, it
" appeared no Wonder to me that Dyers Weed
" ſhould thrive better within this remote In-
" fluence of the Sea, than elſewhere, though it
" grows naturally in all Parts of the King-
" dom.

" Upon this Obſervation, and the Practice of
" our Farmers, of mixing dry Road Dirt among
" the Seed of Dyers Weed, to make it ſpread
" more equally in ſowing, I founded the follow-
" ing Practice, which anſwered my utmoſt Ex-
" pectations, and which is the Occaſion of this
" Letter.

" Having got together a good Quantity of
" Seed, I ſpread it on the Floor of a Garret to
" Air, and in the mean while ordered my bad
" Piece of Land to be twice plowed and har-
" rowed very even. It is one of thoſe brown
" duſty Soils that we ſee on the Heaths of Sus-
" sex.

" Having meaſured out five Gallons of Seed,
" for my Piece is near five Acres, and this is
" the common Allowance; I ordered ſome fine
" ſmall red Sand that lies upon our Coaſt, to
" be brought in wet from the Sea, being pared
" away juſt where the Tide was run off. I
" ſpread this to dry a little in the ſame Garret,
" and when it would juſt break I meaſured two
" Buſhels and a half of it to my five Gallons
" of Seed; I ſaw theſe well mixed with a ſmall
" wooden Scoop, and then ordered them to be
" ſown. This was the ſecond Week in August.
" The Seed came up very regularly and ſtrong,
" the lower Leaves ſtood the Winter, and in
" Spring the Stalks ſhot up; I had my Dyers
" Weed ripe three Weeks before my Neigh-
" bours; and by the concurrent Teſtimony of
" all who underſtood it, I had twice as much as
" ever was raiſed upon an equal Piece of Ground,
" in the Memory of Man.

" This great Advantage I attribute to ſeveral
" Cauſes, all owing to the Mixture of the Sand
" with the Seed; but having related to you the
" Fact, which is the uſeful Part, I ſhall be ſhort
" upon the reſt. In the firſt Place my Piece of
" Ground was a barren Earth, therefore the Ad-
" dition of the Sea Sand enriched it; for though
" but ſmall in Quantity, the ſpreading it even
" was a great Advantage.

" In the next Place the Soil was rendered
" ſomewhat lighter and warmer than before,
" both which Qualities fitted it the better for
" this Plant.

" Thirdly, The Seed was by this Means very
" evenly diſtributed over the Ground, for by
" ſowing it by hand in a careful Manner, where
" freſh mixed; and before the Sand was tho-
" roughly dry the Seeds ſtuck to one or other
" of the Grains of Sand, and the Weight of the
" one carried the other along with it; whereas
" in the common Way of mixing the Seed of
" this Plant with dry Duſt, the Duſt goes one
" Way and the Seed another; and though the
" Duſt be very evenly ſprinkled, the Seed is
" not.

" But laſtly, the great Aſſiſtance of all I at-
" tribute to the Salt hanging about the Sea
" Sand. I doubt not but you very well know
" how rich an Improvement Sea Sand is to
" Land, and how vaſtly preferable to that of
" Pit or Rivers: in this Caſe every thing con-
" curs to make it take the fulleſt Effect. The
" Improvement it makes in the Soil is what ex-
" actly ſuits it to the Crop; the Richneſs it
" gives is conveyed directly to the Plant in its
" firſt Shoot, the Sand being ſown with it; and
" finally here is the Advantage of that little
" Saltneſs, which ſo well agrees with this par-
" ticular Plant, conveyed to Land which lies
" too remote for the Influence of the Sea.

" Whatever you determine concerning my
" Reaſonings, the Facts are certain, and they
" are ſufficient. I hope to ſee the Improvement
" communicated to the World by your Means,
" and practiſed wherever there is a proper Land
" for this Growth, and Sea Sand within a pro-
" per Diſtance.

" I wiſh your Endeavours the Succeſs they
" deſerve, and am with Reſpect,

Your humble Servant,

Chriſtopher Hawkins.

We can add nothing to this Account of the beſt Method that ever was invented for ſowing of Dyer's Weed alone, but ſhall proceed to the Way of ſowing it with another Crop.

CHAP.

CHAP. L.

Of sowing Dyers Weed with another Crop.

AS the second Year is the Time at which the Dyers Weed comes to its Perfection, it may very well be sown with another Crop to save Trouble; the small Advance it makes under the Shade of that more speedy Growth, during its Continuance on the Ground, being sufficient to give it Strength in the Root for the ensuing Year.

Some Trouble and some Charge are saved by this Management, therefore many will chuse it; and these are to be informed that there are only two Crops proper for its being sown with, these are Barley and Oats: in either of these Cases the Seed is to be mixed in the Proportion of a Gallon to an Acre, with the Seed Corn of either Kind; and when sown together with that it is to be rolled into the Ground. It will shoot up soon after the Corn, and will continue alive among it, though with a weak Aspect.

As it now only sends up the Leaves from the Root, and they lie naturally spread upon the Ground, and will bear trampling, it will get no Harm from the necessary treading down in the Harvest, nor from the Instruments used in that Employment.

All this Time it has stood just alive, but as the Roots of the Stubble decay, and there is no other Growth to exhaust the Nourishment from the Ground, it will, having Air and Food, begin to strengthen itself and acquire a Look of Health and Vigour. In this Condition it will stand thro' the Winter, and then it will shoot up in Spring and presently come to a fine and rich Growth.

In this Case, as in the Method of sowing alone, the Difficulty is to scatter the Seed equally over the Field. This is not done by mixing it ever so evenly among the Seed Grain, because the Weight of the Grain throws it forward, according to the Direction of the Hand, but this light Seed does not keep it Company. For this Reason I should be for using the ingenious Method of our Correspondent, even in this Case, only mixing the Sand in about half the Proportion which he allows for the sowing of it alone. This will have the same Effect of spreading it equally, and, far from injuring, will be an Advantage to the Corn; the Quantity of Salt Sand, though small, yet being enough to do some Service in the Way of a Manure. This is the best Method of sowing Dyers Weed with another Crop, but however some may please themselves with the Fancy of the Money they save by it, the other is greatly preferable.

CHAP. LI.

Of the Management of a Crop of Dyers Weed in growing.

WE have said less Trouble is required for this than most Crops, but of the little that is needful nothing should be omitted. We have shewn how little Preparation of the Ground is necessary for the sowing this Plant alone, and having delivered the best Method ever invented of raising it in this Manner; we are to consider it as it rises, and in its Growth.

If the Season prove dry the Seed will be some time in the Ground before it makes any Appearance, but after a little Rain it shoots up, and the Leaves are of a pretty Green.

When the Leaves are of some Bigness, and spread with Strength, Hoers are to be sent into the Ground: they are not only to cut up the Weeds that rise among the Plants, but to thin the Plants themselves. In this Caution is to be used: the Shoots will be too thick in many Places, but 'tis to be remembered, that this is an upright Plant with few Branches, it may therefore stand much closer than others.

About nine Inches Distance is sufficient for these Plants, and if on any Part they are thinner by the irregular Distribution of the Seed, it will be proper to thin them to that in other Parts, by pulling up instead of cutting away the Plants, and so transplanting as many of them as are wanted.

When the Field is thus left properly stocked with the Plants, it is to remain untouched during Winter: in Spring the Owner should go over it, and if it be a poor Soil he will probably find little or no Occasion for more Trouble; but if a rich one, Weeds will naturally be grown up in it, and in this Case it must be hoed again. This is done at a small Charge, and is very well worth while, it so happily and perfectly provides for the Growth of the Crop.

After this the Dyers Weed is to be left to itself till the Time of gathering. The Strength it has got at the Root in the Autumn, and during the Spring, will be shewn in the Shoot at this Time; and no Weeds will be able to live near it. From this Time it will shoot up very fast and if some warm Rains fall as the Stalk is rising, they will add greatly to its Height.

CHAP. LII.

Of the gathering of Dyers Weed.

THIS is one of those Crops that is to be gathered by pulling: the Roots are of no Service after the Stalk has risen, and consequently the Method is to tear it up by them. This is to be done in the same Manner as the pulling of Flax, but with more Care on Account of the Seed. We have observed, in the Description of the Plant, that the Seed Vessels are naturally open, so that this is easily scattered and lost: the more as it is so extreamly small; and this the Owner is to guard against as much as possible, because of its Price; the Seed in this Crop being no little Addition to its Value. Though very small it is produced in a prodigious Quantity; every Stalk being half Way down covered with Seed Vessels, and these quite full of Seed, and its Price, one Year with another, being ten or twelve Shillings a Bushel.

For the ſaving of this not only a great deal of Care is to be taken in the pulling up the Plant, but the proper Time for that Operation muſt be watched ſtrictly. This alſo is neceſſary on Account of the Herb itſelf, and its Uſe to the Dyer.

There is a Degree of Ripeneſs at which it is perfectly ſuited to his Purpoſe; before that Period it is unripe, and immediately after it changes greatly for the worſe, by a beginning Deadneſs and Decay. Happily for the Farmer this Period of Ripeneſs of the Stalk is exactly that of the Seed, but he muſt therefore be doubly careful to watch when it arrives, and ſeize upon it.

When the Stalk is ripe for the Dyer the Seed has its full Growth and Maturity. It requires only to dry and harden a little, and this may as well be done out of the Ground as in.

To find this exact Seaſon for pulling the Crop, the Owner is to watch the Colour and Aſpect of the Stalk, and of the Spike of Flowers.

The Stalk is at firſt of a faint Green, but when it ripens for Uſe it grows yellowiſh; this is the firſt Signal of its being growing ready for pulling. When this is perceived let the Farmer examine the long Spikes of Flowers and Seeds. The whole Field generally ripens very regularly, ſo that judging by two or three there will be no great Danger of Error. If there be many Flowers on the Spike downwards, and the Seed Veſſels at the lower Part be green and ſoft, 'tis not yet ready; but by Degrees theſe Seed Veſſels toward the Bottom of the Spike grow hard, and there are only a few Flowers toward the Top of the Plant, and then the Seaſon of gathering approaches. If there have been Wet there will continue new Flowers ſhooting after the Veſſels harden, but theſe are not to be regarded; the proper and preciſe Time is when there are a very few Flowers, and thoſe only at the Top, and when the loweſt Seed Veſſels are hardened, and have the Seed looſe in them, and the reſt are hardening. This is the proper Ripeneſs of the Dyers Weed; the Stalks never fail to grow yellowiſh at the ſame Time. When the Weather is fair this Condition of the whole Plant comes on very regularly and very favourably; and the Farmer who watches it from the firſt Appearance to the laſt, cannot fail of knowing it exactly.

When the Crop is thus ripe the Pullers muſt immediately be ſent into the Field, with Orders to get it all up with Expedition. The Cautions to be given them, if unuſed to this Crop, are theſe, they are to draw it up as upright and with as little ſhaking as poſſible; and then keeping it ſtill upright they muſt tie it into ſmall Bundles, and ſet them up to dry.

There would require Difficulty and Trouble to get up the Plants in this Manner, if pulled before Ripeneſs; but when the proper Period is obſerved, the Seed being ripened, the Roots are of little farther Service, their ſmall Fibres rot off, they loſe their firm Hold of the Ground, and come up with great Eaſe.

When this Herb is dry it is fit for Sale, but the Seed is of no Uſe to the Dyer, nor would at all add to the Value in his Eye. Therefore the Farmer is to take Care to get it out for his own Supply, and for Market.

To this Purpoſe, when the Handfuls have ſtood to dry a little in the Sun, he is to have them houſed; and after a little Time he is to examine and ſee if the Seed be all hardened. When it is he muſt throw the Bundles on a Floor and thraſh them lightly, to ſeparate the Seed. A very little Violence anſwers this Purpoſe. Shaking alone would very nearly do it. When the Seed is out it is to be left on the Floor three or four Days, to dry and harden more perfectly, that it may not be in Danger of damaging by keeping; and then is to be ſwept up and cleaned.

The whole Herb is to be ſold to the Dyers; and it is ready for them as ſoon as thraſhed. The Seed is to be ſold, reſerving a ſufficient Quantity for the ſucceeding Crop, and this is to be ſown as ſoon as it is thoroughly dried. Two good plowings and one harrowing will prepare the ſame Ground for it again; and thus two or three Crops may very well be raiſed without Expence. After this it is better to change the Crop than manure the Ground, for Dyers Weed is one of thoſe Plants that do not like Dung.

CHAP. LIV.

Of Coleſeed.

THIS is a Produce confined, in a Manner, to a few Parts of the Kingdom, but that might very well be carried to others. We ſhall ſhew the Profits to the Huſbandman in general, and if we can tempt him to cultivate the Plant, ſhall not leave him deficient in any Article regarding the Management.

There is the leſs Reaſon to wonder that Coleſeed, ſo profitable in ſome Parts of the Kingdom, is ſo little raiſed in others, for this, that the Plant itſelf is leſs known than any other among the whole Number of thoſe cultivated for Uſe. To aſk what Herb it is that yields this Seed, is a Queſtion that would puzzle many beſide the Farmer. Even its Name is not commonly known. Coleſeed is the Name of the Seed only, it is alſo called Rape Seed, but this does not lead to the Matter; Cole is not the Name of any Plant, and Rape ſignifies Turnip: we ſhall explain this Matter, and before we enter upon the Culture ſhew the Farmer what the Herb properly is that he is to cultivate.

Coleſeed is very well known in LINCOLNSHIRE, and ſome other Counties; and Rape Oil is as well known, which is made from it.

The Seed is known at the Shops, and the Plant by the Farmers who raiſe it: but nothing more. In ſome Places the Seed is ſown among the other Kinds of what are called young Salleting; but in this Caſe, as the firſt Leaves only are eaten, no more is ſeen of it.

All the Time that this Ignorance remains about the Form of a very uſeful Plant, it is common wild on our Ditch Banks, and there needs nothing more than to ſhew its Seed to the LINCOLNSHIRE Farmer, for him to ſay that is it.

Theſe

Theſe are the Inaccuracies and Errors which ſo greatly retard the Progreſs of Improvements in Huſbandry. The Articles are themſelves unknown to thoſe who ſhould be the Authors of thoſe Amendments.

The Price of Coleſeed, if the Farmer chuſes to ſell it in that Condition, is very conſiderable, reckoning the Quantity an Acre yields; and if he will be at the Trouble of drawing the Oil, the Method of doing it is very eaſy, and his Profit vaſtly greater. Nor are theſe all the Advantages he receives from the Growth of this Plant: it is like the Dyers Weed in this, that it will grow on Soils which will not yield any thing elſe to Advantage; and though theſe are of a very different Kind from thoſe peculiar to the Dyers Weed, that flouriſhing on the moſt dry, and this beſt on marſhy Grounds; yet there are enough of theſe laſt in many Parts of the Kingdom, to ſhew how advantageous it muſt be to the Nation, to render the Plant more known, and the Culture of it among our Farmers more univerſal.

CHAP. LIV.

Of the Coleſeed Plant.

THERE is no other Name by which we can treat of this intelligibly to the Farmer, than this form'd from the Seed: what Herb it is that is thus called in the Coleſeed Countries, or what is the Plant that yields Coleſeed, we are about to ſhew.

There are three Kinds of Plants, each containing ſeveral Species, and diſtinguiſhed by different Names, but very nearly agreeing in their Flowers, Seed Veſſels, and other general Circumſtances; theſe are, 1. The Cabbage Kind. 2. The Turnip Kind; and 3. The Navew Kind. The Confuſion that has been made among theſe, has been one Occaſion of the Uncertainty about the Coleſeed Plant.

The Root of the Turnip Kind, and the Stalk of the Cabbage Kind, are what principally diſtinguiſh them; as to the Navew it differs very little from the Turnip, and that principally in the Smallneſs and Length of the Root.

The Flowers of all theſe are alike, and the Seeds of them all reſemble one another, and they will all, in the ſame Manner, yield that Oil which we call Rape Oil; but there is one Kind that yields it in greater Quantity than the others. This is the wild Navew, called Napus Sylveſtris by Authors, and this is the proper Coleſeed Plant.

The Turnip and Cabbage Kind we have in our Gardens in great Variety, and ſome have for Curioſity introduced the Garden Navew, or Napus Sativus, but it is inferior to the Turnip, and therefore little regarded. The Authors who figure and deſcribe the Garden Navew, figure alſo a wild Kind, and this is what we have on the Banks of Ditches. We have obſerved that the Navew differs little from the Turnip, except in the Shape and Bigneſs of the Root; and this Plant, which otherwiſe much reſembles the Turnip Kind, yet is properly a Navew, becauſe it has a very ſmall Root.

This is the wild Napus, whoſe Seeds are preſcribed in Medicines; and it would be better the Apothecaries gathered them from the Fields, or bought them under their proper Name at the Shops, than uſe Turnip Seed, as is the uſual Cuſtom, in their Stead.

We generally receive the Seed from Holland or Flanders, and I have ſeen that the Seed from different Places is not all of the ſame Kind. I have obſerved a Field of the yellow Turnip raiſed from Coleſeed, brought from Flanders; and another of a particular Plant of the Cabbage Kind, raiſed from Seed from Holland. Theſe were equally called Coleſeed, and they anſwered the Purpoſe; the Seeds were ſmaller in the firſt, and duſkyer in the latter, than thoſe of the wild Navew or right Coleſeed Plant, but they each yielded a good Quantity of Oil.

Any of theſe Kinds therefore will anſwer under the Farmer's Hands, but as the wild Navew yields much the finer Seed, and much the larger Quantity of it, and that is alſo richeſt in Oil; 'tis beſt to cultivate that particular Kind. This is oftener to be had from Holland than any where elſe, and we ſhall inform the Purchaſer how he is to know it by the Eye.

The proper Coleſeed Plant, or wild Navew, is four Foot high, and of an irregular Growth. The Root is long, ſlender, and white, 'tis of a ſweet Taſte like a Turnip, but with ſomewhat more Warmth. The lower Leaves are long, large, deeply divided at the Edges, and of a duſky Green. One Stalk uſually riſes in the Midſt of theſe, ſometimes two or more. This is round, ſmooth, of a pale Green Colour, and divided into many Branches toward the upper Part. The Leaves upon this ſtand one by one, not in Pairs, they are ſmaller and narrower than thoſe from the Root, and are of a paler Colour. The Flowers grow at the Tops of all the Branches, they are ſmall, of a bright Yellow, and perfectly reſemble thoſe of the Turnip: after theſe come Pods, which contain the Seed. This reſembles Turnip Seed, but that it is larger and ſmoother. The common Appearance of the Plant in Summer, is with long Spikes of Pods, and a few Flowers at the Top of each.

This is the Appearance of the wild Navew in our Fields and on Banks. When it is cultivated for Coleſeed it grows ſomewhat taller and more branched, otherwiſe there is no Difference; and in good Ground the Root will be larger and more tender. There is no Difference between this wild Navew and the Garden Navew, except that the Root of the Garden Kind is yet tenderer and thicker; but this is principally while it has only the lower Leaves, for when it is ſuffered to run to Seed the Root grows ſtiſky in the Garden. Indeed there ſeems no other Difference between the Garden and the wild Navew, but what is made by Culture.

The Flowers and Fructification of the Coleſeed Plant, when nicely examined, are thus formed. The Flowers ſtand in a Cup compoſed of four little oval pointed green Leaves, and this does not remain after the Flower is faded, as in the Dyers Weed, but periſhes and falls off with it.

it. The Flower is compoſed of four plain narrow yellow Leaves, placed croſswiſe. Theſe are broadeſt at the Ends, and not at all divided; they are of the ſame Length with the Leaves of the Cup. In the Centre of this Flower riſe ſix Filaments, four of theſe are conſiderably longer, than the other two: they have ſmall pointed Buttons growing on them. In the Centre of theſe riſes a ſmall upright Body, which is the Rudiment of the Seed Veſſel; this has a Kind of Button at its Top, in which there are ſmall Openings for receiving the fine Duſt out of the Heads of the Filaments; for in propagating the Seed, when the Leaves and Cup of the Flower are fallen, this Part enlarges, and at length becomes a Seed Veſſel of a longiſh depreſſed Shape, divided in the Inſide by a Membrane, which ſhews itſelf beyond its Extremity, and containing ſeveral large, round, bright Seeds.

This is the Conſtruction of the Flower and Fruit of the Coleſeed Plant, the proper Name of which is wild Navew, and which grow naturally wild, not only in ENGLAND but in FLANDERS, and other Parts of EUROPE.

The Seeds of the natural wild Plant may be gathered and ſown; but thoſe from ſuch as has been cultivated raiſe the ſtouteſt Plants, theſe therefore the Farmer is to chuſe, according to the following Marks.

CHAP. LV.

Of the Choice of the Seed.

WE would have the compleat Huſbandman not only introduce every Crop that can be profitable upon his Land, but would have him manage every Kind in the moſt profitable Manner. When a common Way of conducting himſelf will bring an ordinary Profit, we mean to ſtir up his Induſtry to new Methods by propoſing a much larger Advantage. This is the Caſe in nothing more eminently than the preſent Inſtance. Coleſeed is a very advantageous Growth, to the Farmer who takes leaſt Care or Pains to underſtand or manage it. But to him who will ſet about it on our Principles, it will yield a much greater.

We ſhall begin with the Seed, for without a due Care in the Choice of this all the ſucceeding Labour will come to little; now this is an Article in which Miſtakes are frequent.

We have obſerved that there are ſeveral Kinds of Coleſeed. Of theſe one is the right and proper Sort, and is in all Reſpects preferable to the others. Let the Farmer therefore be ſure that he knows, and next take Care that he chuſes this. The Seed of the Navew is this right and proper Kind; it is very large, ſmooth, and of a fine bright Colour. Let the Farmer keep theſe Marks in his Remembrance, and then examine ſeveral Parcels of Seed together, to ſee to which they beſt anſwer. All the Seeds ſold under the Name of Coleſeed reſemble one another, but the worſer Kinds are either ſmaller or of a duſkyer Colour, and leſs ſmooth Surface. 'Tis eaſy to be deceived, till they have been once ſeen together: but after this the right Kind will always be known by Sight, and the careful Huſbandman will be in no Danger of miſtaking any other for it.

The next Thing to being ſure of the right Kind, is taking Care it be in a right Condition. Coleſeed is a particular Seed, and is much eaſier damaged than Corn. It conſiſts of a great deal of ſoft pulpy Matter, under a thin Shell or Cruſt, therefore it is naturally moiſt. If it be not carefully kept it will grow damp, and this is a certain Deſtruction to it. Therefore let the Huſbandman take Care that he buys dry Seed, and ſuch as has been always kept dry; not what has been damp and dried again. He will know this by the Colour and the Smell. No Seed is ſo apt to damage by this Accident of Moiſture, and in this Caſe it gets a raw muſty Smell, which never goes off entirely, though it be ever ſo well dried afterwards. Alſo as ſoon as it becomes damp enough to be damaged, it loſes the fine bright Colour on the Outſide, and this it never recovers again perfectly.

Therefore the Sweetneſs and Brightneſs of the Seed are great Marks of its being in good Order; and if the Huſbandman keep this in his Mind, and be careful in the Choice, he will rarely be deceived.

The next Thing to the buying it dry is the keeping it ſo, if there be any Time between the Purchaſe and the ſowing of it; for as this Seed eaſily receives Damage, it receives it alſo very quickly. The beſt Method, as ſoon as the Seed is bought, if the Ground be not entirely ready for it, is to ſpread it on the Floor of a dry airy Garret. This not only will preſerve it from Damage, but it is an Improvement upon the common Method of keeping it; and will make it ſucceed much the better.

Next to the Choice and Preſervation of the Seed, we are to adviſe the Huſbandman to take Care whence he has it. Although the Plant is equally a Native of ENGLAND and FLANDERS, yet it thrives more in the latter Place, and ripens its Seeds better; ſo that they are more perfect and are fit for the Production of the ſtrongeſt and largeſt Plants. FLEMISH Seed is always to be had; and it will be always to the Farmer's Advantage to get it.

The People in LINCOLNSHIRE and NORTHAMPTONSHIRE, commonly ſow the Produce of their own Crop, but this from time to time dwindles; and there is no Compariſon between a Field of Coleſeed raiſed from ſuch Seed, and one from FLEMISH or DUTCH Seed, other Circumſtances being equal.

While the Farmer gives the Preference to foreign Seed, let him take Care that he do not fall into another Error, that is, let him ſee it be not old.

All Seeds ſhoot the quicker and the ſtronger for being new; and none ſhews the Difference more than Coleſeed. I have ſeen the Experiment tried by Mr. GRESTONE, who for Curioſity ſowed the Seeds of ſeveral of his own ſucceſſive Crops, and tried them in a Piece of Garden Ground near one another. The laſt Years Seed was up five Days before ſome of the old, and above a Week before others; and the

Number of Plants from the ſame Quantity was alſo greater.

Theſe are very material Conſiderations. The Newneſs of the Seed in this Kind, may always be known by the Clearneſs of the Colour. 'Tis always impaired in this Character, when it has been kept any conſiderable Time.

Let the Huſbandman get a Quantity of this good and perfect Seed from Abroad for his firſt Attempt, and he may if he pleaſes ſow the Produce of that for two Years more upon his Land; but at the End of that Time, it will be neceſſary to have Recourſe to the ſame foreign Seed, to keep up the Credit of his Crops: and if he will be at the additional Expence of foreign Seed every Year, he will be repaid with great Intereſt.

CHAP. LVI.

Of the proper Soil for Coleſeed.

WHEN the Farmer has procured a Quantity of good Seed, let him pick out the moſt proper Piece of his Ground for the Crop.

This will depend on the two great Articles, Soil and Situation; as to the firſt, the richer the Land the better; and as to the other, all that is required is, that it lie tolerably dry. There is no Part of ENGLAND where ſo much Coleſeed is raiſed as in the Fens, but the Lands are firſt laid dry that are intended for this Purpoſe: in the ſame Manner they cultivate it in FLANDERS and HOLLAND, on Ground originally marſhy; but they are at all the neceſſary Pains and Expence of making them properly dry firſt.

No Lands are more proper for Coleſeed than ſuch as have been ſubject to Overflowings, but they muſt be ſecure from that Accident while the Crop is upon them: and muſt be properly dry, in order to receive it.

Whether this Overflowing have been from Land Floods, great Rivers within Reach of the Sea, or the Sea itſelf, it prepares them equally for the Crop of Coleſeed. Thoſe where Salt Water has come, are properer than any others; but they require ſomewhat more Preparation.

There are Parts of ESSEX where the Huſbandmen might raiſe Coleſeed to a very great Advantage: and in many Places where Grounds have been newly recovered from the Sea by Banking, and the other Methods we have laid down for that Purpoſe, Coleſeed is an excellent Crop.

Every Piece of fat rich Land is proper for it; and the Farmer need not fear to beſtow it upon this Species, for it will yield to his full Content.

If he has a Piece of Ground that is too rank for Wheat, or the other uſual Growths, let him ſow it with Coleſeed: this will yield an extreamly rich Encreaſe, and the Land that would not before have done for Corn, will, by proper Management, be perfectly well prepared for it by this Means.

The right Soil for Coleſeed is mellow Earth. A ſoft deep black Mould, with little other Admixture, feeds it better than any other. The Plants never grow ſo robuſt, nor the Seed is not formed in ſuch Plenty, or ripened in ſuch Perfection on any other. This is the Reaſon that marſhy and fenny Lands, when properly fitted for the Purpoſe, anſwer ſo well with Coleſeed: this black deep mellow Earth is the natural Soil in theſe Places, one ſcarce ſees any other on breaking the Turf in any of them. This is of all others the beſt Soil for Coleſeed, but we have ſhewn it is not limited to this only, any deep Soil that is mellow, and properly ſituated, will do.

CHAP. LVII.

Of preparing the Ground for Coleſeed.

THE Soil we have recommended as moſt proper for Coleſeed, is one of thoſe that does not require any great Labour in Tilling; nor does the Coleſeed demand any particularly to its own Management. The black mellow Earth whereon this Crop ſhould be raiſed, cuts eaſily, and turns freely under the Plow; and when it is in a proper Degree of Dryneſs, breaks freely and finely in the working. All that is particularly neceſſary to fit it for Coleſeed, is to make it very fine; and this, unleſs the Seaſon prove quite unfavourable, or the Huſbandman be very unſkilful, is a Condition whereinto it is brought eaſily.

In MAY the Land intended for Coleſeed is commonly fallowed: in JUNE it is twy-fallowed; and in the latter End of that Month, or the firſt Week in JULY, the Coleſeed is ſown.

After the laſt Plowing, a fine toothed Harrow ſhould be drawn over the Field: after this, if the Weather be dry, let there be a light Roller carried over it; then let it be very gently and tenderly harrowed again. This laſt Harrowing, after the Roller has cruſhed and broke the Lumps, uſually make it as even as the Flower Border in a Garden, and this is the proper Condition wherein it is to receive the Seed.

If the Weather prove too wet, let the Rolling be deferred; and afterwards let it be performed with great Caution: for though the Roller may do great Good in this Caſe, it may alſo do much Harm. In ſome Lands the Soil is naturally ſo looſe, but once harrowing divides it ſufficiently.

CHAP. LVIII.

Of ſowing the Seed.

HERE we enter upon an Article which leads to very different Practices; and it is now the Farmer is to make his Choice which Method he will follow, that of the old, or that of the new Huſbandry. If he chuſe the old and beaten Path, his Neighbours ſoon will ſhew him that it is eaſy for him to reap a large Advantage from this Growth; and it will be the greater to him

him as he the more ſtrictly follows the ſeveral Cautions we have before given him, relating to the Choice of Seed; and other Articles, which few know; and even they too much neglect.

Thus much is in his Power, by following the common Practice, but if he will uſe the Horſe-hoeing Huſbandry, he will without doubt reap a vaſtly greater Advantage. This Method of Tillage is ſo new, that we have not in all Caſes an Opportunity of recommending it upon Experience; but in many wherein we have not had the Advantage of Trial, we may very ſafely propoſe it from Reaſon, and this is one of thoſe Inſtances.

The great Article in the Value of this Crop, is the Quantity of the Seed produced. This will be the more as the Plants are ſtronger and more flouriſhing; and there can be no doubt but they will be much ſtronger and better when they are raiſed by the Horſehoeing Method; for all Plants are ſo.

There are other Advantages of this Growth beſide the Seed of thoſe we ſhall ſpeak hereafter; but this of the Seed is the principal, and deſerves the firſt and greateſt Notice; the Crop being to be regulated according to that, not any other.

The Huſbandman having his Choice of the Common, or the Horſehoeing Huſbandry, may have either a great many Plants growing irregularly on his Field; or a ſmaller Number diſpoſed regularly and growing longer: it remains to conſider which of theſe will yield him the greateſt Quantity of Seed, and he may be certain this will be from the larger Plants.

In the irregular Manner of growing they ſtarve one another; and the Earth between them cannot be ſtirred and broken to any Depth to give them Nouriſhment: therefore they will be ſmall, and will ſhoot up in Height like Herbs raiſed under Shade; and will have few Branches. In the other Method they will be robuſt, and will ſpread every Way in Branches, and all theſe Branches will be full of Seed Veſſels. The Number will be vaſtly greater, and the Seeds will ripen to a much greater Perfection in them. This will happen becauſe the Plants ſtand at a ſufficient Diſtance; and becauſe the Earth can be turned up and broken by the Horſehoe between them.

In the common Way of ſowing, five Pounds of the Seed is uſually allowed to an Acre. In the Drill Method two Pound and a half will be full enough: and as to the Method of doing it, two Rows may very well be drilled at ten Inches Diſtance, with a five Foot Interval between them.

CHAP. LIX.

Of ſowing Coleſeed in the Drill Way.

IN the common Way of Management, Coleſeed is to be ordered much in the ſame Manner as Turnips. When it is got to ſome ſmall Height, Hoers are to be ſent into the Ground, whoſe Work ſerves very well to cut down the Weeds; and they may alſo thin the Plants where they happen to have riſen too thick, as they will always do in ſome Places from this irregular Manner of ſowing. To thrive well in this Way, they ſhould be ſuffered to ſtand at about ten Inches Diſtance.

In the ſame Manner when the Huſbandman ſhall think proper to raiſe this Crop by the Drill and Horſehoeing Method; they muſt be hoed when they have got a little Strength. In this Reſpect we need not tediouſly repeat the Particulars, the ſame Management ſhould be obſerved as in hoeing of Turnips, raiſed by this Huſbandry, which we have laid down at large in that Place.

The Weeds in the Partitions between the double Rows, are to be cut up with the broad Hand Hoe; and the Plants ſhould be at the ſame Time thinned till they ſtand but one every Foot and half, and theſe not oppoſite in the two Series, but one in each Row oppoſite to the Middle of the Space between two in the other.

When the Plants are thus cleaned out and thinned, let the Horſe Hoe or Hoe Plow be ſent in as ſoon as any Weeds appear in the Intervals. This will thoroughly deſtroy them, and well break the Ground.

This is to be repeated as often as the Weeds riſe, only obſerving this Caution, that at firſt the Plow tears up only the Middle of each Interval; and afterwards that it come nearer the Edges.

The Farmer need not be under any Uneaſineſs at the Diſtance at which his Plants ſtand, or at the Space of Ground that is left vacant between every Pair of Rows. They will yield the more; and he might even have them at greater Diſtances than we have named, without Danger of Loſs. They will grow robuſt in this Way, and as it is their Nature to ſend out on every Side a great many Branches: from theſe there will ſhoot others; and they will all be loaded with Seed Veſſels, ſo that moderately ſpeaking, and judging from what is ſeen in the Courſe of this Method of Huſbandry in other Kinds, one Plant may be expected to produce as much Seed as ſix in the common Way.

CHAP. LX.

Of managing the Crop.

WHEN the Coleſeed is ſown, there are only two Things neceſſary, the ſingling out the Plants to a proper Diſtance, and the keeping them clear of Weeds while young; for afterwards they will need no Care on that Head, the Plants are ſo ſtrong, and draw ſo much Nouriſhment, that nothing can live among them.

Which ever Method of raiſing the Crop be uſed, it is to be thus prepared for a good Growth; and this done, the Owner is to conſider, that it has more Uſes than one. Though the Seed be the principal Conſideration, it is not the only one; and the more Regard is to be

ſhewn

ſhewn to another, becauſe it comes in order of Time before it.

We have obſerved that this Plant is of the eatable Kind. As it does not grow ſo much into Root as the Turnip, its Leaves are more delicate. Sheep are very fond of them, and they afford a rich and wholeſome Nouriſhment. This, properly managed, is a great Article. The Sheep are ſupplied at a Time when they extreamly want Nouriſhment, and the Crop is far from being injured; on the contrary, it is improved by it. This therefore is to be conſidered as a very eſſential Part in the Management of a Coleſeed Crop, and we ſhall give the practical Huſbandman the Method of ordering it to the beſt Advantage.

Coleſeed having been ſown in the Beginning of JULY, ſhoots with ſome Strength; after a few Weeks keeps itſelf up during the Droughts of Autumn, and getting new Strength and Size in the Leaves from the Rains, which introduce the Winter, becomes in a Condition to reſiſt the ſtrongeſt Froſts. It ſtands well, and on every open Day or two, grows during the Depth of Winter; ſo that in JANUARY, FEBRUARY, and MARCH, the Ground is well covered.

The Leaves which now riſe, are of no real Uſe to the Plant in perfecting its Seed, which is to be done the ſucceeding Summer. If they grow very rank they rather are injurious, ſwallowing up too much of the Nouriſhment that ſhould go to the forming of the young Stalk, therefore they may be ſpared without Injury. Here is then a great Supply of Food for Sheep, at a Seaſon when Graſs is low, and it is extreamly wanted; and the Sheep are to be turned in to eat it without any Damage to the ſucceeding Crop of Seed.

There are thoſe who ſow Coleſeed in ſome Parts of NORTHAMPTONSHIRE for this Uſe alone; and it anſwers the Intent very well. They uſe the pooreſt Land for this Purpoſe, and on that, although the Plant would never grow vigorous and ſtrong ſo as to yield any profitable Quantity of Seed, it ſhoots up very well in Leaves.

In the proper Lands for this Growth, the Leaves at this Seaſon are much finer and ſtronger, and they may be eaten without Damage to the Crop.

There are thoſe who prefer the Cole Plant on theſe poor Lands for Food for Sheep, to the young Growth on ſuch as is richer; and they ſay it is more wholeſome; they are not without Reaſon, but their Experience on this Head ſhould not have led them to diſcard the Uſe of Coleſeed for feeding on rich Ground, but to uſe it with Diſcretion.

The Diſadvantage that attends the feeding of Sheep on the rank Growth of Coleſeed in rich Ground is, that it makes them ſwell. This is the ſame Conſequence that is taken Notice of in the feeding them on Clover, but it is eaſily remedied. 'Tis only at firſt that this rich Food takes ſo ill an Effect, and this may be prevented by proper Regulations. When the Sheep are firſt turned in, let it be toward the Middle of the Day; and an Hour before Sun-ſet let them be driven out again into a common Paſture. The next Day let them be turned in earlier, and driven out later; and ſo the third, fourth, and fifth: after this let them be juſt driven out at Night for two or three Days more, and let in again as ſoon as they will in the Morning. This will prevent the Effect of the Coleſeed at firſt, and being now hardened to it by a little Cuſtom, they may be left in the Fields of it altogether, and will thrive upon it excellently, without the leaſt Damage.

Under this Article of the Effect of Coleſeed on Sheep, it is proper to mention, that the firſt Shoots are not all that ſerve this Purpoſe. There is another Growth of them that is leſs rank, and that the Sheep love better; and which not being liable to affect them with any Diſorder, is to be truſted to them at their Diſcretion.

We ſhall in the next Chapter treat of the gathering of Coleſeed, and in an exact Method, we ſhould after that name the Shoots which riſe from the Roots and old Stumps of the Stalks; but theſe being a Food for Sheep, we ſhall treſpaſs upon Regularity, to avoid dividing this Article of their Feeding,

The Shoots of the Coleſeed after gathering the Stalks for Seed, are this mild, ſweet, and wholeſome Food we have been naming. Theſe grow very ſtrong when there has been Rain, but they are never rank or over-rich. Every one knows the Difference there is between the Cabbage and Coleworts; full grown Leaves firſt cut for the Pot, and the Sprouts that grow on the Stumps and Stalks after cutting; the Difference is juſt the ſame between the firſt Growth of large Leaves from the Coleſeed Plant, and the Shoots that riſe after the cutting down the full grown Stalks for Seed.

The Root of the Cole Plant is very ſtrong, it does not decay as many others do when the Seed ripens, but the Crop being cut for that Purpoſe, the Strength below ſoon ſhews itſelf: a great Number of Shoots riſe from the Part of the Stalk where it was cut off, and from the Joints between that and the Root; and ſome from the Top of the Root; ſurrounding the Stalk.

If the Coleſeed Plants have been cut up for Seed in the End of JUNE, theſe Shoots begin to appear about the ſecond Week in JULY.

They make but a ſlow Progreſs while the Weather is dry and ſultry, as it often is for a conſiderable Time at this Seaſon; but when ſome Rains come, they gather Strength and riſe apace.

Theſe all tend to Stalks, and would form ſo many new Plants for Seed, but that would not ripen well, nor would come in any Quantity; therefore it is not the Farmer's Intereſt to encourage it, and happily for him the Beginning of the Shoot is at a Seaſon when the Weather ſeldom favours its riſing to any Height.

Before theſe young Shoots get Strength for riſing up to Stalks, the cold Mornings come in, and ſtop them, ſo that they continue ſmall and low; but they grow buſhy from the Nouriſhment they receive from Rains; this is juſt what the Farmer deſires, and they grow more and more fit for the Sheep, and are in excel-

lent

lent Condition for them at the Time when they are moſt wanted.

We ſhall add to this general Account of the Coleſeed Sprout, ſuch particular Obſervations as may be uſeful to the practical Farmer.

In the firſt Place he muſt conſider the Condition of his Stock, and the Value of the Land on which this Crop is to grow: by theſe Articles he will be led to know how far it is proper for him to encourage, or ſuffer the ſtanding of it after the material gathering for Seed: for in ſome Caſes it may be not at all worth while, and in others very profitable.

If from the Circumſtances and Situation of the Ground, and his Stock, he find it adviſeable to continue the Growth, he will vaſtly increaſe it by a proper Management.

If it be ſown at random, according to the common Methods of Huſbandry, it muſt be hand-hoed juſt as the Shoots appear. Nature may be left to herſelf for a little Time, after the Stalks are cut down, and ſhe will give Strength enough to the Roots to make the Shoot; but then if a dry Seaſon follow, as is uſually the Caſe, theſe young Shoots will turn yellow, and threaten Decay.

In this Caſe it will be proper to ſend in the Hoers to clear the Ground between the Stumps, and the deeper they cut the better, for the beſt Work of this Kind is very ſuperficial and ſhallow.

The Weeds are few and ſmall that can ſtand upon a ripe Coleſeed Ground, ſo that the deſtroying theſe is but a ſlight Part of the Deſign in Hoeing: its great Advantage lies in breaking the Ground, and making it better receive and detain the Dews, therefore let it be broke as much as this ſlight Inſtrument will do it.

This Hoeing has alſo another Uſe, which is the cutting aſunder ſome of thoſe fibrous Roots that ſpread from the Bottom of the Stalk, under the Surface. Each broken Root in this Caſe will ſend out many new ones, and theſe will have a freſh broken Earth wherein to ſpread, and to draw that Nouriſhment with which the Dews and Rains enrich it. This we have ſhewn already to be extreamly effectual in the ſupplying all Plants with Nouriſhment, from the deeper and more perfect Method of Hoeing; and we ſee that in this ſlight and imperfect Kind, the Freſhneſs and free Growth of the Shoots immediately after ſhews the Benefit.

From this, which is the Method to be uſed for promoting the free and ſtrong Growth of the Shoots in the common Way of Huſbandry, we ſhall proceed to that more beneficial Way of doing it by the Horſehoeing Method, when the Plants have been ſown by the Drill. Nothing is of ſo great Service to this Crop, and indeed, as we have ſaid already, to any other, as the breaking the Ground while the Plants are growing upon it; but this Advantage is always the greater, as the breaking the Earth has been done the more perfectly.

We have adviſed the Farmer to conſider the particular Situation of his Farm, his Stock, and the Value of his Land, in order to determine whether or not he ſhall continue to raiſe Coleſeed upon the ſame Piece of Ground. If he reſolve to do this, we have ſhewn him how it is to be effected in the common Method, by promoting the Growth of the young Shoots, but this is only for a Time: on the contrary, in the Horſehoeing Method, the ſame Piece of Land, if the Farmer think convenient, may bear Coleſeed for ever, and that in a very beneficial Method, not only for the Crop, but the feeding.

In this Caſe we are to ſuppoſe the Coleſeed raiſed in double Rows, with proper Intervals between Pair and Pair, as we have directed. It is now we will ſay, June, the Plants are vigorous, and they will ſoon be ready for cutting. The Method of doing this we ſhall ſhew in the ſucceeding Chapter.

The Intervals afford an excellent Space for the Management of the Plants when cut, and as ſoon as they are cleared off, and the Seed thraſhed out, they are to be plowed up with the Horſe Hoe or Hoe Plow. This deep plowing furniſhes the Roots of the old Plants with abundant Nouriſhment, ſo that they ſhoot up the Sprouts before-mentioned in vaſt Abundance, and with great Strength; and at the ſame Time double Rows of freſh Seed may be ſown in the Middle of each Interval for a ſucceeding Crop. In this Caſe both will flouriſh greatly. The Leaves from the Roots of the new ſown Plants, and the Sprouts from the Stumps of the old ones; theſe laſt will grow with a particular Freſhneſs and Vigour, becauſe all the working of the intermediate Earth for the ſowing of the new Crop, will be ſo many Additions of Tillage upon Tillage for them; and the Roots of the Seedlings will not ſpread ſo far at firſt as to interfere with them. Thus they will grow and flouriſh together during the Remainder of the Summer, the Autumn and the Winter; and in early Spring, there will be a double Supply of Food for the Sheep.

In the End of March when the Sprouts are well eaten down, for the Sheep having their Choice of both, will be fondeſt of them, they are to be plowed up by the Hoe Plow; and the Places where they ſtood are to be made the Intervals for the new Crop.

This new Succeſſion will by the Time juſt mentioned, have ſpread out their Roots in Abundance toward the Places where the old Crop grew: the plowing up of the Roots of that Crop, will break and cut off thoſe of the young Plants; and this Earth being thoroughly broken by the ſame Operation, will be rendered full of Nouriſhment, and ready to receive thoſe innumerable new ones that will grow from the broken Ends of the old. Thus the Ground will be by the ſame Operation cleared and tilled, and the Crop will grow in a ſurprizing Manner; much better than any other Way. The Plants will be very vigorous, large, and full of Seed; and the Crop will be ripe and ready for cutting, a Fortnight ſooner than that raiſed the common Way.

In this Manner, only repeating the ſame Management on every new Occaſion, the ſame Piece of Land may be made to yield a continual Succeſſion of Coleſeed Crops, without fallowing; and, if it be tolerably good Earth, without Manure.

One thing there is, concerning which we muſt caution the Farmer who ſhall have the Senſe and Spirit to raiſe Coleſeed this Way, which is, the guarding againſt the too great Luxuriancy of the Crop of Sprouts. We have ſaid they advance ſlowly during the Summer, in the common Way, and that it is to his Advantage, for otherwiſe they would run up to Stalk, which is not his Intereſt, as not the Seed but the Leaf is to be uſeful to him the enſuing Spring.

If Rains happen ſoon after the cutting the old Plants, this Accident of the new Shoots running to Stalk is apt to happen in the common Way of Huſbandry, becauſe more Nouriſhment is ſupplied by the Moiſture than is wanted in the Leaves; and the ſame Thing happens much more certainly from the deep plowing the Intervals, when the Coleſeed is raiſed by the Drill and Horſehoeing Method: therefore if Rain falls ſoon after, or if the Shoots are over rank without that Aſſiſtance, as will often be the Caſe when the Ground is tolerably good, let him go round the Field himſelf up and down every Interval, or employ ſome truſty Perſon to do it, and with his Thumb and Finger knip off the Top of every Shoot that is running up to Stalk. By this the Advance upwards, which is of no Uſe, will be ſtopped, and the ſame abundant Nouriſhment which was ſupplying the Growth that Way, will furniſh new Shoots upon the Sides of the firſt. So that in a Field of this Plant, tolerably good as to Soil, and managed in this Manner, there ſhall ſtand, as it were, a Foreſt of green low Buſhes without one Stalk, riſing toward flowering: for when ſuch as were moſt forward are nipped this Way, the cold Weather coming on checks them, and all the Nouriſhment they draw from that abundant Reſource of Tillage, will go to enlarge the firſt Leaves and form others. A little Obſervation of what paſſes in the common Courſe of Nature on other Occaſions, will ſhew the Farmer how eſſential and material a Point it is to nip theſe riſing Stalks. They will be of no Uſe as to Seed, that we have ſhewn him already.

It is not a Crop of Seed he now wants, that he has had before, what he in this Caſe deſires to have is a Supply of Leaves, for the Food of his Cattle; and the Merit of this Crop is, that theſe Leaves be numerous and freſh, and full of Juice. Let him obſerve what happens to the Leaves of other Plants: when they have all the Nouriſhment to themſelves, they are numerous, freſh, and full of Juice; but as ſoon as the Stalk has got to any Height, and the Rudiments of Flowers and Seeds appear, this being the great Intent of Nature in the Oeconomy of all Plants, the Nouriſhment taken in by the Root all goes there. The Leaves that were freſh, juicy, and green, become withered, dry, and yellow, the older ones fall off; no new ones grow in the Place, and in fine all decay, and the Stalk alone remains riſing naked from the Root.

The Uſe of the Leaves which riſe firſt from the Root, is of the ſame Kind with that of the gaudy and beautiful Parts of the Flower. We have obſerved before, that although theſe ſeem the Perfection, and greateſt Beauty and Excellence of the Plant, they are intended only to ſhield and defend the little obſcure Rudiment of the Fruit, or Seed Veſſel, that ſtands in their Centre; and in the ſame Manner that fine ſpreading Shew of Leaves, which firſt riſe from the Root of a Plant, are in Reality of no other Uſe than to ſecure and preſerve the little Rudiment of the Stalk, which is hid in their Centre.

We ſee that as ſoon as the Duſt from the little Buttons in the Flower has impregnated the Rudiment of the Fruit, the gaudy Leaves decay and fall off, the Nouriſhment being all conveyed to the uſeful Part, the Fruit or Seed Veſſel; and in the ſame Manner, as ſoon as theſe Leaves have defended throughout the Winter the young Bud of a Stalk, and that by the Heat of the Spring Sun begins to riſe in Height, and ſhew its Buds for flowering, all the Nouriſhment is conveyed to it. The lower Leaves have done their Buſineſs, and they fade and periſh.

The Caſe is juſt the ſame in the Shoots from the old Stumps of Coleſeed, as in the Leaves from the Root at the firſt ſowing. The Leaves that riſe from the Top, and from every Joint of the old Stump, have the Rudiment of a Stalk within them. This is the Purpoſe of Nature, but it is the Farmer's Buſineſs in the preſent Inſtance, to check it. When it riſes the Leaves will fade, but ſo long as it is kept down, whether that be done by Art or Accident, all the Nouriſhment intended for it by Nature, will be given to the Leaves. This is the Reaſoning upon which the Practice of nipping off the Buds of the Coleſeed Sprouts is founded. We would have the Farmer underſtand all he is adviſed to practiſe.

CHAP. LXI.

Of the gathering of Coleſeed.

TOward the End of June the Coleſeed Plant, in whatever Way it have been raiſed, will be fit to cut. The Huſbandman muſt therefore keep his Eye upon his Field very carefully toward that Period; for it is of the utmoſt Importance to him to ſeize it when it comes. No Day of the Month, or other preciſe Time, can be named for the gathering this Crop, becauſe the Differences of Soils and Seaſons promote and retard its ripening; and even the Variety of Management, or the Age of the Plant, may make ten Days or a Fortnight Difference in the ripening in two Fields of the ſame Soil in the ſame Year. We have told the Huſbandman about what Time he is to expect it; and ſhall add the Signs by which he ſhall know that it is fit for Harveſt. One Caution we muſt give him withal, that as the Soil and Method of Culture may make a very great Alteration in the Time of ripening, he muſt be upon the Watch accordingly, expecting it earlier by a Fortnight in rich Soils and the moſt careful Conduct, than he need in poor Land in the common Way. It will be in vain that we lay down the Signs of its ripening, if he ſlips the Time.

We have obſerved that the Coleſeed Plant has ſmall Flowers on the Tops of the Stalks and Branches, which when the Leaves fall off are

ſucceeded by Pods. As the Flowers that opened firſt are thus followed by the Seed Veſſels, other Flowers open upon the Tops, which ſhoot up continually higher and higher. Thus, when the Plant begins to flower, nothing is ſeen but a little Button or Tuft of Buds at the Top of the Stalk, and of every Branch, with one or two Flowers opened or opening upon it; but when it has been ſome time flowering the Aſpect differs, for then the Branches having lengthened, from the Time of their beginning to flower, all that Part of them which was the Top, and where ſucceſſively the former Flowers appeared, is covered with Seed Veſſels; thus each Branch terminates in a Spike or Seed Veſſels a Foot or more in Length, with a few Flowers at its Top.

The Quantity of Seed is the Riches of the Crop, therefore it would appear at firſt Sight, that the longer the Plant ſtood, ſo long as it continued flowering, the more advantageous would be the Growth, but there are Limits to this Encreaſe, beyond which all is Waſte.

The Courſe of Nature is to ripen theſe Seeds, and then ſhed them upon the Ground for producing the Plant again: therefore when ripe the Pods open of themſelves, and the Seeds are loſt. This no Art can prevent; and for that Reaſon the Time is to be watched when any of them begin to open, and that is the exact Period for gathering.

When a new Flower is formed, the Rudiment of the Pod from which the laſt fell, is but ſmall; it continues to encreaſe in Size before it begins to harden, or properly ſpeaking to ripen, ſo that ſeveral ſucceſſive young ones are left by the Flowers before any one is ripe. This is the Occaſion of the Length of the Spike of Pods, while all are yet entire; but when they begin to open let the Huſbandman be ſpeedy in gathering, for he will deceive himſelf very much if he imagine it as well to let it alone awhile, ſuppoſing the new formed Pods at the Top of the Stalk will make Amends for the old ones that are loſt at the Bottom: the loweſt Pods are the faireſt always, and three of the young ones will not ſupply the Place of one of the lower.

The Farmer now underſtands the Period whereat his Crop is to be gathered; and it will be eaſy for him to judge at Sight when it is about to arrive at that Condition.

The Length of the Spikes of Pods is one obvious and familiar Token, while they are ſhort the Crop cannot be fit to gather, becauſe, while they are in that Condition there are but few of them, and none of theſe are ripe.

When theſe Spikes have got a conſiderable Length, their Colour is to be regarded. The Pods while young are always green, as they grow toward Ripeneſs they loſe that Colour; at firſt they become pale, then yellowiſh, and laſtly browniſh. The whole Spike, while very young, is green.

When ſome of the Pods approach toward Ripeneſs they change Colour, and the Greenneſs is only ſeen at Top; when, upon a curſory View, there are ſome found to grow browniſh at the Bottom, and thoſe in the Middle are yellowiſh or pale, thoſe at the Top only being green, then the Time of gathering is at Hand. It is the Intereſt of the Owner to let them ſtand ſo long as all are ſafe, but no longer. He is therefore now to look into the Field once or twice every Day, in a more ſtrict Manner. He muſt examine the bottom Pods of the ripeſt Spikes; ſo long as theſe are cloſe all is ſafe; but as ſoon as ſome of them begin to open the Time of gathering the Crop is come, for after this every Hour's ſtanding will be attended with Loſs.

The beſt Method of cutting Coleſeed is with a ſtrong Sickle, in the ſame Manner as Wheat is reaped: but this muſt be done carefully. There is no Part of the Farmer's Occupation that requires more expert and honeſt Labourers than this. The Stalks are pretty thick, and by that Time the Seed is ripened thus far, they have loſt their juicy Condition, and are grown hard and ſticky. They are not eaſy to be cut, and yet that muſt be done evenly, and with little ſhaking. A great deal of Care is to be taken, that the Sickle goes eaſily through them, and when ſeparated from the Root they muſt be laid gently down in Handfuls, that they may dry.

About one third Part of the Seed is ripe at the Time when the loweſt Pods are ready to open: in the lying expoſed to the Heat of the Sun at this Seaſon, more than another third hardens, and becomes good; ſo that above two thirds of the whole Quantity of Pods yield good Seed, and this is all that can be expected; for if the Farmer were to ſtay for the ripening of the other third, while growing, he would loſe the Seed from the lower Pods, which is much more valuable; and the Seed is of a ſufficient Growth to ripen or harden in the Sun after the Plant is cut down.

In the common Way of ſowing Coleſeed, 'tis difficult to lay the Handfuls well to dry from the reaping, and a great deal of the beſt Seed is loſt for want of this Advantage; but in the Way by drilling all will be eaſy, and there will be no Danger of Loſs, for the Intervals will ſerve excellently for ſpreading the Plants.

When the Crop has been once laid on the Ground it is not to be ſtirred till dry, for the Seeds in the lower Pods are ſo looſe, that they will ſhake out with the leaſt Motion, and be loſt. What is required from this Expoſure is, to dry and harden them, and they will get this ſufficiently by lying tolerably thin, without being moved. If the Weather be very hot the Buſineſs is done the ſooner, if otherwiſe ſomewhat more Time is required, generally from ten Days to a Fortnight proves ſufficient. The Proof that they are dried enough is, when the Pods toward the upper Part of the Spikes open eaſily, and the Seeds in them are hard.

CHAP. LXII.

Of thraſhing the Plants, and the Uſes of the Seed.

WHEN the whole is in this Condition, nothing is required but to get it to the Barn, and thraſh it. In Lincolnshire they ſave themſelves a Part of this Trouble, by thraſh-

ing it in the Field, they ſpread a large Sheet upon a level Part of the Ground, and lay a Quantity of the Herb on it: a little thraſhing does to diſlodge the Seeds, which are already looſe and moſt of them in Danger of falling out of their own Accord. I have ſeen this practiſed without much Loſs, but it is an irregular and awkward Method; it leaves the Farmer's Produce, after all his Toil, very much at the Mercy of the Winds, and cannot be performed ſo well as in Doors.

The Method I would therefore recommend to the Huſbandman, if the Ground be any thing near Home, is this, let a Parcel of large Sheets be ſpread in the Field, and the dried Stalks carefully taken up in their Bundles, and laid on them. Each Sheet will hold a great deal this Way; for though the Parcels muſt be very gently moved to the Sheet, they may be preſſed hard, and handled roughly there; for what Seeds fall out will be ſaved.

When the Sheets have as much in them as they will hold, the Edges and Corners are to be gathered in and faſtened, and the ſeveral Parcels are to be carried to the Barn: there they are to be thraſhed with a careful but light Hand, that all the Seed may be got out, and as little of it as poſſible bruiſed, for it is tender and eaſily hurt, eſpecially when freſh.

After it is ſeparated from the Refuſe that was mixed among it in the thraſhing, it muſt be ſpread on a Floor pretty thin, and turned often till it is thoroughly dry and hardened; for otherwiſe, when put up, it will quickly grow damp and mouldy.

The Seed thus prepared for keeping is alſo in a better Condition for immediate Uſe, than when too green: the Farmer may ſell it, or ſend it to the Mill on his own Account to be ground and preſſed for Rape Oil, the Sale of which is certain, and the Price, conſidering the Charge, tolerably high. If the Seed be ſold as ſoon as thraſhed and dry, it brings from eighteen to two and twenty Shillings a Quarter, and the Produce at an Average in the common Way of Management, and upon middling Ground, may be reckoned at five Quarters to an Acre: much more Advantage may be made of it, if the Farmer will have the Oil drawn himſelf; and in the Method we have propoſed by the Drill and Horſe-hoeing Huſbandry, it will be eaſy for him at any Time to double his Profits: in many Caſes, taking all the neceſſary Care, and making the moſt of his Produce, he may make it treble.

We have obſerved that in the new Method of Huſbandry, the ſame Piece of Land may be made to bear Coleſeed ever ſo many Years in Succeſſion. According to the vulgar Practice the ſeveral Kinds of Corn may be ſown after it. In Northamptonshire, where the Land is rich, they find Coleſeed a very good Preparer of it for Barley or Wheat; in Lincolnshire, where it is not ſo good, they ſow Oats after it very profitably.

The Uſe of the Coleſeed is not over when the Oil has been preſſed from it. The Cakes that remain are a large Quantity, and as the freſh Leaves feed Sheep, theſe in a proper Method of giving them, turn to a very good Account for feeding of Cows. In Winter this is an excellent Food for them, for keeping them in Heart and Strength, at a Time when other good Food is ſcarce.

Calves are alſo to be fed with Coleſeed Cakes very profitably, but that in a particular Manner. After the Oil is preſſed out as clean as the common Practice can obtain it, there ſtill remains ſo much of it in the Cakes, that when they are beat to Powder, and mixed with hot Water, they make it white and milky, in the ſame Manner as ſweet Almonds beat up with Water make an Emulſion. This is the Way of giving it to Calves, and it proves a very rich, wholeſome, and ſtrengthening Food. Calves may be fed with this from three Days old, till they are fit to eat Graſs or Hay.

In Flanders and Holland, where Coleſeed is raiſed, and its Oil preſſed in great Quantity, and to great Advantage, they conſtantly make both theſe Uſes of the Oil Cakes: it is ſurprizing that in many, nay in moſt Parts of England, where they raiſe this Crop, they know no other Uſe of the Cakes than as firing. In Lincolnshire they heat Ovens with them, while they want Winter Proviſion for their Cows. In ſome few Places, and but few, they have got into the Method of giving the Cakes in Water to their Calves.

There are many Reaſons to wiſh this Species were more cultivated than it is in England, but there is but poor Hope of that being brought about, when thoſe who do raiſe it know but a ſmall Part of its Management, or its Advantages.

CHAP. LXIII.

Of Liquorice.

HItherto we have treated of Articles known to be raiſed by Huſbandmen, in different Parts of the Kingdom, and familiar by Name among Country People; ſo that the Farmer who never had before thought of raiſing them himſelf, yet knew others did ſo: here we mention one which, being leſs common in the Profeſſion, may make ſome of the common Practiſers of Huſbandry wonder at its being added to the Liſt of Things recommended to them for Culture. They know Liquorice by Name, and they are ſenſible that it brings a large Price at the Druggiſts: much of it is imported from Germany, and other Parts of Europe, but we can acquaint thoſe Farmers who have not been in the Way of knowing it, that very conſiderable Quantities of this valuable Root are raiſed in Fields, in ſome Parts of England, and may be in many others. We have all along obſerved, that great Gains are to be made in Huſbandry by going out of the common Road, and this is one of the Inſtances.

We would not adviſe the Farmer to let alone his common Occupation, or to neglect the uſual Articles of his Profeſſion; on the contrary, we have made it an eſſential Part of our Work to inform him of every Method of managing them to the beſt Advantage; but with the Cultiva-

tion

tion of theſe we would have him keep his Eyes open to that of other Things: particular Soils and Situations ſuit particular Growths, and we would have him a Maſter of the ſeveral Articles in his Buſineſs, uncommon as well as common; that when he has an Opportunity of gaining conſiderably, by adding ſome new Species, he may not over-look the Advantage. It is in this Light we propoſe Liquorice to his Conſideration; and having thus far explained the Intent of naming it in this Place, ſhall proceed to acquaint him with the Nature of the Plant, its proper Soil, its Culture and Advantages.

The Root of the Liquorice Plant is a Yard long, and as thick as a Man's Thumb. It is ſoft but very tough, brown on the Outſide, and yellowiſh within: it is full of Juice, and though not eaſily broken, may be beat out into a Kind of thready Subſtance: its Taſte is very ſweet and pleaſant, it ſpreads and encreaſes naturally in the Ground, and is leſs in Danger of Accidents than moſt other Roots.

From this Root riſe the Stalks, which are tall, firm, and tough, they are a Yard or more in Height, they have but few Branches, they are of a brown Colour, and covered with a Kind of clammy Moiſture, ſo that they ſtick to the Fingers when touched.

The Leaves are ſomewhat like thoſe of the Tare, each being compoſed of a great many ſmaller ones, placed on the two Sides of a Stalk, or middle Rib.

The Flowers are alſo of the Form of thoſe of the Vetch or Tare, but ſmall and inconſiderable; and they are ſucceeded by Pods, which are ſhort, flatted, and upright.

The Flower of the Liquorice ſtands in a ſmall green Cup, which remains after it is fallen, and encompaſſes the Bottom of the Pod. This Cup is compoſed of a ſingle Leaf, which is hollow at the Bottom, and toward the upper Part is divided into two Lips: the upper Lip is again divided into three Parts, two narrow and pointed at the Sides, and the middle one broader and nicked in the Middle: the under Lip is undivided, and is narrow and pointed. This is the Cup which receives and ſuſtains the Flower. The Flower itſelf is compoſed of four Leaves, in the Manner of all the Pea and Tare Kind. In the Body of the Flower there are ten Filaments, one ſtands alone, and the other nine in a Cluſter; at the Tops of all theſe there are round Buttons, and in the Centre of theſe riſes a ſmall Lump, which is the Rudiment of the Fruit or Pod; this is buried in the Cup, and ſends out a long Filament pierced at the Top, to receive the Duſt from theſe Buttons for impregnating the Seeds.

When the Flower has fallen off, this Rudiment by Degrees enlarges into a ſhort, flat, and ſharp Pod, in which are a few Kidney-ſhaped Seeds. There are two Kinds of Liquorice beſide the common, diſtinguiſhed the one by having hairy, and the other prickly Pods, but theſe are not worth the Farmer's Notice; the Smoothneſs of the Pod diſtinguiſhes the right genuine Liquorice uſed by the Apothecaries, as does alſo the Bigneſs, Juicyneſs, and fine Taſte of the Root; the others have ſweet Roots, but they are harder and leſs pleaſant.

The common Liquorice is a Native of GERMANY, FRANCE, SPAIN, and ITALY; we have it not wild in ENGLAND, but being natural to Climates ſo much reſembling our own, it grows with us in Perfection.

It was very well known to the Antients, who called it Adipſos, becauſe it conquers both Hunger and Thirſt. THEOPHRASTUS mentions it under the Name of the SCYTHIAN Root, SCYTHIA being the firſt Country where it was known to be cultivated. It ſerved theſe People by Way of Nouriſhment, they would live a long Time upon this Root and Mares Milk Cheeſe, without ſeeking after any other Food. It is raiſed in ſome Parts of YORKSHIRE, NOTTINGHAMSHIRE, and SURRY with us; and may be introduced in many other Places, to the great Benefit of the induſtrious Planter.

CHAP. LXIV.

Of the proper Soil for Liquorice.

ALMOST all Plants thrive beſt in a rich Soil, but Liquorice will not grow in any other. One Requiſite more there muſt be in the Land for this Purpoſe, that is, the Soil muſt run deep. The thriving of Liquorice depends altogether upon the free Depth of the Mould, and its Length of Root, which is the great Advantage cannot be expected in any other.

We expect to ſee the Root a Yard or more in Length, and it muſt have free Paſſage, otherwiſe it will not grow ſtrait; this Regularity of Shape is not only a great Beauty, but a real Advantage, for the crooked Roots are never ſo tender and juicy as the others, nor do they ſo ſoon arrive at their due Growth.

The proper Ground for Liquorice is that which has a deep Coat of mellow Earth, a black Mould that begins directly under the Turf, and runs three Spit deep, without any great Mixture of other Matter in the Way. This is the beſt natural Soil for this valuable Plant, but there are others which will do by Nature, and others yet that may be ſo prepared by Art, as very well to anſwer the Purpoſe.

After this fine black Mould the next Soil in Nature is a deep rich Loam, that has not much of the Clay in its Compoſition, and has a good deal of fine Garden Mould among it.

The third natural Soil that we ſhall name as fit for this Plant, is the deep, warm, ſandy Kind, which is not barren, but with its Lightneſs and Warmth has ſome Richneſs.

In all theſe Soils the Depth ought to be at leaſt a Yard, before there is any hard Bottom, and that muſt be examined; for if it prove a Clay the Liquorice will never thrive, becauſe of the Coldneſs and Dampneſs that naturally attends ſuch an under Stratum, the wet lodging upon it and ſtarving the whole Soil.

What the Liquorice requires for perfect thriving, conſiſts in four Articles, Depth to penetrate, Lightneſs in the Soil that it may make its Way eaſily, Warmth to promote its Growth, and Richneſs to ſupply it Nouriſhment. Theſe Advantages it enjoys in various Degrees,

in the ſeveral natural Soils we have named, for no one of them has them all in Perfection; and therefore it may be poſſible by Art to provide a Soil for the Growth of Liquorice, which ſhall be better than any of theſe.

To explain this by Particulars. In the mellow Earth or black Mould, there is often Depth and Lightneſs enough, and there is always Richneſs to ſupply it Nouriſhment; but then this Soil is apt to be cold: there wants therefore the fourth Article Warmth, to promote its ſpeedy Encreaſe in Bigneſs. In the ſame Manner in ſome of the loamy Soils there is Lightneſs, Depth, and Warmth, but there wants Richneſs; and finally, in the ſandy there is Depth, Lightneſs, and Warmth in the greateſt Degree, but there wants Richneſs and Nouriſhment. The Effect of theſe ſeveral Advantages and Diſadvantages in the Soil, for the Growth of Liquorice, I have regarded in the Obſervations I have made on the Places where I have ſeen it grow.

Thus in YORKSHIRE, where the Soil is a mellow rich Earth, as about POMFRET, the Liquorice is very large and juicy, but it grows ſlowly; in NOTTINGHAMSHIRE the Soil is loamy, and the Liquorice grows moderately, but is inferior to the POMFRET Kind; and in SURRY, where the Soil is ſandy, the Root grows quick, but it is meagre, dry, and poor, it never has the fine juicy Texture, or rich Taſte of the YORKSHIRE Kind.

From theſe Advantages and Defects in the Plantations of others, the judicious Farmer will find the Way to make the beſt Profit of his own, by adding what is wanting in each, and avoiding what is amiſs. It is to be obſerved, that in the preceding Obſervations we ſpeak of theſe ſeveral Soils left to Nature, for when they are manured they are changed; and it is impoſſible to deſcribe the Soil of any Place, as altered by the various Means of Culture.

To theſe ſeveral Grounds for the Service of this Article, we are to add the made Soils about LONDON, where there is a great deal of Liquorice raiſed in the Grounds of Planters to a conſiderable Profit. This is large and juicy, but it is not ſo good as the YORKSHIRE Root, it is leſs tough, and is more ſubject to Accidents, nor has it the fine yellow Colour, or true rich Taſte of the beſt Northern Liquorice. It will grow mouldy if laid up in damp Sand, whereas the YORKSHIRE Kind will be perfectly well in that Manner for a long Time; and when beaten out for Uſe the Threads are more wet, and as it were rotten; they have not the ſtringy Toughneſs of right Liquorice: the Plant is the ſame in all theſe Conditions, 'tis the Soil only that makes the Difference. The Liquorice of SURRY is ſtarved, that of NOTTINGHAMSHIRE is but half nouriſhed, and that raiſed in Gardens about LONDON is over-ſupplied with Nouriſhment, and that is of too rank and moiſt a Kind: the ſame is the Caſe with many other of the Products of theſe common Gardens, though leſs regarded.

We ſee by the ſeveral natural Soils, and their Effect, and by that of the made Ground about LONDON, that each of the others may be improved; conſequently that a made Soil may be better for Liquorice than any of them, but we ſee at the ſame Time, that the Garden Ground about LONDON is not the right Kind; what the careful Huſbandman is to learn therefore from theſe ſeveral Obſervations is, that there is an eaſy Way of mending any natural Soil, for the Production of Liquorice; and that whatever his Ground naturally be, he may convert it into a proper Sort by additional Mixtures.

The ſeveral Defects and Faults of thoſe Soils, on which Liquorice is propagated in different Counties of ENGLAND, are ſo oppoſite to one another, that whoever has conſidered the Principles laid down in the Beginning of this Work, will find it is very poſſible, and very eaſy to improve any one of them, by a Mixture of the other; and conſequently, that if he have a Soil of the Nature of any one of theſe, he may improve it and encreaſe his annual Produce greatly, by mixing with it ſome other Soil of the Nature of one of the others.

Thus if he have a mellow Earth, or deep black Mould, of the Nature of the POMFRET Kind, he will know that Liquorice will grow fine, but ſlowly with him; therefore let him, when he digs up his Ground of this Kind, mix with it a good Quantity of Sand, ſuch as compoſes the principal Part of the Soil in SURRY; and this will make it grow quicker, while there is yet enough of the natural Richneſs of the Earth to feed it very well. In the ſame Manner, if his Soil be loamy, as that of NOTTINGHAMSHIRE, or ſandy, as that of SURRY, let him add mellow Earth to it, and he will make his Liquorice rich, while the natural Condition of the Ground continues to haſten its Growth.

He ſees in the ſame Manner the Effect of Manure about LONDON, where it is uſed in great Plenty; and he finds it has Advantages and Faults. The Advantages it poſſeſſes are owing to the Dung that is uſed, and the Faults are owing to the Rankneſs of that Dung, which is too much for a Root of this Kind.

Having laid thus before him the Reaſons of every thing he is to do, I ſhall add by Way of Example, what I have myſelf practiſed with great Succeſs, for the raiſing this Species, and lay down what I am convinced is the very beſt Method of improving and preparing a Soil for it. I ſhall limit it to the ſingle Inſtance of my own Experience, but the Effect being ſeen the Steps may be varied according to Occaſion.

I had a Field of an Acre, or ſomewhat leſs, the Soil was a good light Loam, but not very rich, and it ran near three Foot deep, with a firm light Gravel at the Bottom. It came into my Mind to try this for Liquorice, and I prepared it in this Manner; I threw on thirty Load of very old and well rotted Dung; and forty Load of Mud, from the Bottom of a River that ran near it. All this I plowed deep in, and repeated this Operation till it was thoroughly mixed with the natural Soil. This had before been of a yellowiſh or Orange Hue, and ſandy, but when this Addition was well wrought in it looked black, and broke mellow, in the Way of Garden Mould. This Field bore the fineſt Liquorice I ever ſaw any where, and I have examined moſt that is raiſed in ENGLAND. As to the Manner of planting it, that will be delivered in the following Chapter.

CHAP. LXV.

Of planting Liquorice.

LIQUORICE, though raiſed in Fields, requires a Sort of Garden Culture. The Spade is a much more proper Inſtrument for preparing the Land for its Reception, than the Plow; for it requires to be broke and rendered fine, to a Depth that the Field Inſtruments can never reach.

There is this Comfort however to the Huſbandman in Reſpect of it, that if the Land require a very expenſive Tillage, the leſs of it ſerves; a few Acres will yield a vaſt Produce in this Root, and the Price is ſo much greater than that of moſt other Things he can raiſe, that there is no Reaſon to grudge the Charges.

To make the Ground ready for receiving of Liquorice. It is firſt to be dug up carefully, but even this is not to be done in made or improved Soils, till the Additions have been thoroughly blended and rotted in the Ground.

Thus ſuppoſing an Earth improved as in the laſt Chapter, by the Addition of rotten Dung and Mud, theſe are to be plowed in toward Autumn, and the whole is to be broke again once or twice during the open Weather in the ſucceeding Winter, and ſo left to mellow; for the Dung will not otherwiſe thoroughly break and mix with the Soil. If it remain in Strings or Cakes, it will not be eaſily broke by the Spade; and if it remain whole, will break in upon that perfect Lightneſs of the Earth, which is ſo eſſential to the Growth of Liquorice. For if there be the leaſt Thing to obſtruct the Paſſage of the Roots, they loſe their Straitneſs, and after that they never thrive.

When the Ground has lain thus the Remainder of the Winter, let it be dug in the following Spring with particular Care, and in peculiar Manner. Let the Labourers be ſent in about the Middle of February, and let the Maſter's own Eye be over them, or that of ſome truſty Perſon in his Stead. They muſt dig every Part of the Earth thoroughly, no leſs than three Spits deep; and as they lay it, muſt carefully break every Lump, though but ſmall, that the Ground may be ſmooth and level at the Surface, and be in a Manner as fine as Sand all the Way down. This will never be honeſtly done without great looking after, and it is very eſſential that it be ſo done; the Expence is conſiderable, but the Profit anſwers; and of this the Huſbandman may be perfectly aſſured, that by every Shilling he would ſave in this Work, he will loſe ten in the Crop.

When the whole Piece of Ground is thus prepared, the Liquorice is to be planted; and in this the ſame Care and Caution are neceſſary as in the reſt, for the leaſt Omiſſion, or the leaſt Careleſsneſs, will be attended with Loſs. The firſt Care in this Reſpect is, the Choice of proper Sets or Plants; and the ſecond is, the placing them properly in the Ground.

For the Choice all depends upon their being in good Condition, and having a good Bud, or as the Planters call it, an Eye. They are to be got from the Seeds, or the Heads of the old Roots; and their beſt Length is a Foot, or thereabouts.

The good Condition of theſe will be ſeen by their Soundneſs, Freſhneſs, and clean Surface: and the Strength of the Bud or Eye, is an Article in which none can be deceived.

'Twill be toward the Beginning of March, by that Time the Ground is thus perfectly prepared, and the Sets are choſen, then they are to be planted in the following Manner.

Let there be got ready a Gardiner's Line, of ſuch Length as to reach croſs the Ground if ſmall; if larger, it may be removed from Diſtance to Diſtance, a Couple of Sticks ſharpened at one End, and a Ball of thick Cord is all that is needful for this Purpoſe. Beſide the Line, there is to be a ſetting Stick, which may be of any convenient Length at Pleaſure; but it is beſt to have it of a certain Dimenſion in this Reſpect, that it may ſerve as a Meaſure; and for this Reaſon I adviſe it to be juſt a Foot and half long, with a Handle like that of a Spade, and a point Head, with a ſquare Piece of Iron in the Manner of a very large Spike, hollow'd at the large End to receive the Point of the Wood.

Theſe Things being ready, let the Stake to which one End of the Line is faſtened, be ſtuck into the Ground a Foot from the Edge of the dug Part, and the Line let looſe, that the other Stake may be carried to the other End of the Ground, or as far as the Line will by its Length permit; and then it muſt be ſtuck into the Ground, drawing the Line tight, at the ſame Diſtance from the Edge of the prepared or wrought Part. Thus there will be a ſtrait Line drawn along the Skirt of the Ground, within a Foot of the raw Earth.

Let the Planter now taking his Sets in his Apron, and the ſetting Stick in his Hand, begin to plant, placing the firſt Set at half the Sticks Length from the Edge of the Ground. When he has ſet this, let him meaſure from it along the Line, the Length of the ſetting Stick, and then plant another, and ſo on to the End. This is very familiarly and eaſily done, and the Manner is this.

Let the End of the ſetting Stick, which is pointed with Iron, be thruſt into the Ground, and preſſed till near the whole be in; let it not be ſtirred about, but juſt enough to make an Edge, that the Earth may not fall together. The ſetting Stick being gently drawn out, there will remain an open Hole of about ſixteen Inches deep. Into this a Set of the Liquorice is to be put, thruſting it carefully and evenly in, till the Head of it where the Eye or Bud is, be one Inch beneath the Surface: then the bottom End will be about the Bottom of the Hole, and a little Mould being drawn over the Top, the Set is compleatly well planted.

One being ſet in the reſt is very eaſy. The ſetting Stick is to be laid along the Line, its Point juſt at the Head of the Set, and its other End marks the Place where the next is to be planted: the Length of the ſetting Stick being a Foot and half, and that being the moſt

advantageous Diſtance at which Liquorice can be placed in the Row.

This ſecond Set is to be planted exactly in the ſame Manner as the firſt, and ſo on till there be a Row planted all along the Line.

When one Row is thus planted, the next is to be ſet into the Ground. As the beſt Diſtance for Liquorice is to plant it in Rows at a Foot and half: ſo the beſt Diſtance of the ſeveral Rows one from another, is two Foot and a half; and in theſe they are beſt ſet not directly oppoſite one to another, but in the Chequer or Quincunx Order.

To execute this, the firſt Row being planted, one of the Sticks is to be removed two Foot and a half by Meaſure into the Ground, and then the other, tightening the Line. Thus there is a Row marked out of the exact Diſtance of two Foot and a half from the firſt. This done, let the Planter take a freſh Parcel of the Sets into his Apron, and taking the ſetting Stick in his Hand, let him make his firſt Hole directly oppoſite the middle Space between the firſt and ſecond Set of the former Row.

When the firſt Set is planted there, according to the Directions juſt given, let him lay down his Stick from the Top of that Set, and meaſuring thus the due Diſtance of a Foot and a half there plant another.

This he is to continue the whole Length of the Line; and there will then be a ſecond Row at two Foot and a half Diſtance from the firſt, and each Plant in it will ſtand oppoſite to the middle vacant Space between every two of the others.

When this ſecond Row is planted, the Line is again to be removed two Foot and a half farther into the Field, and a third Row is to be planted. The ſeveral Sets in this third Row are to be placed directly oppoſite to thoſe in the firſt Row; and when this is done, every four Plants of the firſt and third Row, will have one Plant of the ſecond Row in their Centre.

This Method is to be continued interchangeably through the whole Field, and this is what is called the Quincunx Manner of planting; the Effect of which is, that every Way wherein one looks at the Plantation, when the Stalks are riſen, there appear regular Rows of them the whole Extent of the Field, with regular Alleys between them.

If the Farmer aſk, Whether this we have here delivered be the exact Mannet in which Liquorice is planted in thoſe ſeveral Places we have named, we ſhall anſwer him, that it is not. They no where allow ſo great a Diſtance to the Plants; but this is an Error that has prevailed in every Article of Huſbandry, and which we hope to ſee ſet aſide one after another in them all.

Having given him in this Detail of Particulars, the Method which Experience ſhews to be beſt of all others for planting of Liquorice, we ſhall inform him what is the common Method, if he chuſe to follow it; and ſhall lay before him the Reaſons of our particular Rules on each Head.

In this let us not appear to any as being too minute and circumſtantial. The Gardiner may ſay we need not direct him how to draw his Line; but we ſhall anſwer, That it is not to him we are writing, it is the Farmer we are informing in the ſeveral Articles of his Profeſſion; and ſo much of the Gardiners Buſineſs as is needful to him, we ſhall convey in few Words, in the which he will not think us too particular.

The common Way of planting Liquorice is with leſs Regularity, and at ſmaller Diſtances. In YORKSHIRE they allow nine Inches Diſtance in the Rows, and a Foot and a half between Row and Row; and in ſome other Places, they plant the Sets at about a Foot Diſtance every Way, but without any Regard to Lines or Rows.

There may be leſs Trouble in this random Method of Planting, but there is leſs Advantage. We have ſhewn the Farmer, that whatever Price he pays for Labour, is well returned in the Encreaſe, and it is in no Inſtance more true than here.

In the random Way of planting Liquorice, all that can be done afterwards to promote its Growth, is to hoe the Ground between; but in the Method of planting in Rows, the Earth may be dug at Times between them, which is of the greateſt Advantage to the Growth; and thoſe who have a mind, may plant or ſow any ſlight rooted Crop between them. Of this we ſhall ſpeak more at large hereafter, here we are only treating of the planting the Sets.

We have ordered a large Space, but the Growth will be large accordingly; any one who can count, will be able to ſay how vaſtly greater a Number of Liquorice Roots there will be in a Field planted at nine Inches, or a Foot Diſtance; but Liquorice is not ſold by Number, but by Weight: and we will affirm, that the Quantity of Liquorice will be at the ſame Growth vaſtly greater in the diſtant than in the near Plantation.

We have ordered a ſetting Stick of a particular Form to be uſed for Liquorice, and with this Reaſon, that the Earth with ſuch a one is found to lie looſer about the Surface of the Root, which is a very great Benefit.

The common Inſtrument uſed for this Purpoſe is what they call a Dibble; this is the Handle of an old Spade, with a roundiſh Iron point. The Difference between this and the Implement we have ordered, is much more in Effect than Form. The Diſadvantage attending the Uſe of the common Dibble is this, that the Hole is made at once too large for the Set, becauſe of the Thickneſs of the Inſtrument: then as the Dibble is round, the Earth is more apt to fall in than when it is made with a ſquare Point. For this Reaſon when Liquorice is planted with the Dibble, the Planter when he has ſtuck the Inſtrument into the Ground, is obliged to work it round, in order to ſecure the Hole remaining open. This has two Diſadvantages, for the Hole being too big at firſt, is thus made much more ſo; and the Sides are caked and hardened like the Surface of a Clay Bank.

When the Set is put in, a little looſe Mould is thrown in about it, and a little more drawn over the Top; and this is all the Planter ever does, and often this but very ſlightly.

The

The Conſequence is the failing of many Plants. The Liquorice ſet in this Caſe is in a kind of Well; which, when Rains come, naturally fills with Water, and this in the cold Mornings, that are frequent in the Beginning of MARCH, chills and damps it. Often it grows mouldy, and periſhes; often it is checked in ſuch a Manner, as hardly to recover it in a long Time; and very often it grows rotten in part, though it ſurvives the Damage upon the whole; but this Damage continues with it in the whole Growth afterwards. This is the Occaſion of the Failure of many a Liquorice Plantation, when the Owner attributes it to ſome very different Cauſe.

The better the Ground has been wrought, the leſs Miſchief comes this Way; for the leſs Time the Wet can lie in the Hole, and the ſooner the Earth moulders in at the Sides and fills it up, but ſtill it is ſome Damage; and who would not avoid it when that may be done ſo very eaſily.

Our Inſtrument perfectly ſets aſide the Danger. It need not be nearly ſo thick as the Dibble, conſequently the Hole is ſmaller, and better ſuited to the Slenderneſs of the Set; and there is this double Advantage in the ſquare Shape of the Point, that the Earth remains firmer when the Hole is firſt made, without working it about for that Purpoſe; and the Angles being ſmall, it the ſooner breaks in and fills up; cloſing exactly about the Surface of the Root. To this Purpoſe it is always beſt, if the Wood Part of the Inſtrument be made ſquare as well as the Iron Point, and with ſharp Edges. This, in well wrought Ground, opens a Hole juſt fit for receiving the Set; every Part of which immediately on putting it in, breaks and cloſes about it; ſo that the whole Root is lodged in a Bed of fine, ſoft, and pliable Earth, and is in the midſt of its proper Nouriſhment.

CHAP. LXVI.

Of the Management of Liquorice when in the Ground.

WE have left our Sets planted in Rows two Foot and a half Diſtance, and at a Foot and a half in each Row; their Tops furniſhed with good Eyes, and buried with about an Inch of good Mould. The Earth is finely to be raked, and the whole Surface of the Field left quite even; nothing appearing upon it. This is its Condition in the middle of MARCH, and thus it is to be left, expecting the Advantages of ſo regular and judicious a Piece of Huſbandry.

The Heads of the young Plants will quickly appear, and they are to be left to themſelves to make their Shoot.

Toward the latter End of Spring there will be Weeds in Abundance in the Intervals, and in the Spaces between Plant and Plant in the Rows. They will be leſs abundant afterwards, becauſe the Liquorice will be better eſtabliſhed; but theſe deep-rooted Plants do not draw the Nouriſhment away from thoſe ſlight annual Weeds, like thoſe other larger Growths that ſpread out nearer the Surface.

The Weeds are at this Time to be deſtroyed, and though this might be very eaſily done with a Hand Hoe, yet there will be more Advantage in doing it by an Inſtrument which cuts deeper into the Ground.

The ſucceeding Operations of this Kind muſt be more deep than this firſt need be, but the beſt Way of doing this is by two Inſtruments; a Breaſt Plow, and a Hand Hoe of a particular Form.

The Breaſt Plow is to be of the common Shape, only ſet to cut a little deeper; and the Hoe for this Uſe ſhould be narrow, ſharp, ſtrong, and moderately hooked. Both ſhould have a good ſteeled Edge, which may be well ſharpened; for the Ground in a Liquorice Plantation is ſo fine and looſe, that there is nothing to blunt them, and they may be worked with great Eaſe.

The Breaſt Plow is to be puſhed along the Intervals between Row and Row, coming near, but not too near to the Heads of the Plants; and the Hand Hoe is to cut up the Weeds between Plant and Plant in each Row. This is beſt done firſt, and the other afterwards; becauſe otherwiſe a great deal of the Advantage of the Breaſt Plow in breaking the Ground, will be deſtroyed again by trampling over it in the Hand-hoeing.

The ſame, and indeed greater Care muſt be taken that the Tops of the Liquorice Plants are not cut off in the Handhoeing among them, than in the working of the Breaſt Plow between them; for the Danger is greater as the Strokes from the Hand are leſs regular. And this Caution is very neceſſary; for the cutting off the Top is a great Stoppage in the Growth of the Root.

When the Weeds are thus turned in, being Annuals, they will almoſt entirely rot, and ſerve as Manure. There will be no Roots of perennial Plants in the Ground, for they will have been picked out in the ſeveral Dreſſings; the Seeds of theſe Annuals are continually coming in by Accident into the Ground, and they muſt be deſtroyed as they riſe.

As it will be ſome Time before any others riſe to a Height after this firſt Dreſſing of the Ground, there muſt be Care taken of them when they do. Not that the Breaſt-plowing is to be repeated. It will be ſufficient to ſend in Labourers with the proper Hand Hoes, and to have them cut up all that appear twice during the Summer; or if it prove a very rainy one, three Times.

This may be done at a very little Charge, and the only Care needful is to avoid cutting or wounding the Liquorice Plant. This will keep the Field clear during the Summer; and in Autumn, when the Leaves are fallen, it will be very well worth while to dig up the whole Ground one full Spit deep between the Rows.

Two Months after this digging, when all is ſmooth and even, let there be ſcattered a ſmall Quantity of very rotten Dung all over the Field. This will cover the Tops of the Plants, and defend them from the Severity of the Froſts, that

are now to be expected; and the Rains that fall afterward, will, in a Manner, diſſolve the very Subſtance of the rotted Dung, carrying its Riches into the Heart of this fine looſe Earth, for the full Nouriſhment of the Plants. Thus let the Dung lie till Spring, and then taking an Opportunity of a Time when the Earth is between wet and dry, and will work eaſily. Let the Intervals between Row and Row be all thoroughly well dug again one good Spit deep as before.

This will bury the rotted Dung among the Mould, where it will ſtill work by its latent Fermentation, and break and divide as well as enrich it farther.

This done the Remainder of the Growth is only to be watched and hoed during Summer, and at Autumn the Earth is to be once dug between the Rows.

In this Manner the Liquorice is to ſtand three Years, and it will then be in the utmoſt Degree of Perfection.

It will perhaps fright the Farmer who has not been acquainted with the Profits of this Growth, to hear that his Land is to lie three Years for its Growth, and a great deal of Labour, and that of the moſt expenſive Kind, to be uſed to it during that Period: but it is only to his being unexperienced that this Concern will be owing, for the Profits of a Field of Liquorice are ſo large, that they over-pay abundantly the Time and Expences, compared with any other.

CHAP. LXVII.

Of the taking up Liquorice for Sale.

THE Time Liquorice Root takes from its planting, to grow to the utmoſt Perfection, is two Years and a half; that is, three Summers and two Winters, when we name three Years for the Time of the Grounds lying for it, 'tis including the Winter before the planting, when the Soil is preparing for the Reception of its Roots in Spring: this half Year muſt be counted by the Farmer, becauſe it is as entirely neceſſary to be beſtowed upon the Crop, as any Part of that wherein it is growing.

The Time of gathering the Roots for Sale, is late in Autumn. One reads in QUINCY's Diſpenſatory, and other popular Books, one Direction for Roots in general; where they ſay in the ſame Words, one tranſcribing from another, Roots are beſt taken up in Spring, for Reaſons obvious to all: if they had been as obvious to the Writers as they were expected to be to the Readers, I ſuppoſe thoſe Gentlemen would have named them: we ſhall ſet the Farmer right in this Reſpect, by giving him Directions juſt contrary; and as we never ſuppoſe him to know more than he is informed, we ſhall give thoſe Reaſons on which the taking them up in Autumn is founded, and this the more at large, becauſe they hold good in Reſpect of all other Roots.

Two Things are required in the Perfection of Roots, that they be full of Juice, and that the Juice be rich. On the firſt depends their good Condition, and on the other their preſerving that Condition. When they are flabby they are never full of Virtue, and when being plump and full their Juice is watery, it evaporates quickly, and the Roots loſe their good Appearance; and what is of great Conſequence to the Owner in moſt Inſtances, their Weight. Of this nothing can give a ſtronger Inſtance than Liquorice.

In order to try the Truth or Error of the popular Opinion, and to make the moſt of my Liquorice, I have taken it up at both Seaſons, and tried the Difference; what I have found is as follows.

In Autumn the Root is full, plump, and very firm to the Touch: its Colour is deeper on the Outſide, and the yellow within is clearer: its Juice is thick, and the Taſte ſweet.

In Liquorice taken up in Spring I obſerve that the Root is very plump and full, but it wants that Firmneſs which is in the other: it ſeems ſwelled, and is too tender and ſoft: its Colour is paler than it ſhould be on the Outſide, and it is of a muddy but pale yellow within. It is very full of Juice, but that is thin and watery, and the Taſte is leſs ſweet and leſs rich than in Autumn.

Theſe are Reaſons of great Weight why the Autumn ſhould be preferred for the Time of taking up this Commodity: but theſe are not all. I have found by the ſame Experience, that Liquorice taken up at Autumn will keep a conſiderable Time without waſting; loſing nothing, in a Manner, in its Weight; and retaining its full and plump Appearance; and at the ſame Time that it continues moiſt ſo long, it is little ſubject to mould or decay: on the other Hand I have ſeen, that Liquorice Roots taken up in Spring quickly change. They loſe a great deal of their Weight in a little Time, and will grow flabby, and often wrinkled on the Surface; and though the Weather be frequently more favourable at this Time, than at the Fall of the Leaf, yet they will ſooner grow mouldy.

This Experience ſhews; and I apprehend the Reaſon to be, that the Juices in the Root of Liquorice taken up in Autumn are rich, and of the Nature of the Plant, having in the greater Part been contained in its Veſſels, during a conſiderable Period of the Summer. Whereas I imagine, thoſe Juices which fill it ſo plentifully in Spring to be principally Water, juſt taken into the Root, and intended for the Support of the Stalk that is to ſhoot; a Part of them being in due Time to be converted to that rich and proper Juice, which ſwelling the Root in the End of Summer, contains in great Part the Virtues of the Plant.

Theſe ſeem natural Reaſons, and they are confirmed by Experience, for the Roots are every Way greatly preferable that are taken up at the End of Summer. In annual Plants which run to Seed, and in ſome of thoſe perennial ones which bear a very great Quantity of Seeds, the Root becomes greatly impoveriſhed after the Time of flowering; ſo that Autumn would be the worſt Time of all for taking up ſuch, but they are only a few, and Liquorice is not of the Number. The beſt Time of taking up ſuch

Roots is when the Stalk is juſt riſing, for then they are full of thoſe rich Juices which were intended to nouriſh the Stalk, Flowers, and Seeds.

Upon theſe Reaſonings, countenanced by Trial, we recommend it to the Farmer who ſhall plant Liquorice, to take it up when the Stalks and Leaves are juſt withered and fallen. Then is his Time, for then it is fulleſt of Virtue, fitteſt for Sale, and if there be Occaſion for keeping, it is in leſs Danger from thence.

The beſt Way is for him to have his Purchaſer ready before he begins to take it up, and he will at this proper End of his Labours find, that if he have followed our Directions exactly, and ſpared none of the Expence and Labour we have recommended, the Produce will not be leſs than Seventy Pounds an Acre. This is a great Profit, and the Hazard is little or nothing.

To this general and particular Account of Liquorice, we ſhall ſubjoin a Letter written by a Planter of POMFRET, in the Year 1730, to ſhew the State of the Culture and Produce at that Time.

" Planters of Liquorice divide the Roots un-
" der two ſeveral Denominations: thoſe they call
" the Stocks, are the Tops or Crown Buds;
" from whence the Liquorice Root is cut off:
" the Runners are ſmall running Roots, with
" Eyes about two Inches diſtant from each other,
" and run about two Inches below the Surface,
" three or four Foot long. Theſe Runners (be-
" fore planting) are cut into Lengths of about
" five Inches long, three Eyes to each Plant;
" though two Eyes, if they are ſtrong and good,
" will do.

" If the Ground has not been Liquorice be-
" fore, it muſt be trenched over, two Foot and
" half, or three deep; the Roots in ſoft ſandy
" Earth, will run ſix Foot deep: the Ground
" muſt be manured, or covered over with rotten
" Horſe Dung, which muſt lie a Month, or
" more, to conſume, before it is dug in. A little
" Lime is requiſite, if the Ground be ſtrong:
" but that is done after the Dung is dug in;
" and the Lime muſt be turned in about ten
" Days before planting; or elſe it will ferment,
" and heave and thruſt the Roots out of the
" Ground again.

" Before planting you are to line out your
" Ground, by a Rod of three Foot long, for
" each Bed's Breadth, and within that Space
" tread a narrow Alley, the Width of a Man's
" double Feet, or both his Shoes going one by
" another, moving ſtrait forwards by the Line,
" which makes this Direction, and which is about
" a Spade's Breadth; with which alſo you are
" to throw up the Earth out of theſe Alleys,
" upon the Tops of the Beds; the Alleys to
" be about eight Inches deep. Then draw up
" the Sides of the Beds with a ſtrong Rake; and
" (as Gardeners term it) cog the Beds with it ſo,
" as to make them round at Top: which done,
" lay the Beds in three Rows; one Row on the
" Middle of the Ridge or Bed; and the other
" two on each Side, a Foot from the Middle;
" and the Buds in the Rows at ſix Inches apart;
" firſt a Stock or Crown Bud, and then three
" Runners betwixt; then with a large Dibber,
" made of the upper Part of an old Spade,
" eight Inches in Length, as is uſed to plant
" out Garden Beans, you are to plant out your
" Buds and Runners; and beginning at one
" End of the Ridge or Bed, take the Bud in
" your left Hand, and the Dibber in your right,
" make the Depth of the Hole the full Length
" of your Dibber; then force the Bud with your
" left Hand to the Bottom of the Hole; and
" you are to cloſe it, by thruſting of the Dib-
" ber down again Sideways, pretty near the ſame
" Hole, as is done for Cabbage Plants, &c. And
" ſo working towards the left Hand, it will go
" on apace: thoſe who practiſe ſuch Works
" much, will do it very expeditiouſly.

" The Sides of the Beds muſt be drawn up
" juſt after the Buds are planted, ſo as that
" the Holes which the Dibber left may be filled
" up, in order to cover the Roots, and keep
" out the Wet.

" The firſt Year after Liquorice is planted,
" you may ſow a few Onions and Carrots upon
" the Beds, not to ſtand, but to draw whilſt
" young; and thoſe but very thin: and as far
" as you can reach with your Hand, you may
" ſow a few Radiſhes and Lettuce; and in the
" Autumn you may alſo ſow Spinage, which
" grows very fine for the Spring following, and
" which may be cut before the Liquorice grows
" much, eſpecially on the Ridge. The Profits
" which ariſe from hence may, in this one Year,
" be well computed at twelve Pounds ten Shil-
" lings an Acre; which we ſhall make appear
" by-and-by, when we come to ſtate the Debtor
" and Creditor of this Commodity.

" Liquorice at POMFRET, and other Places,
" is never in Perfection till it has ſtood three
" Years; and many there be that let it ſtand
" four, if it look heathful and lively: for Pro-
" pagation, the Runners for Sets are ſold by
" the Stone, at the ſame Price as Liquorice it-
" ſelf is at that Time; but the Stock or Crown
" Buds carry near double the Price. The Tops
" are annual, growing the firſt Year about a
" Foot high, the ſecond Year two Foot, the
" third Year four Foot; and thoſe Tops are al-
" ways cut off in Froſty Weather; which keeps
" the Roots from tearing. The Green is beſt
" to be clipped off with Garden Shears the firſt
" Year, becauſe of its being not ſo ſtrongly
" rooted as afterwards it will, when it may be
" mowed with a Scythe. The Flowers come
" out in AUGUST and SEPTEMBER; but it very
" ſeldom, or never flowers till the Plants are
" three or four Years old: they are blue, and
" hang out in ſmall Treſſes, like the Senna's,
" but above three Inches long: the Stocks are
" like thoſe of Raſberries, only ſmooth, and the
" Leaves like Seedling Aſhes.

" Liquorice is taken out of the Ground from
" MARTINMAS to the Firſt of APRIL; but the
" latter Seaſon is the beſt, both for the Liquo-
" rice and the Buds. When you take it up,
" ſort the ſmall from the great; from which
" laſt you are to dreſs the Chats with a fine
" Knife: then lay them in Sand, one Layer of
" Sand, and another Layer of Liquorice; but wet
" not the Sand with any more Moiſture, than juſt

" ſo

" ſo as that you can hold it in your Hand with-
" out running out any Water; but it ought to
" be Rock Sand, ſuch as is dug out of Pits
" about POMFRET, NOTTINGHAM, and other
" Places. You are to order the Running Buds
" or Runners in the ſame Manner, if early taken
" up: but the Crown Buds will do, if thrown
" in a Heap, and covered with Mats, &c.

" The ſmall Liquorice is, for the moſt Part,
" dried on a Malt Kiln, after it is chopped ſhort
" with a Hatchet, or ſome other edged Tool, and
" then grinded to Powder in a Mill; which is
" the readieſt Commodity of all: Or elſe it is
" pounded in a Trough whilſt it is green, and
" put into a Maſhing Tub, and maſhed with
" cold Water two Days together: then it is to
" be wrung out clean, and the Juice boiled up
" in an Iron Pot to a black Subſtance, called
" SPANISH Liquorice, and at the Place before-
" mentioned, where it is raiſed, called Liquo-
" rice Cakes. The Cakes they make at POM-
" FRET are round and flat, with a Stamp re-
" ſembling the antient Caſtle of that Town, now
" in Ruins. Within the Top of which Caſtle
" there are two Acres of Land, at this Time
" employed in the Propagation of this noble,
" uſeful Plant.

" It is further remarkable, That one Acre of
" the Ground juſt mentioned, has yielded five
" Hundred Stone Weight, which is generally
" ſold for three Shillings and Six-pence per
" Stone, in one Crop: which muſt be accounted
" good Advantage; for in three Years it a-
" mounts to eighty-ſeven Pounds ten Shillings;
" which is little leſs than thirty Pounds per
" Acre, one Year with another. Nor is the
" Charge of Tillage ſo dear, by a great deal,
" as Hops and ſeveral other Improvements are.

" Before I finiſh this Account, ſays this noted
" Correſpondent, I cannot but remark, that
" about ſeven Years ago all the Liquorice at
" POMFRET was monopolized and engroſſed by
" a Set of Merchants, &c. But the Engroſſers,
" by ſending too great a Quantity together,
" found, to their Coſt, that it heated and ſmoak-
" like a Hay-Reek put up too green. Which
" I mention by way of Precaution to thoſe that
" raiſe great Quantities, who ought not to lay
" above two hundred Stone in a Heap; for
" though this may ſeem a great Quantity, yet a
" much larger has been taken up, and tranſport-
" ed, or kept in one Parcel.

" When Liquorice is to be tranſported, all
" that is deſigned for preſent Uſe is tied up in
" ſeven or fourteen Pound Bundles, neatly rolled
" up, and bound with Pack-thread. But the
" only Way to be taken is to ſend it by Water,
" and then to lay it in dry Sand, or any other
" dry Soil, a Layer of Liquorice and a Layer
" of Sand; ſo that the Sand runs all over
" it, and amongſt it; and ſo an Apothe-
" cary may keep it good for a Twelve-month
" in his Cellar. As for tranſporting of the
" Roots for planting, if the ſmall Eye Roots,
" or Runners and Buds, were ſo tranſported in
" Sand, it were better for them, than to be
" ſent naked; eſpecially if it be a great Way,
" and they are like to lie out of the Ground
" long. If for a Journey of fourteen Days, they
" may be ſent in Bundles cut ready for plant-
" ing; but if they are to be out of the Ground
" longer, then they mould and rot. They
" ſhould not be mixed Head and Tail, if you
" ſend them any Diſtance; but muſt be bound
" up in little Bunches, as above, and tied all
" one Way, for Readineſs of planting. As for
" the Crown Buds, they may be ſent by Sea,
" with a little Sand to them, being much hardier
" than Runners are.

" At the Town of POMFRET are about fifty
" Acres of Ground, called Liquorice Garths,
" many of them in ſmall Apartments, which
" entitle the Poſſeſſors to as many Votes for
" Members of Parliament, as they are poſſeſſed
" of thoſe ſmall Parcels of Land. All which
" cauſes the Land Tillage to be very dear, the
" common Labourers having one Shilling per
" Day, and two Drinkings, which amounts in
" all to at leaſt fourteen or fifteen Pence per Day.
" But there are many other Places, where it is
" found by Experience, that there is as good
" Liquorice raiſed, as at POMFRET, and where
" Men and Buds are very eaſily procured.

" As to the Expences of planting and pre-
" ſerving of an Acre of Liquorice, the Price
" of the Roots differ in proportion to the Price
" that Liquorice bears the Year you ſend for
" them: When Liquorice gives three Shillings
" a Stone, fourteen Pounds to the Stone, then
" Crown Buds give five or ſix Shillings per
" Thouſand; and Runners, cut into Lengths,
" and tied up in Bundles, give three or four
" Shillings a Thouſand.

" Old Planters of Liquorice reckon that
" eighty Thouſand of Plants will plant an Acre:
" But computing twenty Plants to a Yard, and
" four Thouſand eight Hundred Yards to an
" Acre, then an Acre requires ninety-ſix Thou-
" ſand, at one Hundred Sixty ſquare Poles to
" an Acre, thirty Yards to a Pole ſquare, and
" twenty Roots to a Yard; as may be ſeen in
" the Example.

160 Poles in one Acre,
30 Yards in a Pole,

4800 Number of Yards in an Acre,
20 Roots to a Yard,

96000 Total of Roots to an Acre.

" Now as they generally plant one Fourth of
" Stock Buds, and three Fourths of Runners,
" then there will be required,

	l.	s.	d.
24000 Stock Buds, at 5 s. per Hund. when cheap, —— ——	6	0	0
72000 Runners, at 3 s. per Hund.	10	6	0
The Charges of preparing the Ground will be about —— ——	4	0	0
Weeding, the firſt Year, about —	4	9	0
Weeding, the ſecond Year, for it is not hoed, but weeded by the Grub and Hand, at — ——	3	0	0
The ſame Operation the third Year, at	3	0	0
The taking up and bundling the laſt Year, at —— ——	3	0	0
The Charge in all, about ——	33	15	0

" So

" So that from what goes before, and what " will by-and-by follow, it is plain that an Acre " of Liquorice will, one Year with another, as " to the Debtor and Creditor of it, ſtand as in " the under-written Scheme, the whole being " taken at an Average for three Years.

DEBTOR.

	l.	s.	d.
Three Years Rent of the Ground, at 5 l. per Acre	15	0	0
The whole Charges of planting, weeding, and gathering	33	16	0
To the Vicar for Tythe, at 2 s. per Pound, i. e. 10 s. per Acre for three Years	1	10	0
In all	50	6	0

CREDITOR.

	l.	s.	d.
Five hundred Stone of Liquorice, at 3 s. 6 d. per Stone	87	10	0
A Crop of Onions, &c. the firſt Summer	1	0	0
Some Winter's Crop for that Year	2	10	0
In all	91	0	0

Debtor and Creditor ballanced.

	l.	s.	d.
Debtor to Rent, &c.	50	6	0
Creditor in Goods ſold	91	0	0
	40	14	0

" Which is above ſixteen Pounds a Year " per Acre clear Profit, for the raiſing of Li- " quorice.

" To finiſh this Account it is plain, from " what goes before, that fifty Shillings an Acre " is allowed for the firſt Winter's Crop; but " if the Ground be ſowed with Michaelmas " Onions, Carrots, Lettuce, &c. there ſeems to " be no Reaſon why all the three Crops may " not be worth half as much, at leaſt, as the " one Summer's. And perhaps the ſame Me- " thods might be taken in other Winters, when " the Stalks are gone, as uſed to be done on " Beds, at leaſt, as it's uſed in the Alleys of Aſpa- " ragus Plantations. And by this it appears, " that if a Planter was poſſeſſed of a Hundred " Acres of Liquorice, and had a Vent for it, " it would bring him in near two Thouſand " Pounds a Year, clear of all Expences. But " an Hundred Acres is too much for one Man, " or in one County; and ſo no more of that.

" And thus, Sir, have I given you as good " an Account as I could, concerning the raiſing " of Liquorice at Pomfret, at leaſt as good " a one as the Time you gave me would allow; " though I am, I think, pretty ſure that there " is little or nothing omitted which is material, " and abſolutely neceſſary to be known in this " Affair. I wiſh you good Succeſs in all your " Undertakings,

And am, Your, &c.

" P. S. Our Liquorice Garths take up ſo many " Hands, at the Time of Year, that there " are ſcarce any Labourers to be got, at any " Rate, for other Works.

CHAP. LXVIII.

Of Saffron.

SAFFRON is a little Plant, not cultivated for its Root, as the preceding, but for a ſmall Part of its Flower. It has an extreamly ſingular Aſpect when growing, at ſome Times of the Year having the Appearance of Graſs, from its narrow Leaves; and at the Seaſon of its flowering looking much more like a Garden Flower than a Field Plant. It is very much of the Nature of thoſe Flowers called Crocus, from its Latin Name; and it is itſelf not unworthy a Place among the Ornaments of a Garden.

The Root of Saffron is roundiſh, ſingle, and large. It is one of thoſe the Gardiners call Bulbs, in all Reſpects reſembling that of the Garden Crocus. It is covered with a brown Skin, and has a Tuft of Fibres growing from the Bottom.

From the Top of this Root riſe the Leaves. They are numerous, narrow, and long, like Graſs Leaves, and of a dark green Colour.

The Flower is ſingle, it riſes at the proper Seaſon from the Midſt of the Root, and ſtands but a little Height above the Ground, but it is very large. The Colour is a blueiſh Purple, and in the Midſt of it riſe thoſe particular Filaments, or Blades, which are the Saffron.

We have given the curious Reader a particular Account of theFlowers of thoſe ſeveral Plants raiſed for Uſe in Fields, and heretofore deſcribed; informing him of the Nature and Office of their ſeveral Parts. This muſt not be eſteemed a Matter of uſeleſs Nicety. We are to give the ſame Account now of the Flower of the Saffron, and without ſo much Inſight as the Farmer has by Means of the former Deſcriptions, got into the Nature of the ſeveral Parts of Flowers, it would not be eaſy to acquaint him what the Subſtance we call Saffron, which ſells at ſo great a Price, and for the Sake of which the Plant is cultivated, truly and properly is.

We have obſerved that the Flower of the Saffron Plant is very large. It ſtands in a Kind of Huſk, rather than a Cup, which is formed of one dry Piece, unworthy to be called a Leaf, and is the Sort of Covering the Botaniſts call a Spatha or Scabbard. The Flower itſelf is formed of one Leaf, which at the Bottom has the Shape of a Tube, but in the Body of the Flower is divided into ſix large oval Parts, equal in Size, and forming a Kind of hollow Veſſel, all being of equal Height and Breadth; within this Hollow riſe three Filaments, which are ſhorter than the Flower itſelf, and have each a duſty Button at the Top, of the Shape of an Arrow Head. In the Centre of theſe, and of the Flower, grows the Rudiment of the Fruit; this is of a roundiſh Form. On the Top of it ſtands one Filament, which is of the Length of the three juſt deſcribed, but inſtead of a ſingle

Button

Button on the Top, this has there three large Blades, which are rumpled and convoluted, and notched along the Edges; theſe are properly the Saffron. Some have ſaid that the Saffron is the Filaments of the Flower, but that is an erroneous Manner of Expreſſion; the Filaments are properly thoſe three Threads which riſe from the Bottom of the Flower, and ſupport the Buttons, in which is contained the Duſt for impregnating the young Fruit; but theſe three Blades are diſtinct from them in Shape, Nature, and Office. They grow from the Top of that ſingle Thread which riſes from the Fruit, and their Buſineſs is to receive the Duſt from thoſe Buttons of the Filaments, and convey it to that Thread through which it is to reach the Body of the Fruit, and penetrating into its ſeveral Cells, to impregnate the Seeds lodged therein. The twiſted, curled, and notched Form of theſe three Blades renders them very fit for the Purpoſe of ſtopping this fine Duſt, as it is ſhed on the burſting of the Buttons of the Filaments.

When this is done the Purpoſe of Nature is anſwered by theſe Filaments, the Buttons, the three Blades, and the ſingle Thread. Theſe all therefore decay and fall off, and the Body of the Flower with them. All that remains is the Rudiment of the Fruit, which now grows larger, ripens, and becomes of a roundiſh Form. It is compoſed of three Parts, and has three Cells within, in each of which there are ſeveral Seeds of a roundiſh Figure.

Theſe are Parts the practical Huſbandman has nothing to do with, for Saffron is propagated by Roots, not by Seeds, and his Care reaches no farther than to the ripening of thoſe three Blades, which grow from the Thread of the Fruit. The Time when theſe are in their full Perfection is the Period for gathering them, and that is juſt before the Buttons of the Filaments burſt to diſcharge their Duſt.

Saffron is a Native of many Parts of EUROPE, but not of ENGLAND, though it lives very happily with us by Culture; ſo happily indeed that the ENGLISH Saffron is allowed to be the fineſt in the World: and we are ſuppoſed, from the Excellence of that Article, to be able to make the famous VENICE Treacle, in as great Perfection here, as they can in ITALY. They have the Advantage over us in the Vipers, which are one Ingredient in that Compoſition, and are more full of Virtue as well as of Poiſon in the hotter than the colder Countries, but we have as much the Advantage over them in Saffron.

The ALPS and PYRENÆAN Mountains are the Places where Saffron is moſt frequent wild; we have a Plant not unlike it wild on the Sides of ſome of our WELCH Mountains. Dr. DILLENIUS has given a Figure of it, in his Edition of RAY's Synopſis of the Engliſh Plants, but it is not the ſame with the true Saffron: its Flower, which is of the Size of that of Wood Sorrel, grows on a Stalk whereon are ſeveral ſhort Leaves, this ſhews it to be eſſentially different.

We have obſerved that all Plants thrive better on being removed from a poorer to a richer Land, this is the Caſe with Saffron; for when brought from the bleak and barren Mountains of other Parts of EUROPE, to the rich and ſheltered Plains of BRITAIN, it out grows by many Degrees its natural Condition. To this is owing the Excellence of the ENGLISH Saffron.

CHAP. LXIX.

Of the proper Soil for Saffron.

SAFFRON, although one of the moſt profitable Articles in the Way of the Huſbandman's Profeſſion, is at preſent cultivated but in few Places. Some particular Parts of ESSEX, and the Neighbourhood of a Town thence called SAFFRON WALDEN, in CAMBRIDGESHIRE, are in a Manner the only Spots of this fertile Iſland, where it is raiſed. An Attempt was made not long ſince in SURRY, but without any great Succeſs: on enquiring of Mr. JAMES OGILVIE, who was a principal Proprietor, I found that the Ignorance of thoſe who undertook the Care of it, was the great Cauſe of the Miſcarriage. Let this caution the Huſbandman who ſhall raiſe it in any new Place, yet it need not frighten him from the Deſign. Saffron is a nice Article, but with due Care it is leſs hazardous than many others; and we ſhall lay down the Principles and Rules for managing it from the Preparation of the Ground, to the delivering it from the Kiln; that none who will be attentive, and beſtow upon it the Care ſo valuable and profitable a Crop requires and demands, can fail of Succeſs.

Saffron delights in a warm flat Situation, but being accuſtomed to Expoſure it will thrive better in open Fields than Incloſures. The Fences uſed about it are to be conſidered as erected for Defence, rather than Shelter, and are to be conſtructed accordingly; of theſe we ſhall treat hereafter.

The proper Soil for Saffron is a rich light Earth, improved by Manures; it may eaſily be too wet or too rank, but it cannot be too much enriched by mellow Dung, or too much prepared by Tillage. The better it is dreſſed and broken, the richer always will be the Crop.

A very rich Loam is an exceeding good natural Soil for this Growth, or a mellow Earth in which there is ſome Quantity of Sand, for that Soil alone is too often damp, and this is a Fault of the very worſt Kind, as it will deſtroy and rot the Roots of the Saffron.

For this Reaſon alſo Care ſhould be taken to examine the Bottom, for a leſs proper Soil, with a good Bottom, will favour the Growth more than a better, with ſuch as is bad underneath.

We have ſeen that for the Culture of Liquorice there is required a great Depth of good Mould, and that a hard Gravel is the beſt Bottom: for Saffron this Depth is not at all required, for this Plant roots very ſhallow; but the Nature of the Bottom is of very great Conſequence. A hard Gravel is proper for this as well as the other; but the worſt of all others is Clay. If it happen that this lie under a deep Soil it is very prejudicial, but if it be covered only with a thin Coat of good Earth, though that Coat would be very ſufficient otherwiſe, yet with the Clay Bottom it will by no Means anſwer. The Rea-

ſon of this is, that theſe Clay Bottoms hold Water a long Time, which is of all Things moſt prejudicial to Saffron.

Next to a Gravel Bottom Chalk is accounted the moſt favourable, this is the Bed that lies under the Soil in many Places above Saffron Walden; and none ſucceed better in their Crops than thoſe who manage that Kind of Land, other Circumſtances being equal.

CHAP. LXX.

Of preparing the Ground for Saffron.

SAFFRON requires to have the Ground prepared for it at ſome Expence. Indeed we ſee throughout the Courſe of the Huſbandman's Profeſſion, that the richeſt Crops require the greateſt Preparation. The Trouble or Expence in this is nothing, to be compared with that for Liquorice, but it is very conſiderable in Compariſon with that for many other Kinds; and we have obſerved before, that the Richneſs of the Crop will be according to the Manure and Tillage uſed on the Ground.

As Expoſure is an eſſential Thing to the good Growth of Saffron, the open Fields do better for it than encloſed Countries. In thoſe Places, as it is the Cuſtom to ſow two Years, and let the Ground lie Fallow a third, and as Saffron requires Land greatly in Heart, as well as carefully tilled, the beſt Method is to take a Piece of Ground that has been fallowed. This is the firſt Thing to be conſidered, the next is to take ſuch a Piece to chuſe as has had a Crop that has not greatly exhauſted it before. There is no Growth that exhauſts Land leſs than Barley; wherefore, when the Farmer has his Choice, let him prefer ſuch Land to any other.

The Piece being fixed upon, the Saffron is to be planted in the Beginning of July, but the Preparation of the Ground muſt be begun in March.

Toward the latter End of that Month let him begin by plowing, and to ſucceed perfectly he muſt ſet out right, plowing in a particular Manner: this will be more expenſive, but that he is not to regard. The Ground muſt be plowed deep, and the Furrows drawn very cloſe to one another. This is the Way to bring all the Parts of the Soil together, and to get them all quickly into a perfect and good Tillage, and this is what he is to attempt, at the ſetting out in his Work.

When the Soil is thus properly broken, and prepared for Manure, it is to lie ſix Weeks to enjoy the Benefit of the Dews, Rains, Sun, and Air. Theſe, after ſo thoroughly plowing, will operate upon it very ſtrongly; and it will, in the Period mentioned, be greatly broke and divided, and then is the Time of laying on the Manure. We have ſaid before, that this Manure muſt be well rotted Dung, and the Reaſons are of two Kinds; for firſt, if it were freſh, it would not mix with the Soil; and, ſecondly, in that Caſe it would be too ſtrong and rank for this tender Growth. The Dung being of this Kind, ſuch as has lain a good while, and been well turned; and the Land being rendered ſhort and brittle by the Expoſure to the Air after the laſt careful Plowing, they will readily enough mix together; and it muſt be the Farmer's chief Care, that the Mixture is made in equal Proportion, one Parcel of the Ground having no more of it than another.

The proper Quantity of Dung is five and twenty Load to an Acre. The firſt Buſineſs when this is brought in, is to make the Labourers ſpread it very carefully and equally over the Ground, and it is then to be once more plowed: this is to be done in the ſame careful Manner, and it anſwers the Purpoſe of the Spade in Gardening, the Dung and Soil being prepared as before directed, they will be mixed as thoroughly by plowing as by digging by Hand.

In this Condition the Ground is to lie till the third Week in June. It then begins to be Time to think of planting the Saffron, and the laſt Preparation for it is to be made by plowing again in this Manner. The Whole is to be very carefully turned and made fine, and between every Breadth of a Pole, that is ſixteen Feet and a half, there is to be left a broad Trench. This ſerves to divide the Lands, and for a Place where to throw in the Weeds.

When this is done, the Ground is prepared and laid out for the Reception of the Crop, and nothing remains but to defend it from Cattle and other Injuries. Hedges are not required for this Purpoſe, becauſe a ſlighter Fence will ſerve, and the Saffron will thrive the better for not being too much ſheltered. The beſt Fence is a Range of Hurdles; or if the Farmer prefer it, he may run up a ſlight dead Hedge; but in that Caſe he muſt take Care to keep it tight at the Bottom, for not only Cattle are to be kept out, whoſe treading would be deſtructive, but Hares, which are very fond of eating the Saffron Leaves.

When the Farmer has thus prepared, lined out, and fenced in his Ground, it will be the Seaſon for planting his Saffron. He will find that he has juſt made all ready at the Time when he is to lay the Roots into the Ground.

CHAP. LXXI.

Of the Choice of Roots for planting.

SAFFRON is planted by the Roots, which are always to be had in the Places where it is cultivated, for it encreaſes greatly. Once in three Years every Planter of this Herb takes up his Roots, and an Acre is found to yield him from twenty to thirty Quarters of clean ones. From theſe, the others who want, are to be ſupplied, they are ſold by the Buſhel, but there is a great deal in the Choice of them. The Owner picks out the beſt for himſelf before he ſells any to his Neighbours, and it is the Buſineſs of the Purchaſer to get after this as good as he can.

The firſt Article in the Choice is, that they be perfectly ſound. Some ſell them rough, as they are picked up out of the Ground; but this is a ſlovenly and careleſs Method often injurious

to the Owner, and always hazardous to the Purchaſer.

We ſhall therefore adviſe our Planter when he comes to this Article, to have his Roots picked and cleaned for himſelf; and we ſhall here direct him to purchaſe of ſuch as have uſed the ſame Method. If he cannot, he muſt take them as they run, but they ought to come ſo much the cheaper; and he muſt pick and clean them, and examine what they are, before he commits them to the Ground: for we would have him proceed with Certainty, and there can be none where many of the Roots may fail.

There are two Reaſons why the Roots ought to come much cheaper when bought rough, not only that many may be bad, but that there will be a great deal of Dirt, waſte Matter, and old Skins that will fill up the Meaſure. However, if the Price be proportioned to the Condition, and due Care taken afterwards in examining and cleaning them; ſometimes it may prove the beſt Purchaſe, for the careleſs Owner may thus ſell his beſt Roots, and the new Planter may get ſuch as he could not have bought from any one who had his Eyes open.

The Roots of Saffron are judged of two Ways, according to their Size and Weight, and to their Shape. The ſtrongeſt Roots are always the beſt, and theſe are the largeſt and heavieſt; therefore let the Buyer, in general, avoid as much as he can the little light ſkinny Roots; and when he looks over his Purchaſe, let him throw out the lighteſt, for it is better to loſe them, than to be diſappointed by depending on them.

Let him examine them by the Eye: they are beſt which when picked from the dead Skins have the ſmootheſt and brighteſt Coat. Then let him lay them in his Hand and weigh them, the heavieſt are beſt; and after this let him preſs ſome of them gently between his Finger and Thumb, and break others. In preſſing they ſhould be found firm and ſpringy, for when flabby, and without Elaſticity, they are in a Condition of Decay; when broken, they ſhould be full of a rich freſh Juice.

Beſide theſe Marks, there is a great deal in the Shape. The large and fine Roots are all rounded or flatted, and theſe ſmall ones ſhould be in ſome Degree of the ſame Form. They never can be ſo plump, ſo round, or ſo regularly ſhaped as thoſe full grown ones, but the more they reſemble them the better.

Many of them are long and run to a point: theſe are the moſt unlike the good Roots of any, and they are to be avoided accordingly. The People in the Saffron Countries diſtinguiſh them by the Name of Spiggots, and always reject them.

The Intereſt of the Farmer is, that as many as may be of his Plants flower the firſt Year, and on this depends the Neglect of the pointed Roots, for they never do ſo. The others often will flower when very ſmall: ſo that although the Size be a great Recommendation, yet the Planter needs not reject a very ſmall Root, provided it be of a right Shape, and freſh, plump, and thriving.

CHAP. LXXII.

Of planting the Saffron.

WHEN Saffron was leſs common, and the Roots were conſequently more ſcarce, the Planters uſed to ſet them at conſiderable Diſtances; but this, though an Advantage to ſuch Herbs as ſpread their Roots a great Way, is not eſſential to ſuch a ſlight Bulb as that of this Plant.

This being now underſtood, and the Roots plentiful enough, for they increaſe at leaſt one third in three Years in every Ground; they are now planted ſo near that about four hundred Thouſand are required for an Acre.

This ſeems a prodigious Number, but as they are ſold by large Meaſures, the Quantity that Way has not ſo vaſt an Appearance, ſixteen Quarters at an Average contain about four hundred Thouſand of them, and this is the moſt profitable Quantity the Farmer can plant.

We have brought him to the Beginning of JULY. He has his Ground perfectly prepared and fenced, and his Roots before him clean picked and examined, in this Proportion of a hundred and twenty-eight Buſhels to each Acre. We are now to inform him in the moſt advantageous Manner of planting them.

A Piece of three Acres is a very advantageous Quantity, or he may make the Trial with a ſingle Acre. If he chuſe to keep more Land in this Growth afterwards, three Acre-pieces are the moſt proper, for they are found upon Experience to be the beſt and eaſieſt managed.

The Inſtrument uſed for planting theſe Roots is of a particular Kind, but eaſily underſtood, and made from a ſhort Deſcription. It is a Spade made much narrower than the common Kind, and ſlighter; with a clean Blade and a ſharp Edge: it is only to work in Ground before made perfectly fine, ſo that there will be no Occaſion for Strength to cut through heavy Clods, as in the Work done by the common Spade. This Implement they call a Spit, or a Spit Shovel, and it is the only one needful in particular for this Article.

To every Man who has his Spit Shovel for opening the Ground, there are to be two Women allowed who are to have Roots in their Aprons. The Man goes firſt, and with his Spit raiſes three or four Inches of Earth, and throws it about half a Foot before him. The two Women follow, and dexterouſly taking the Roots one by one out of their Aprons, they place them in the fartheſt Edge of the Trench, which he makes in the Manner already mentioned.

The proper Diſtance of the Roots in this Row is three Inches: there is no Occaſion for an exact Meaſure, Cuſtom will lead the Women to do it very equally, when they have been once ſhewn what is right.

When one Row is thus laid in, the Spitter prepares for another, and at the ſame Time he covers theſe. The Method is this. He works croſswiſe of the Ridge, and when he has thus gone once a-croſs it, and the Roots are in, he begins

from

from the Edge where he is, and works back again. He thus makes a new Trench as the firſt, and the Earth he throws up he turns in over the Row juſt planted. All the Care he is to take is, that he begin his Trench at ſuch a Diſtance from the Edge of the laſt where the Roots are planted, that it may be as far from the Roots to be planted in the new one to thoſe in the other, as it is from one to another of thoſe Roots in the Row: for the Meaning of his Work is, that there be an Edge of a Trench left by his ſecond Courſe a-croſs the Ridge, juſt three Inches diſtant from the firſt planted Row of Roots.

As he turns the Earth of this Trench over the Roots of the other, he will leave the Edge to be planted juſt in a Way to be covered in by the Earth of the next Trench, and ſo on. This is what he is to do at every return, croſſing the Ridge at every three Inches till the whole be finiſhed.

The Women follow him in every Trench juſt as in the firſt, and they leave the Roots planted, but naked, for him to cover; the next Trench affords the Means of covering them: and thus when the Spitter has gone through one Ridge he begins upon another, and ſo goes through the whole Land.

When he has done, all lies tolerably even, and the whole Piece of Ground is planted with Roots of Saffron regularly, at three Inches diſtant every Way.

This is no difficult Operation, but we have told the Huſbandman, that the whole Work in the raiſing of Saffron muſt be managed with exact Nicety and Care. Thus we ſhall tell him here, what the right and exact Method of the Spitter, and the Setters working is; and we recommend it ſtrongly to him to have an Eye himſelf over it, and ſee that it be done accordingly.

We have mentioned to what Depth the Spitter is to throw up the Mould in making his Trench, and we have adviſed the making the Spit with a clean Blade, and ſmooth ſharp Edge, that it may be done with Regularity. His Care muſt be to cut exactly and evenly to his Depth, and by that Means to have a level, ſound, and undiſturbed Bottom for the Roots to ſtand upon. If there be any haggling it will hurt their Growth; and as he knows on which Edge the Roots are to be placed, let him be very careful to keep the Bottom even there.

A good Workman with ſuch an Inſtrument, and in ſuch Grounds as we have deſcribed, will have a level Bottom as even as if it had been flatted by Art.

As to the Setters, there is but one Point in which they are to be careful; that is, to place the Roots directly and evenly upon their Bottom. It is in vain that an even Bed is made for them, if they are not placed evenly upon it. The great Care in the Art of Planting lies there, and if once ſo placed, the Earth that is ſo light in itſelf, and falls ſo lightly over them, will not diſturb them.

When Things are done in Haſte, they are ſeldom done with perfect Care. The Planters in the Saffron Countries are very ready and expeditious, but the Eye of the Owner ſhould be now and then upon them to ſee they do all properly. The Importance of the Crop is ſuch, that nothing can be more weak than his grudgeing this little Article of Trouble.

CHAP. LXXIII.

Of managing Saffron while in the Ground.

THOUGH a great deal of Care is needful to the profitable Management of a Crop of Saffron, it is not a continual Care. We have ſeen the Roots got into the Ground in the Beginning of July, and the Planter has no Occaſion to think of them again for two Months. His Fences are good, and his Roots well diſpoſed and deeply covered. They are then to be left to Nature; what they have to do is gradually to ſwell, to open thoſe Pores at which they are to take in Nouriſhment, to ſhoot ſome Fibres, and to receive the Juices of the Earth. This is a Work in which no Art of Man can aſſiſt them. Quiet is all they want, and the Courſe of Nature never fails, to be purſued regularly, when Man underſtands the Time, and does not intercept it.

In the Beginning of September there is Reaſon to believe all that I have deſcribed is accompliſhed: Fibres are ſhot out, the Body of the Root is replete with Juices, and the Intent of Nature is to be purſued in making the Shoot.

Something may be done at this Time to aſſiſt this important Operation, but the Period muſt be exactly watched.

The Ground being cleaned, and broke on the Surface, will wonderfully aſſiſt the puſhing of the Shoot; but if this be done too ſoon, the Earth that by its Lightneſs from the breaking, would ſo happily have aſſiſted in the forming and ſending up the Shoot will grow ſad again; and, on the contrary, if the Operation be deferred too long; that is, till the Shoot is got to ſome Length in the Ground, though it does not appear above it; the Inſtrument employed to make Way for the Shoots will cut them off, and the Damage will be very great.

The Huſbandman who is deſirous to obſerve all the needful Cautions, may aſk, How ſhall he know this exact Time? the Anſwer is eaſy. We have told him that in the Beginning of September he is to expect it; and therefore let him then examine by opening the Ground. Let him take up two or three Roots in different Places, and he will ſoon ſee whether they be in a Condition for the Operation or not.

It is needful that he make the Trial in different Parts of the Ground, becauſe from particular Accidents of Sun and Shade, or the imperfect Mixture of the Manure in ſome one Part of the Ground, if he made his Trial only in one Place, he might be deceived in judging from that of the whole Field.

The exact Condition of the Roots for this Operation, is when they have made their Shoot upwards, and it looks freſh, juicy and white,

and

and has its Point within an Inch and a half of the Surface of the Ground.

This is the true and exact Time, for it will be out of the Way of Hurt by the Inſtruments; and yet ſo near the Surface, that the Dews and Rains imbibed ſo freely, as they are by the new broken Ground, will enrich and feed it ſo, that the other Inch and a half will very quickly ſhoot, and a few Days more bring it all over the Field up above the Surface of the Ground.

The Operation to be performed at this Time is a careful Handhoeing. The Hoes for this Purpoſe ſhould be of the uſual Breadth, but a little ſtronger, well ſteeled, and ſharpened at the Edge. The Ground will be over-run with a young Growth of Weeds, but they will be all cut up and deſtroyed by this Operation.

The Hoers are to go in at one End of the Land, and Caution muſt be given them to tread lightly, and cut up carefully. Their Buſineſs is to cut about an Inch or leſs into the Ground, deſtroying all Weeds, and at the ſame Time looſening the Surface.

Theſe Hoers are to be followed by Rakers, who muſt have the ſame Caution of treading lightly; and muſt be directed to rake off all the Weeds cut up by the Hoers, into the deep Furrow or Trench we before directed to be made at the Edge of each Land for that Purpoſe. Theſe Rakers level the Surface again, ſo that when this Operation is over, the whole Field looks again like a Garden; with the Borders new dug up, quite plain and fine, and with no Plant upon it.

If there come gentle Showers after this rakeing, which is not uncommon at this Seaſon, the Owner may account himſelf particularly happy. His Field will in that Caſe remain but a very little while naked; and he will have the Pleaſure to ſee the Fruit of his Induſtry, in a riſing regular healthful Crop, that promiſe a Profit which it would be very difficult for him to obtain from the ſame Expence, and the ſame Labour, employed on any other Article whatſoever.

This we may ſay to him in general to promote his Induſtry and Attention, that the more Pains and Care he takes about any Crop, the greater will certainly be the Return in Proportion; and that if there be ſome in particular which require more than others, they are thoſe which beſt repay it.

CHAP. LXXIV.

Of the gathering of Saffron.

THE Huſbandman will underſtand the Reaſon of that ſtrict Caution we have given him, not to wound, bruiſe, or cut off the Top of the Shoot, when he ſhall be informed that this Shoot is the Rudiment of the Flower itſelf; whence all the Profit of the Crop is to be derived. An Injury to this would be irrecoverable, and it is therefore we have been ſo cautious in warning him to take Care of it, at the Time when he is hoeing the Ground, to ſupply it with freſh Nouriſhment, and to deſtroy the Weeds that would elſe drain off a Part.

This Practice of hoeing is the more eſſential, in that there is nothing at this Time to receive the Nouriſhment which it ſupplies but the Flower, and no Part of the Flower ſhews ſo plainly the Effect of a plentiful Supply, as thoſe three Blades which are the Subſtance called Saffron. They will ſhew themſelves in the Flower, however poor and mean the Plant may be; nay whatever Diſadvantages there are, theſe three Blades will always appear, not only in their due Number, but of their natural Length; but they will be thin and light in poor Ground, and they will grow fat, thick, and rich, in proportion as the Soil is naturally better, or is more improved by Art, whether the Method be by Manure or Tillage. Therefore this taking all Means to ſupply the Roots with Nouriſhment in the Beginning of SEPTEMBER, when they are riſing to flower, is of all Things the moſt eſſential in the Management of Saffron; not only the Weight, that is, the Quantity of the Produce in pure Saffron, depends upon this Richneſs and Fatneſs of theſe Blades, but its Virtue in a great Meaſure, and its good Appearance in the Cake entirely. The Price of the Saffron therefore, as well as the Quantity, depend upon this Article. We repeat and urge it the more now, that we have an Opportunity to explain it as an Introduction to the preſent Chapter on the gathering, that the Huſbandman may ſee the Neceſſity and Conſequence of doing it thoroughly and carefully.

We have told him that a few Days after this hoeing will ſhew him the young Shoots of his Crop, and that their Regularity will make a very pretty Appearance, a very little Time more will ſhew him theſe Spires all opening into Flowers, and then the Proſpect is agreeable indeed. The Saffron Plant is, as we have ſaid, one of the Flowers called Crocus's; and it is inferior to few of them in Beauty. We ſee the Field is, according to our Method, planted with all the Regularity of a Garden; there is not left the Leaf of a ſingle Weed in it, by the Hoers and the Rakers; and the Flowers now open in all their Glory. A Sight pleaſing in the greateſt Degree to the Owner, who with the Beauty ſees the Advantage.

As ſoon as the Flowers are open they are to be gathered. The Reader has been informed already, that it is only a Part of the Flower which is the Saffron, that is therefore to be picked out and ſeparated; but this is a Buſineſs that may be performed at Home; therefore 'tis not neceſſary to attempt it in the Field. The whole Flower is to be gathered there, and the reſt is to be done afterwards.

The Sun and Air have a great Effect upon the Flowers, and even upon the Leaves of Plants; we ſee them firm and plump in all their Parts in a Morning, when they are full of the Refreſhment of the Dew; at Noon, if the Sun have Power, they flag and grow lank; and toward Evening they begin to recover their Look of Health and Vigour again.

This natural Change, according to the Periods of the Day, affects nothing more than this Plant; and it affects no Part of this ſo much as the

Blades within the Flower. Theſe are plump, turged, and full of Juice in the Morning; they grow thin and poor by Noon, and they do but indifferently recruit themſelves in the Evening, the Completion of this is reſerved to the Dews of the Night; and therefore the early Morning is the only Time in which they are to be found perfectly fine. From this the Planter is to learn what is his true Time of gathering the Flowers, and how much depends upon it. He muſt ſend in a proper Number of Hands at Day-break into his Field, as ſoon as the Flowers of the Saffron appear, and theſe muſt gather till about Nine o'Clock in the Morning: they may, in Caſes of Neceſſity, ſtay an Hour longer at their Work, but this is not ſo advantageous.

It is happy for the Owner that all the Flowers of the Saffron in his Field, do not appear together. We have obſerved, in cautioning him about watching the Time of hoeing, that little Accidents may occaſion ſome Plants in the ſame Field to be earlier, and ſome later than others; and there will be the ſame Difference in their flowering. This is a great Advantage: it would be impoſſible, if they all burſt forth together, that they could be gathered properly even by any Number of Hands; but theſe little Accidents which happen in every Plantation, protract the Time of flowering for ſeveral Days; ſo that thoſe of one Morning being gathered, there is a freſh Supply open for the next, and ſo on, till the laſt have flowered.

It is farther happy alſo for the Owner, that there is no exact Degree of opening, at which theſe Flowers muſt of Neceſſity be gathered. The Saffron is beſt of all in thoſe which have the Segments juſt ſeparated at the Tops, that is, in ſuch as are juſt opening into the full Bloom, but they may be gathered before or after this Period. In general all thoſe Flowers which diſtinguiſh themſelves by their full Colour, whether they are fading or not quite opened, are each Morning to be gathered.

Here, as in all other Parts of this Product, there is to be a great deal of Care uſed, otherwiſe there will be a great deal of Loſs and Damage.

We have ſaid that a proper Number of Gatherers muſt be ready at Day-break. Each of theſe muſt have his Baſket on his Arm, and no other Preparation is neceſſary: but let there be Care taken who they are. Drunken Labourers are at all Times to be avoided, but they are to be dreaded on this. There is great Danger, that in gathering ſuch a Part of the Saffron as is fit for that Purpoſe, more may be trodden down. The Want of Light, and the Careleſſneſs of the Gatherers, are the two Things be dreaded. Happily this Work falls out at a Time when People are ſober, if they ever be ſo; but there are ſuch thorough Sots that they ſhould be examined. Though they are ready at Day-break they muſt not be ſent into the Ground till it is well light: they are then to be poſted in different Spots; and ordered to gather all the Flowers about them: firſt ſhewing them how near the Plants ſtand, and explaining to them the Miſchief of trampling them down.

As theſe People pick up the Flowers one by one, they are to throw them lightly into their Baſkets. All the Art of gathering them is, that they lay hold on the lower Part of the Flower. The Reaſon of this is, that the Flower comes off more entire when taken by this Part; and there is alſo this farther Cauſe for not touching it near the Top, that the uſeful Blades grow in the upper Part, and might be injured by the Preſſure.

Toward Nine, or half an Hour after Nine, as we have ſaid, the Gatherers ſhould deſiſt. The Care of the Farmer in this Article, is to adapt the Number to the Work. If they be too few they muſt ſtay till they have done, even if it keep them within an Hour of Noon; but as there is a Loſs to the Saffron in this, he ſhould take Care to ſend in a larger Number next Day.

The next Morning all are to be ready at the ſame Hour, and the gathering is to be performed, in all Reſpects, in the ſame Manner, and this is to be continued regularly till the whole Quantity of Saffron have flowered, and all its Produce has been regularly collected.

While they are thus employed, from Day to Day, without Doors, there is to be no Idleneſs within. The picking is there to be going forward all the while, as we ſhall ſhew in the next Chapter.

CHAP. LXXV.

Of the picking the Saffron out of the Flowers.

EVERY Morning there will be a Quantity of Flowers brought into the Houſe. The Baſkets of the Gatherers, which have been lightly filled, are to be as lightly emptied, that no Injury may be done to thoſe three Blades, which are the eſſential Part of the Flower.

The entire Flowers are to be ſcattered over a large Table, round which ſeveral Perſons can ſit in the Way to pick: four Forms are the beſt Convenience for that Purpoſe, and every Picker ſhould be allowed free Room for the Uſe of his Arms.

The very ſame People who were employed in the Morning as Gatherers, may be ſet to work, during the reſt of the Day, in picking, for they will not be wanted again for that Service till the next Morning; and he is an ill Manager, who does not contrive to have all the Saffron gathered in the Morning, picked during the Day.

The Method of picking is to take the Flower by the Bottom, between the Thumb and two Fore Fingers of the left Hand, and laying hold of the String that riſes from the Embryo of the Fruit, juſt below where the Blades of Saffron grow from it, between the Thumb and Fore Finger Nail, to nip it off there; this Part is to be laid by, and the reſt of the Flower thrown away as uſeleſs.

From time to time a Sweeper ſhould clear away about the Pickers Feet, ſweeping off the Flowers they have thrown down; and every Picker ſhould have his or her own Diſh, that the Owner may look on at Times, and ſee each does his Part in the

the Buſineſs, and that all do it right. I have ſeen great Irregularity when half a dozen People picked into one Diſh, one laying the Fault, when diſcovered, upon another; but when each works ſeparate, though all are at the ſame Table, the Senſe that he is to anſwer for what he does, without Colluſion, will keep him diligent.

The proper Part to be picked out, we have obſerved, is the three Blades of each Flower, and here we ſhall obſerve, that there may be Faults on either Side. That of Careleſſneſs in Servants is moſt frequently the Caſe, they not taking out the whole Body of theſe Blades; and on the other hand, the Avarice of the Maſter makes him ſometimes inſiſt on their taking out more, nipping off a Piece of the Filament to which they grow, along with them, by laying hold of it too low.

The firſt defrauds him of a Part of his Quantity, which in an Article of the Price of Saffron, is greatly to be regarded; the other debaſes, in ſome Degree, the Value of the Saffron, while it adds very little to the Quantity.

In order to prevent Injury from the firſt, the Owner muſt have his Eye continually upon the Work, and ſometimes look into the picked Saffron in the Diſhes, and ſometimes into the waſte Flowers thrown down upon the Floor. There is a certain Way of knowing when the Work is rightly performed, this is by obſerving the Bottoms of the Blades. Let the Farmer remember the Deſign is, that theſe be all nipped off together, by pinching off the Top of the Filament juſt below where they are inſerted. Now he will eaſily know if this be punctually done. For if the three Blades do not hold together, they have been taken off too high, and he has loſt a Part of his Saffron: on the other hand, if they have been taken off too low, he will ſee a long String to which they grow, hanging from their Baſe, by which he knows he has more than he ſhould, to the damaging, in ſome Degree, the Beauty of his Saffron. The Injury this Way is not very great, for the Colour of the Filament, though fainter than that of the Blades, is not diſtinguiſhed eaſily, when it has been preſſed and made up among them in the Cake; but the Buyers of this Commodity are now ſo good Judges, that he cannot be too careful.

It is proper to obſerve, that the Pickers have long and ſharp Nails on the Fore Finger and Thumb of the right Hand, otherwiſe they pinch it off in an aukward bungling Manner, always cruſhing the Filament to which the Blades grow, and too often the Blades themſelves. The People who expect to be employed on this Service, in the Saffron Countries, know the Uſe of preſerving theſe Nails long and in good Order; and they commonly do it at this Seaſon, but as every little Article in this Matter is of Conſequence, the Owner will do well, eſpecially when he ſhall propagate Saffron in a County where the Labouring People are not uſed to it, to beſpeak his Gatherers and Pickers in Time, and caution them to let theſe Nails grow for this Service: it will anſwer their Purpoſe as well as his, for they will go through their Work with more Eaſe and Convenience to themſelves, as well as more Regularity, by being thus provided againſt the Time, with the natural Implement for the Buſineſs.

We have adviſed the Owner to viſit his Pickers from time to time, and look carefully into their Diſhes; but he may and ought alſo to look into the Flowers they throw down as uſeleſs, for he will diſcover, by the Condition wherein they are left, as well as by the Saffron picked out of them, the Honeſty and Care of the Pickers.

If he ſee the Filament riſing from the Embryo Fruit left at its whole Length, or very nearly ſo, and its End pinched off clean and ſharp without bruiſing, he need not look into the Diſh of that Picker to ſee his Saffron; for 'tis certain from this, that the valuable Part is taken out clean, entire, and well. On the other hand, if he find Parts of the three Blades remaining on the Top of the Filament in ſome of the Flowers, and a great deal of the Filament nipped away in others, he will know by what has been ſaid already, that in the one Caſe he is defrauded of a Part of his Produce, and in the other he has a diſadvantageous Addition.

It will be proper, for the diſtinguiſhing who works well and who otherwiſe, that he make every Picker throw down his Flowers in a Heap ſeparate from the reſt, as well as collect his Saffron into a particular Diſh. By this Means he will not only ſee when Faults are committed, but always know who commits them.

This careful Inſpection will alſo keep the People at their Duty, and make thoſe honeſt through Fear of Detection, who would not be ſo in Principle. None but he who has ſeen and obſerved it, can conceive the Difference there is between Servants who work under the Eye of a careful Maſter, and thoſe who are in the Pay of a negligent Perſon, that leaves them to themſelves. To be rich the Farmer muſt be careful, and this he may ſet down as a certain Rule, that he will always have his Buſineſs done well as cheap as he can have it done amiſs; the only Difference is his own Trouble.

CHAP. LXXVI.

Of the drying of Saffron.

WHAT we have deſcribed as the Courſe and Manner of picking Saffron for one Day, is to be conſidered as applicable to every Day. We have ſeen the People ſent out to gather the Flowers that were riſen in the Morning, unloading themſelves two Hours before Noon, and employed in picking out the Saffron during the Remainder of the Day. The next Morning they are to be ſent out into the Field, to gather a freſh Parcel of Flowers, and in the ſame Manner are to be employed the reſt of the Day in picking them. Thus they are to proceed till the whole Crop of Saffron be gathered, and the whole Quantity of the Blades, or uſeful Part picked out. This is all their Buſineſs, ſo we ſhall ſpeak no more of that Part; but we muſt conſider what is to be done with this Saffron they have thus picked. We left it in their ſeveral Diſhes, ſeparated as clean, and kept as pure as the nice Eye of the Owner could obtain it,

and

and we are now to inform him in what Manner, and by what Aſſiſtances it is to be prepared for Sale.

Rich and Fat as theſe Blades of Saffron are, they would ſoon dry if left to themſelves in that Condition. This would rob them of a Part of their Virtue; and of a great deal of their Weight.

The Owner is to ſell them according to the Weight, and will have a Price proportioned to their Condition, with Reſpect to their retaining their Beauty and their Virtue. The Method of preparing them for Sale, ſo as to retain both theſe Properties, is by preſſing them together into large Cakes, by the Aſſiſtance of a ſlight Degree of Heat. This forms them into compact Maſſes, which remain in a damp or ſoft Condition, retaining the full Flavour and Colour they had while in the Flower; in this Condition they will, with due Care, keep many Years, and it is thus the Druggiſt or Dealer expects to buy them; and he will always give a Price proportioned to the Degree of Perfection with which this Work has been performed. All that regards the Management of Saffron is nice, but this is the moſt nice of all. Some Heat is abſolutely needful, but ever ſo little beyond the due Degree is hurtful; and a little Careleſſneſs in the Management of it may burn the Saffron, after which no Art can ever bring it to be worth any thing.

The drying of Saffron is effected by Means of a Kiln, but this is of a very eaſy Structure, and ſmall. We have ſaid extream Care is neceſſary in the Management of this Commodity in every Article; but it will be ſeen, in the Courſe of the whole Preparation, that very little beſide Care is neceſſary; therefore let not the Owner, who reaſonably expects ſo large a Profit, ſpare that.

Before we enter upon the Management of the Saffron at the Kiln, let us acquaint the Owner with the exact Structure of the Kiln itſelf.

In the firſt Place, it ſhould not be erected in a fixed Manner, becauſe it will be moſt convenient to move it from Place to Place; and the Degree of Fire to be uſed in it is ſo moderate, that there is no Need of hard or heavy Materials.

Firſt let the Huſbandman provide a large, broad, and thick Plank. Let him ſupport this upon four ſtrong Legs, that it may ſtand firm, but not fix theſe to the Floor, nor the Plank to the Wall: let it be as a moveable Table, that he may carry it any where, as he ſhall have Convenience or Occaſion. The Legs are to be ſhort, and ſo contrived that they may ſtand very firm and ſteady.

The Outſide of the Kiln is to be made of eight Pieces of ſound Wood, about three Inches thick, in Form of a Frame upon the Plank.

This Frame is to grow gradually wider, all the Way from the Bottom to the Top, which is to be done by ſetting the Pieces ſloping. Its beſt Breadth at the Bottom is about two Foot; and it ſhould be near two Foot at the Top. The Height of it ſhould be about equal to the Width at the Top. Two and twenty Inches high, and two and twenty Inches broad at the Top, and twelve Inches at the Bottom, is the uſual Dimenſion of the Kiln for Saffron in Cambridgeshire; and by all I have ſeen, this Size and Proportion is ſo convenient, that it would be idle to think of making any Innovation.

On the Foreſide of this Frame there is to be made a Hole eight Inches wide, and about four Inches above the Surface of the Plank. The Uſe of this is to introduce the Fire. And over all the reſt there is to be a Covering of Laths, theſe are to be of the beſt and eveneſt Kind that can be procured; and Care is to be taken to lay them regularly, evenly, and pretty cloſe together; they are to be nailed to the Frame we have juſt named, and then they are to be plaiſtered over on both Sides. The Planks are alſo to be covered very thick at the Bottom with the ſame Plaiſter, which when dry makes a Kind of Hearth and Sides for the Reception of the Fire. A Hair Cloth is to be ſtretched over the Top or wideſt Part, which is what they call the Mouth of the Kiln: this is to be fixed to the Sides of the Frame, and alſo to two Rollers, or moveable Pieces of Wood, which are turned by a Kind of Wedges, and ſerve to ſtrain and tighten the Hair Cloth on Occaſion.

When the Kiln is thus far prepared, let the Huſbandman lay in Readineſs a couple of ſmooth and tolerably thick Boards, a little larger in Length and Breadth than the Top of the Kiln; and with theſe a clean thick Blanket, and a Quire of clean white Paper.

All Things being now in Readineſs, let a Quantity of ſmall and fine Charcoal be ſet by the Kiln, to make and keep up the Fire, as Occaſion ſhall require. This muſt be clean and free from Knots, and in this Choice of it a great deal of Danger is avoided. The plaiſtered Bottom and Sides of the Kiln will very well bear the due Quantity of Fire for this Purpoſe, nor will they be injured, whatever be the Condition of the Charcoal: but this is not the Caſe with the Saffron, that requires not only a very gentle, but a very equal Heat: it is very eaſily damaged; and no Fuel will keep up ſo equal and quiet a Heat as fine even grained Charcoal, ſuch as is knotty, and of the Nature of what they call in London old Coal, is fiercer, but that Quality is not wanted on this Occaſion: there it burns irregularly, the Knots being always leſs charred, by Reaſon of their Hardneſs, than the intermediate Parts. From this it happens that the Fire, with the ſame Quantity of Fuel, is ſtronger at ſome Moments and weaker at others, which will affect the Saffron irregularly, and the knotty Parts often crack and fly, the Sparks from which will be apt to burn the Hair Cloth, and do other Damage.

Every thing being now in perfect Readineſs, let the Huſbandman proceed in this Manner. Let ſome Charcoal be lighted, and ſtand in Readineſs to put into the Kiln: then let half a dozen Sheets of Paper be evenly laid upon the Hair Cloth: upon theſe let the picked Saffron be laid three Inches thick, and ſpread very evenly and regularly, but juſt as it comes from the Pickers Hands, and without any preſſing; that is to come afterwards, when the Saffron is more in a Condition to bear it, and is to form it into thoſe thin and compact Cakes in which we ſee it.

When the Saffron is thus ſpread to a proper Thick-

Thickneſs upon the Papers, more Sheets of the ſame Paper are to be ſpread evenly over it; and then the Blanket is to be folded and doubled evenly, ſo as to bring it to a little more than the Size of the Top of the Kiln. This is to be laid upon the upper Range of Papers, and then the Fire is to be put into the Kiln. A few Pieces of the ready lighted Charcoal are firſt to be put in at the ſquare Hole in the Front, left for that Purpoſe; and upon and about theſe are to be laid more Pieces, all of them of that even and ſmooth Kind already deſcribed, and all of them ſmall, for large Pieces light unequally and burn unequally, ſo that it is never poſſible to keep the Fire at any regular Standard, which is a Thing very eſſential in this nice Work.

Chemiſts know this Article of keeping up a regular ſmall Fire, by Means of ſmall Charcoal, perfectly: none underſtand the Management of Fires like them, and therefore all others ſhould learn of them on this Occaſion. When they have very nice Operations to perform, they firſt break their picked Charcoal into Pieces of the Bigneſs of a Wallnut, or thereabout: and this is the proper Method of acting in this Article of drying the Saffron.

As to the Degree or Quantity of Fire, it muſt be proportioned to the Quantity of Saffron to be dried. 'Tis almoſt impoſſible to convey any Notion of this Matter in Words, becauſe we have not a ſufficient Variety of them; all the Terms on this Occaſion being compriſed in two, great and little: the Fire muſt be of the latter Kind, but yet it muſt be enough to affect the Saffron; the beſt Method of acquainting the unexperienced in this, is to tell him what is the Deſign of it. The Thing to be done is not the drying the Saffron at once, for that would utterly ſpoil it, what is needful is to give it ſuch a Degree of Heat at firſt, as will diſpoſe it to grow damp. This is a certain Conſequence of its being warmed and covered up, and this is what the People in the Saffron Countries call ſweating of it. Now we have informed the Huſbandman that this is the Degree of Heat required to be given it, he will not find it difficult to judge what is to be the Strength of the Fire. He will ſoon find, by the Condition of the whole, whether it be too much, too little, or juſt right; and will accordingly diminiſh, encreaſe, or continue it in the ſame State.

The firſt Hour is the moſt critical, the moſt nice, and moſt hazardous of all the Time of drying. We name this that the Owner may be properly upon his Guard.

The Fire is required to be ſtronger at firſt than at any other Time, though then but moderate, and let the Owner keep this in his Mind, for if becauſe he hears it is to be ſtronger then than afterwards, he exceeds the Bounds of Caution, he will ſcorch all the Saffron, and it will be good for nothing afterwards.

What is called the ſweating of the Saffron, is the raiſing ſome Moiſture out of the Blades, by Means of a gentle Heat, which being detained by the Covering of the Paper and the Blanket, is returned upon the Saffron again, and there works by ſoftening and mellowing the Blades; ſo that they are, after a Time, diſpoſed to unite on a gentle Preſſure, and to form together one compact Cake.

As this is the Intent, the Proceſs is to be managed accordingly. When there has been ſuch a Fire as ſerves to ſweat them properly, continued for half an Hour, the Board we have before directed to be kept in Readineſs is to be laid over the folded Blanket, and a large Weight is to be laid upon this. The mellow and ſoft Matter is now preſſed by Degrees; and preſently, from a Body of three Inches thick, as it was at firſt, is reduced to an Inch in Thickneſs.

The Fire is now to be a little leſſened, and there will be enough to continue the ſweating in a moderate Degree, for ſo much is not required now it is under Preſſure, as was while it lay looſe. The Heat and Preſſure now operate together upon the damp Saffron, and the Cake continually becomes thinner and more compact, and is kept in a Condition of Moiſture wherein it blends perfectly in all its Parts; ſo that it advances, by Degrees, toward the Condition, wherein it is to be finally made up; when this Degree of Heat has been kept up an Hour, the Huſbandman is to turn his Cake of Saffron. This he is to do in the following Manner.

The Blanket and Board, with its Weight, are all to be taken off, and the Papers, which are then the only Covering of the Saffron, are to be raiſed up, looſening the Saffron where it ſticks to them: this done the Papers are to be laid on again, covering the Cake as before, and then a thin Board is to be thruſt in between the Hair Cloth of the Kiln, and the lower Parcel of Papers: theſe are what were firſt ſpread upon the Hair Cloth, and now lie cloſe under the Saffron. When a Board is compleatly got under theſe Papers, the Cake of Saffron lies upon it, and may be eaſily turned. This is to be done carefully, and the whole, with the new ſpread upper Papers, is to be laid evenly upon the Hair Cloth of the Kiln; when that is done the Board that ſerved for turning it is to be taken away, and the Blanket, doubled as before, is to be laid over it; the Board for Preſſure is to be laid over that, and the Weight put upon it.

Every Thing is now in the ſame Condition as at firſt, except that the Cake is turned, and the ſame Degree of Heat is to be preſerved in the Kiln, that there was the laſt half Hour, which is ſomething gentler than the firſt half Hour. In this Manner the Cake is to lie one Hour: at the End of that Time the Weight, Board, and Blanket are to be taken off as before, and the Cake is to be raiſed, freed from the Papers, and examined. If there be no Miſchief done now the Danger is over, for theſe two firſt Hours have all the Hazard; for the reſt of the Time, as leſs Heat is needful, all the Care neceſſary is frequent turning.

We ſuppoſe the Cake of Saffron very well managed, and to have paſſed through the Operation of the two firſt Hours. It is then to be turned and laid on again, as before, and a gentle Heat kept up. This Heat muſt be preſerved as equally as can be for two and twenty Hours, and the Saffron muſt be turned every half Hour during that Time: when this is over, the Saffron is in the right Form, and is fit for Sale. It is to be

wrapped up in a Bladder, oiled on the Outside, and that to be again wrapped up in Leather, and the whole in Flannel. This Care keeps it in the due Condition, till required by the Purchaser, it remaining moist, tough, and in perfect fine Condition; without the Loss of Colour, Taste, Weight, or Virtue.

This is sufficient, if there be a ready Market upon the Spot, but if the Owner be obliged to keep it some time, the only proper Security is to put the whole Parcel thus wrapped up and covered, into a Leaden or Tin Box, in that Way it will keep Years.

This is the whole Management of Saffron, and we apprehend we have delivered it in so plain a Manner, that if the most unexperienced will regard every Part of the Account, we may promise him he will run no Hazard.

CHAP. LXXVII.

Of managing the latter Gatherings of Saffron.

WE have told the Husbandman he is to send out his Gatherers every Morning, so long as any Number of Flowers appear upon the Saffron Field; and we have informed him that, according to various little Accidents, there will be some Plants forwarder and some later than the Generality of the rest, by several Days; and that even what may be called the Generality of the others do not rise together, but Day after Day.

On this depends a Distinction between the better and a worse Kind of Saffron. As to those Flowers which open before the Generality of the others, they are finer than the rest, for their Forwardness is owing either to the Strength of the Roots, or the particular Richness of the Spot of the Field where they stand. The Fineness of these Flowers consists in the Largeness and Plumpness of the Chives, and these Flowers may stand to be gathered with those of the succeeding Morning, if not enough to send in for alone, because those rich Blades will support themselves in good Condition for some time after the Flower is open.

These are the richer Kind of Saffron, and they are mixed with the rest, giving a Value to the whole.

On the other Hand there are Quantities of the Plants that standing on poor Spots, or under Shelter, or from the Smallness and bad Condition of the Roots, flower much later than the Generality of the rest. As the Blades constituting the Saffron are in the more forward Plants richer than the rest, they are in these poorer, and consequently it is not to the Advantage of the Owner to mix them with the rest of his Produce; because, as the first add to the Value of the whole, these would diminish the Price, more than their Quantity would make Amends. Neither could he conveniently do it, were his Interest on the other Side.

He is to look upon these late Gatherings therefore, as a particular Kind of Saffron, inferior to the rest, and consequently to be made up separately; but still it is very well worth his Care, the very worst Saffron bringing a large Price in proportion to any other Produce.

We have explained to him what these last Gatherings are, and now shall proceed to direct him in their Management.

Let him make the Gatherers take up every Flower in these, as well as the preceding Mornings; and let him see all picked with the same Care as the others. When this is done, upon examining the Dishes, he will find the Difference between this and the former Parcels, they have been composed of large, fair, plump, and juicy Blades; but those in the Dishes now will be found small, thin, and much dryer; this is the Poorness of Saffron: it is always the Consequence of the Plant's not being well nourished. If at any Time the due Preparation of the Ground should have been neglected, every Part of the Produce would be of this poor Kind. We shall shew the Owner how that is to be managed, and the same Rule may serve him, if he is so unhappy as to have a whole Field in this Condition.

In this Case he is to prepare the Saffron in this Manner. When the Blades are picked out, and the Kiln is ready, he is to spread his Papers over the Hair Cloth, and then lay on the Saffron, as before directed, to the Thickness of four Inches instead of three, for the thicker this Parcel of the loose Blades is spread, the thicker will be the Cake: and there is nothing so advantageous to poor Saffron, as to be in a thick Mass. The thinner it is the sooner it loses its Colour and Moisture, there is none has so little, and therefore none can so ill spare it; and nothing betrays its Poorness, or reduces its Price, so much as the Dryness, or, as the Buyers call it, the Harshness of the Blades.

The Way to prevent this in the Cake is, to lay in enough at the first spreading. There is no Loss in this, for all that is put in remains; and 'tis as well to have two larger, as to have three smaller Cakes, while the larger are always, in equal Circumstances as to other Respects, the better.

When the Saffron is thus spread, the next Thing in the fine Kinds is to cover it with other Papers and the Blanket; but in this a little small Beer must be sprinkled in among it, from the End of a clean Brush, such as the Painters use.

The small Beer should be clear and stale, and a Bowl of it standing by, the Brush is to be dipped in, and when taken out and drained a little, the Handle is to be struck against a Stick, held in the Left Hand, by which Means the Beer that is left among the Hair will be scattered in very small Drops among the loose Saffron.

The Fire is now to be put in, and should be rather less than is used for the fine Saffron. The sprinkling with the Brush is to be repeated from time to time, till there be a good deal of Beer got in and perfectly mixed, and the Effect of the Heat begins to raise a little Steam from it. At this Time the upper Papers are to be laid on, and the Blanket upon them, and soon after the Board and Weight. Then the whole is to remain not an Hour, as the finer Kind, but only about five and forty Minutes, when the Board,

Blanket,

Blanket, and Papers, are to be taken off, and it is to be turned as the other Kind.

The Quantity of Beer muſt be enough to moiſten the Blades, without any running from them, and in this Management it will ſerve in the Place of that natural Moiſture they ſhould have; and they will ſweat and ſoften, and blend together, in a Manner like the fine Saffron, which they would not have done otherwiſe for want of due Moiſture. Many Things have been tried, but none anſwers this Purpoſe ſo well as Beer. I have known ſome uſe Water, but that ſubjects the Cakes to mould afterwards; others have uſed White Wine, but that draws away the Colour of the Saffron, and gives it to the Papers; others have uſed Ale, but that is too clammy; upon the whole it is a very nice Article, and of all the Things that have been tried, or perhaps ever can, there does not ſeem to be any that will anſwer ſo well as the old plain Country Practice of ſmall Beer. This is a little ſtrengthened beyond Water, and it has a little Clammyneſs, theſe are enough, it will not grow mouldy; it does not rob the Saffron of its Colour, and it gives a Toughneſs which is ſufficient without overdoing that Article.

The Cake thus managed is to be dried, in every Reſpect, in the ſame Manner as that of the finer Saffron; but it is beſt to keep the Fire throughout as it begun, a little more gentle than for the other, and to let it lie ſix or ſeven and twenty Hours in drying.

The pooreſt Saffron, thus managed, yields a thick, maſſy, and firm Cake, all the Blades of which are well mixed and blended together, which has a deep Colour, a good Conſiſtence, and ſtrong Smell. It muſt be kept in the ſame Manner as the other, but the Owner is to expect about a fifth Part Abatement in the Price. The Difference will be more if he has not managed it well; but he may always ſell it thus if he follow carefully theſe Directions, avoiding the too careleſs wetting it at firſt, and burning afterwards.

CHAP. LXXVIII.

Of certain Particularities in the preparing of Saffron.

WHAT we have ſaid of the wetting the poor Saffron, may be continued to the whole Art of managing it: ſome have attempted to alter the Kiln, and introduce new and particular Methods for the drying and curing of the Cakes, but by all that I have ſeen they are worſe than the old Way; and whatever judicious People I have known concern themſelves with them, have returned to the old Practice at laſt.

The firſt Improvement that was attempted, was to lay a Net-work of fine Iron Wire acroſs the Top of the Kiln, inſtead of the Hair Cloth. This was ſaid to have great Advantages, of which the principal was this, that the Saffron dried faſter, and with a ſmaller Quantity of Fuel.

This is true, but we have ſhewn the Huſbandman in many an Article before, that there are Savings which are the greateſt Loſſes. As to the Fuel uſed in drying Saffron, it is too trifling an Article to deſerve naming; and as to the other Article of Time, what is the beſtowing a Day and Night upon a Parcel of a Comodity the Value of which is ſo great.

The Diſadvantage that frequently attends this Method, is more than all the Good it can boaſt, by many Degrees, the Saffron is not enough defended from the abſolute Force of the Fire, in this Way, but burns if there be not the moſt exact Care taken, and often in ſpite of all the Care that can be.

The Cake it is true dries quicker, but that is a Fault; it dries too quick, for the great Benefit of the caking this Commodity, is the Time it will keep moiſt and good in that Condition, and that is the Effect of that thorough ſoaking it gets in the ſlow drying. For theſe Reaſons, tho' we have named the Iron Wire Way, for the Pleaſure of thoſe who love Variety, we adviſe the Huſbandman to go on in the uſual Manner, and prefer his Hair Cloth.

A ſecond Improvement is, the uſing Linnen Cloths inſtead of the ſeveral Parcels of Papers that are laid over and under the Saffron; there does appear to be a Poſſibility of making an Advantage of this, for the Linnen falls cloſer, and preſſes more perfectly upon the Saffron than the Paper can do; but we are not got at the compleat Management. The Cuſtom at preſent is to lay a Parcel of Papers upon the Hair Cloth, then to ſpread the Linnen over them, and upon that to lay the Saffron, which they cover with the other Linnen, and then lay on the Blanket; but there is an Inconvenience in this, for the Saffron dries too haſtily at Top, and frequently has the Marks of the Cloth on both Sides, which hurt the ſmooth and rich Appearance of it, and are not eaſily got off again.

This is not to be rejected therefore, as the Wire Covering, but improved; and the Method I ſhould propoſe to the Huſbandman's Trial is this.

Let him have a few Sheets of thin fine Paper, ſuch as in LONDON is ſold under the Name of thin Poſt, and ſome Quires of the common cheap Sort beſide. I have found that for this common Kind, what are called the Outſide Quires of printing Demy, are the fitteſt, they are large and ſmooth, and not too compact. Theſe may be bought for about Four-pence a Quire, and if there be ſome imperfect Sheets among them the Matter is not much.

I would have the Huſbandman ſet out with ſome Quires of this, a few Sheets of the thin Poſt, and a couple of Pieces of middling fine Cloth; each ſo large as, when doubled, to be of Size of the Hair Cloth. Let him alſo have his Blanket and other Matters in Readineſs, as on other Occaſions, and then let him proceed in this Manner. Having ſtretched his Hair Cloth, let him lay upon it ſome Sheets of the Demy Paper, on theſe let him lay one of his Cloths doubled; and when he has ſpread and ſtroaked this ſmooth with his Hands, let him lay evenly upon it as much of the fine Paper as will juſt cover it, cutting it into Pieces for that Purpoſe, ſo as to

make an even Bed for the Saffron, without Rumplings, or the Marks of folding.

On this let him lay his three or four Inch Thickneſs of Saffron, according as it is of a finer or an inferior Kind, and then let him cover the Saffron with another even Bed of ſingle fine Paper, and lay the ſecond double Linnen Cloth over that. Upon this let him lay on other Sheets of the Demy Paper, and then the Blanket. This done let him proceed in the Manner as already directed.

He will by this Means have the Advantage of the Linnen, which is a real Improvement without its Inconveniences, and he will preſs his Saffron into a fine Cake, without the Marks of the Texture of the Cloth.

A third Variation in the Management of Saffron at the Kiln, is the uſing a ſtuffed Pillow inſtead of the Blanket, for covering it. We name this under the Title of a Variation, becauſe it by no Means deſerves the Title of an Improvement: for it has not one Advantage over the other Method, but is in every Reſpect worſe. The Pillow, in this Caſe, is to be made of Canvaſs, and filled with Straw. We need ſay no more about a Thing which we ſo utterly condemn.

CHAP. LXXIX.

Of the Papers uſed in drying Saffron.

WE are here to mention an Article dependent upon the Saffron Trade, in which the Owner has an Advantage, but in which the Abuſes are ſo very great that, in Point of Honeſty, he ought to be upon his Guard, to diſcountenance ſuch as practiſe them.

We have obſerved that Papers are, in the common Way of drying, ſpread immediately under, and immediately over the Saffron. Now the Preſſure which connects the Blades of Saffron into a firm Cake, cannot fail to diſlodge ſome of their Juices: theſe are of a very rich Colour, and they ſtain the ſeveral Papers, penetrating through them as they lie one over another.

Theſe Papers, eſpecially ſuch as have lain next the Cake, whether above or below, are ſtrongly impregnated not only with the Colour, but the cordial Virtues of the Saffron, their Taſte manifeſts this; and they very readily communicate their Colour and Qualities to Liquors poured on them.

The Diſtillers have ſeveral Cordial Waters, Uſquebaugh of the yellow Kind, and the like, which the good old Receipts order to be coloured with Saffron, or more properly ſpeaking, they order Saffron to be put into them for its Cordial Virtues, and the fine yellow Colour comes in Conſequence.

The Diſtillers finding that there were Papers thus ſtrongly tinged with Saffron, in the common Way of curing that Commodity, bought up theſe Papers and coloured their Liquors, ſaving the Price of ſo dear an Article as Saffron.

Had the Abuſe ſtopped here the Matter had not been very great, but the next Step was, that the Apothecaries, or rather thoſe Retailers in LONDON, who call themſelves Chymiſts, and very unhappily for the Buyer, rob the Apothecary of that Part of the Profits of his Profeſſion, took theſe Papers into their Hands.

Theſe Perſons are ordered by their Diſpenſatories, to make a Syrup of Saffron, by infuſing a large Quantity of Saffron in ſtrong White Wine, and then melting the fineſt Sugar in it; but they pour a Pint of boiling Water upon a Couple of Sheets of this Paper, and ſweetening the ſtrained Liquor with two Pound of middling Sugar; they ſell this as Syrup of Saffron. They are ordered to make a Tincture of Saffron alſo, of the fineſt Saffron infuſed in Wine, or any ſtronger Liquor; but for this Purpoſe theſe People only dip ſome Saffron Papers in Wine, or Spirit, till the Liquor is yellow enough, and this is Tincture of Saffron.

In the ſame Manner they uſe theſe Papers on many other Occaſions, defrauding the Sick of that Help the Judgment of his Phyſician would have given.

To repreſent this Matter in its ſtrongeſt Light to the Cultivators of this Commodity, I ſhall tell them what is abſolutely a Fact, that the Saffron Trade is greatly hurt by this; and that it would be their Intereſt to join in a Reſolution, that no Saffron Paper ſhould ever be ſold again. This can only be done by a joint Reſolution to deſtroy all of them; and I am convinced that if they would have the Spirit, they would find the Price of Saffron riſe in one Year, ſo as to make them Amends for what they would loſe in the Sale of the Papers: the Demand muſt be greater, and the Trade would every Way feel the Benefit of it.

If this cannot be brought about, let me adviſe the Owner, for his own Sake and for the publick Good, to avoid thoſe wicked Artifices which are uſed by too many, to give more Colour to the fainter Papers. This is done with other Ingredients, not with Saffron. I ſhall not name them, leſt I give Inſtructions for a Practice againſt which I write: but certainly ſo much of this Artifice is uſed at preſent, that the Quantity of what are called Saffron Papers, uſed annually in LONDON, is ſix Times as much as all that are fairly produced in a Year. And this I mention as a farther Caution to the Saffron Owners, for it is ſtriking at the very Root of the Trade. They are very ſenſible that the Demand is not what it uſed to be, and they may be aſſured this is the Reaſon.

CHAP. LXXX.

Of the Produce of a Field of Saffron.

THE firſt Year affords the Huſbandman but a moderate Advantage in this Article, in Recompence for his Care and Expence; nay ſometimes the Crop for that Seaſon is ſcarce worth the Charge of gathering, picking, and curing; but he is to underſtand, that a Field of Saffron is planted for a three Year's Continuance, and that it is from the ſecond and third of theſe Seaſons he is to expect that great Advantage

vantage we have told him there is in raiſing this Commodity.

Nothing is more uncertain than the Quantity that ſhall be produced the firſt Year, ſometimes from a Rood of the Land there ſhall not be gathered above a Pound or two of freſh Blades, and ſometimes leſs than this; ſo that it will not pay Charges; but from this to about ſeven Pounds from the Rood, is the moſt general Produce: and at an Average, where every thing has been rightly managed, and the Seaſon moderate, the Owner may expect about five Pounds. This will yield about one Pound of Saffron prepared, and ready for Sale.

This Produce of the marketable Saffron from the wet Blades, is to be reduced to great Exactneſs. In general, if the proper Care be uſed in the ſeveral Articles already mentioned, the Owner may thus expect one Pound of ſaleable Saffron from every five of the firſt Gatherings, and about a ſixth Part leſs from the Pickings of the laſt Flowers; thoſe who uſe Ale have found, that leſs than five Pounds of the poor Blades will yield a Pound, but this is owing to a Part of the clammy Moiſture of the Ale being left in the Cake, and the Price is reduced more than the Encreaſe of Quantity compenſates: on the other hand, ſix Pounds of the ſame freſh Blades go to make a Pound of the pure Saffron, in the Way we have directed; and this is a Proof the ſmall Beer dries away, only ſerving to moiſten and ſweat the Saffron, and leaving little behind in the Cake.

The Time that a three Acre Field of Saffron will continue flowering, is in general from the firſt to the lateſt, about four Weeks. Three Weeks of this yield the fine rich Saffron, and the laſt Week only is what we call the laſt Gatherings, or yields the poorer Blades of Saffron which require that artificial Management we have named.

We have ſaid that the great Profit ariſes from the two laſt Crops of Saffron; but the Owner is not to underſtand by this, that the Produce of thoſe two Years is equal. The ſecond yields a vaſt Quantity in proportion of the firſt; and the third is the richeſt of all. The Produce of Saffron by the Acre, taking in all the Methods of Advantage we have named, may be very moderately ſet down at four and twenty Pounds of marketable Saffron for the two laſt Years, reckoned together. The firſt we have ſeen bears no Proportion to theſe at all, but this, as we ſhall ſee hereafter, is a vaſt Profit: ſo that we have not exceeded the Bounds of ſtrict Truth, when, in order to ſpirit up the Huſbandman to make the Culture of it more univerſal, we have preferred it to moſt other Crops.

CHAP. LXXXI.

Of the Management of the Saffron Field the two ſucceeding Years.

THE Owner of a new Saffron Ground, who has gathered his firſt Crop, is to know, that notwithſtanding the great Expectations to be formed of the two following, he has very little Trouble or Expence to come, the Charge and Labour of the firſt Year was his great Article in this Way.

We have conducted him to the planting, managing, and gathering his firſt Crop. The Roots retain their full Vigour afterwards, and the Ground having been ſo thoroughly prepared, will ſupply them with Nouriſhment without farther Aſſiſtance: all he is to do is to deſtroy ſuch Weeds as would draw it from his Crop, and to preſerve the Roots from Injuries as they lie in the Ground.

For the firſt Purpoſe he muſt have the Land hoed, according to the former Directions, and eſpecially regard the Seaſon for the firſt ſhooting of the Roots for flowering. This Time muſt be found by taking up a few as before, and the Operation performed in the ſame Manner: as to the latter Article, he has no Care upon his Hands but to keep his Fences good, that the Cattle, and particularly the Hares, be kept out, for they are very apt to infeſt the Saffron Fields in Winter.

As to the gathering, picking, and preparing the Saffron, it muſt be exactly the ſame in theſe ſucceeding Years that it was in the firſt, only as the Owner has been told that his Crop will be much larger, he muſt employ a greater Number of Labourers; and as he has more at Stake, he ſhould not grudge to be more careful himſelf, in the over-looking every Part of the Work.

What we have ſaid as to the preſerving the Roots quietly in the Ground, will ſeem to contradict a Cuſtom the Saffronmen have in ſome Places, of turning in their Cattle after the Leaves are fallen, to feed upon the Weeds that grow among them. But as much as our Directions contradict that Practice, juſt ſo much does that Practice run counter to Reaſon. In the firſt Place we have told the Owner, that nothing is of more Benefit to Saffron than hoeing; this is to be performed at a moderate Expence, and if repeated at proper Times there will be none of this Growth of Weeds, becauſe it will deſtroy them: and in the next Place, if this have been omitted, and there be a Growth that may ſerve the Cattle a little, their Feet will diſturb the Roots, and harden the Soil; ſo that it will much better anſwer the Purpoſe to ſend People in to mow them down occaſionally, and give them elſewhere.

According to the Principles of Tillage, on which we have founded the whole Subſtance of this Work, nothing can be more beneficial to any Crop than the breaking and dividing the Ground while it is growing. Whatever Advantage there may be in this, the ſuffering it to be trod down by Cattle has juſt a contrary Effect; for as the one looſens and divides it, the other tramples it into more Compactneſs.

Upon thoſe Principles, the longer a Crop is in the Ground, the more it will ſtand in Need of this Operation; and the richer that Crop is, the more it will deſerve it: now Saffron, as we have ſhewn, is to ſtand three Years, and is one of the richeſt Crops a Ground can bear; for theſe Reaſons hoeing ought to be frequently repeated.

The more Nouriſhment is drawn away by Weeds, the leſs is left for the Saffron; and the more compact and firm the Ground is, the leſs Benefit it receives from the Sun, Air, and Rains. Therefore let the wiſe Huſbandman frequently hoe his Saffron Fields, he will ſo give a much larger Share of Nouriſhment to the Ground, and by deſtroying the Weeds that would devour it, he will make it all go to enrich the Saffron. The Richneſs of the Saffron goes, in a very great Meaſure, to the filling the three Blades, which are its great Produce; and in Conſequence, the more he hoes the Ground the heavier they will be, that is, in the plaineſt Words, the more Saffron he will have at the Time of gathering. Nor is he to ſuppoſe this Difference in Quantity will be confined to any little Advantage. The Charge of hoeing more frequently than his Neighbours will coſt ſomething extraordinary, but of this he may be aſſured, that he will gain two Hundred per Cent. upon all the Money he ſhall expend in this Manner, in the Quantity and Excellence of his Saffron; this he will find by comparing the Produce of his Fields, with that of his Neighbours who have gone on in the uſual Way. It is certain, upon the whole, that as there are few Articles in the Province of the Huſbandman, that are ſo profitable as the Culture of Saffron, ſo there is ſcarce any in which there is Room for more Improvement. We ſee that the new Methods of Horſehoeing is not propoſed here; but the common Ways of Management are only directed in a more profitable Manner. Let the Huſbandman obſerve the ſame Conduct in every other Article, and he will not fail to enrich himſelf, to the Surprize, though not at the Expence, of his Neighbours.

CHAP. LXXXII.

Of breaking up a Saffron Ground.

THE Huſbandman has been informed that his Saffron is to ſtand three Years, and he has been conducted in every Article of its Management during that Time; we are now therefore to ſuppoſe the third Crop gathered. The Plantation has done its utmoſt, and he is to break up the Ground. The Profits he has obtained would naturally make him very unwilling to give up ſuch an Article of his Profeſſion, but he is very far from being under a Neceſſity of doing it, he muſt take up his preſent Plantation, but he is in a better Way than ever to begin another. He is now in the Condition of the Perſon from whom he bought his Roots, and as he will be able to ſupply others with ſuch as are to ſpare, he will know how to keep the beſt for himſelf.

The Nature of Saffron is like that of other bulbous Roots to encreaſe, and a Part of its Encreaſe he can now ſpare: but whatever may have been his Profits in his firſt three Years, he may promiſe himſelf much greater in the ſecond Period; becauſe he now ſets out with more Knowledge than he had firſt, and he will be at all the needful Expence and Care with more Freedom and Spirit, from his Experience. As he will therefore not fail to chuſe his Ground properly, and dreſs it well, and will ſet out with ſuch a choice Collection of Roots as he never could have got by Purchaſe, he may now look forward, and promiſe himſelf not only a much larger, but a much more certain and continual Gain.

He is now to ſet about the taking up and tranſplanting his Roots, and either uſing all to enlarge his Stock, or ſelecting what Quantity of the beſt he pleaſes, and diſpoſing of the others as he at firſt bought them, to reap a certain Advantage.

If he chuſe to enlarge his Plantations let him firſt ſeparate his Roots, the finer from the inferior, in the ſame Manner as if it were for Sale; and let him throw away the worſt. When he has made this Diviſion, let him plant his large and fine Roots in one Field, and his ſmaller and inferior for a new Growth by themſelves in another. He will find this much more advantageous than raiſing them together.

In his Deſign of enlarging the Saffron Plantation, let him conſult all Particulars: that may be often profitable in itſelf, which is not practicable by particular Perſons; and that may be profitable in one Degree, which is hurtful in another.

For theſe Reaſons let the Farmer who is about to enlarge under this Article, conſider his other Circumſtances; let him ſee whether he muſt not neglect ſomething eſſential, to fall ſo largely into this Particular; and finally, let him conſider the Number of Hands that are wanted on this Occaſion, and where he ſhall find them. We do not mean by this to diſhearten him from the Deſign of enlarging his Saffron Grounds; but would have him ſet about it with Diſcretion. We are ſenſible that the great Profit may tempt him to exceed the Bounds of Caution, in following it; and for that Reaſon lay theſe Hints before him, that if he find he cannot conſiſtently with his other neceſſary Affairs, manage a larger Crop than his former, he may content himſelf with the ſame Quantity of Ground, for that will now yield him a larger Produce and require a larger Number of Hands in proportion; or if he find he can have Opportunities, and Hands for a larger Quantity, that he may proportion his Undertakeing, not to the Golden Expectation of Profit that is before him, but to the Nature and Convenience of his other Affairs: nothing would perplex him more than to have a larger Plantation of this Kind, than he found at the Seaſon he could manage. And beſide the Vexation of Mind, nothing would be ſubject to a greater Loſs; for the gathering and curing of Saffron is a Thing that cannot be delayed when it is ready.

Hoping theſe Cautions may reſtrain within due Bounds, that Spirit of enlarging the Saffron Grounds, which ſo naturally riſes after the gathering of the laſt Crop, we ſhall proceed to the Method of taking up, managing, and replanting the Roots.

The laſt Gathering being over, and the Saffron cured for Sale, let the Field be carefully plowed up. The Farmer muſt ſee that he ſend in a careful and honeſt Fellow for this Service, as well as a good Plowman. He muſt be told, if unacquainted with this Article, the Depth at which the Roots lie, and he muſt take Care to

cut beneath them that he do not injure them, and that he turn them all up: twelve or thirteen People are to be ſent in to follow the Plow, and to pick up all the Roots they ſee turned up: each of theſe is to have his Baſket upon his Arm, to toſs the Roots into it as he gathers them from the Ground; firſt giving them a gentle Stroke againſt the Outſide of the Baſket, to ſtrike off what may happen to ſtick in Lumps about them.

When the Plow has been thus carefully thro' the Ground, and the Roots collected after it are brought in, the whole is to be harrowed twice over with a good well tined Harrow. This will penetrate four or five Inches into this light Land, which is as deep as the Roots lie; and conſequently it will bring up all, or the greateſt Part of thoſe which the Plow turned under the Mould. The ſame People are to follow in the ſame Manner as they followed the Plow, picking up every Root they ſee: and I have generally obſerved, that by that Time the Field has been twice harrowed, and the Harrow well followed each Time, there is hardly a Root left in it. Theſe Roots are to be carried to the reſt, and thrown together on a large Floor, where careful and experienced People, if ſuch there be to be had, are to be ſet to pick and clean them: if not, 'tis no great Difficulty to teach the moſt ignorant; and whether theſe or the others are employed, it will always be proper for the Owner to have an Eye upon them.

What is to be done has been in general named before, it is only to clean the Roots from Earth, from dead Parts, and from old Skins or other Foulneſs; but this is the proper Time alſo to ſeparate the fine from the others. The Cleaners ſhould be told to throw them as they work into two ſeparate Parcels; the large, plump and full into one Heap, and the ſmaller and leaner into another.

When the Roots are thus cleaned, they will keep good for ſome Time; but the moſt advantageous Method is to plant them out immediately, and that upon freſh broken Ground.

The Huſbandman who has thus far purſued the Culture of Saffron, ſhould uſe every Method to farther his Advantage, therefore what he ſhould do is this. Knowing the Time when his Roots are to be taken up, he ſhould have a freſh Piece of Land well choſen, and thoroughly prepared according to the preceding Rules, ready for the laſt working juſt at that Time. While his Roots are picking and ſeparating, he ſhould give it the laſt Plowing, and immediately after ſend in the Spitters and the Setters; giving to the laſt his choiceſt and fineſt Roots, with all the needful Cautions of placing them regularly and evenly on their Bottoms.

Thus purſuing the exact Courſe we have before laid down for him, he will in this choice Field have his fineſt Roots diſpoſed with the greateſt Regularity, in the moſt favourable Soil that is poſſible.

This Foundation laid for his great Crop, let him with the ſame Care plant his leſſer Roots in his ſecond Field; and he will be ſurprized at the Produce of the firſt, and perfectly ſatisfied with that of the latter.

We ſhould obſerve here, that as there are certain Variations in the Manner of drying the Saffron, ſo there are in the Article of breaking up the Ground. Some inſtead of plowing uſe a particular Inſtrument called a Pattock: this is a kind of forked Hoe, or prong Hoe, with ſharp and ſtrong Points; but by conſtant Obſervation upon the Effects each Way, I altogether give it for the Plowing.

This Inſtrument is very apt to wound the Roots; it is manual Labour, and therefore comes more expenſive; and it does not ſo perfectly clear the Ground.

CHAP. LXXXIII.

Of Saff-flower, or Carthamus.

WE here treat of a Plant leſs known than any other which comes under the Cognizance of the Farmer, nor is there any great Matter to be ſaid in its Recommendation: however, as it is cultivated in ſome few Parts of ENGLAND, and very much in other Parts of EUROPE; and as there may be Circumſtances that may render it advantageous to the Farmer to ſow it, we ſhall not omit to give him ſuch an Account of its Nature and Management, as may make him properly acquainted with it for his Purpoſes.

Saff Flower, or Carthamus, is cultivated for the Sake of the Flower, as the Saffron is; and probably the Culture of Saffron gave riſe to this Article, for its Flower is uſed to ſome of the ſame Purpoſes, and is called for that Reaſon baſtard Saffron.

The Plant however is utterly unlike Saffron; it is a kind of Thiſtle, and wherever it grows, whether wild or cultivated, it has very much the Appearance of a Weed.

It is an annual Plant. The Stalk is ſturdy, robuſt, and four Foot high. The Leaves are large and broad, not divided or indented, but beſet with Prickles at the Edges: the Flowers grow at the Tops of the Branches, into which the main Stalk divides towards its upper Part; and are a kind of large ſcaly Heads, ſomewhat reſembling thoſe of our Thiſtles, with a great Quantity of Threads iſſuing out at their Tops. Theſe Threads are of a moſt bright and beautiful yellow, and have been ſuppoſed by ſome to reſemble the Blades in the Flower of Saffron; but there is not much Likeneſs: it is for the Sake of theſe the Plant is cultivated principally, tho' the Seeds are alſo an Article in Trade. The Root is white and long, and it periſhes as ſoon as the Seeds are ripened. Its firſt Shoot when ſown, is in certain large broad Leaves, but theſe periſh when the Stalk riſes.

The Flower of the Carthamus examined more accurately, is found to be contained in a large common Cup: this ſerves for the ſeveral Flowers of which the whole Tuft is compoſed, and forms what we call the Head of the Carthamus: it is of an oval Form, and is compoſed of a great Number of Scales placed like Tiles one over another, and they have each the Addition of a kind of little Leaf of an oval Form. The

whole

whole Tuft is compoſed of ſeveral tubelar Flowers, each is formed of a ſingle Leaf, and has the hollow narroweſt at the Baſe, and wider all the Way to the Mouth, where it is divided into five, little, and nearly equal Segments.

In this Flower riſe five ſhort Filaments, and at the Tops of them ſtand ſo many Buttons, which are of a cylindrick Form and oblong.

In the Baſe of the Flower is depoſited the Rudiment of the Fruit: this is very ſmall and ſhort: from its Top there riſes a kind of Filament longer than the others. This is the Part to which the three Blades grow in the Flower of the right Saffron; but in this it is terminated only by a plain little Head, which ſerves to receive the Duſt from the Heads of the ſhort Filaments to impregnate the Seed.

When the whole tender Part of the Flower is faded, the ſcaly Head remains, and contains the Seeds. One follows every Flower.

Several other Species have been added to this, and called by the ſame Name, one with blue Flowers, and others with divided Leaves; but the true and proper Plant to be raiſed for Uſe, is that here deſcribed.

It is a Native of Ægypt, and ſeveral Parts of the Eaſt; and is cultivated in many of the warmer Parts of Europe: it thrives alſo very well in England.

The principal Place where we have ſeen it in England, is in ſome Parts of Norfolk; but, if worth while, it might be raiſed in any other Part of the Kingdom.

Thoſe who ſhall think it worth while to raiſe it, muſt obſerve the following Directions. In the firſt Place, let the Farmer take Care to have the Seeds from Abroad; and as often as he ſows it let him get freſh ones, for they do not ripen well in England. Theſe may be had at a very ſmall Expence, and with little Trouble. The Druggiſts ſell them, but theirs are not to be uſed, for they are commonly old. But ſuch a Quantity of it is raiſed every Year in Germany, that good Seed may always be had.

When the Seed is procured, the ſecond Care is the Ground. The beſt Soil is a dry Loam, and it does not require a rich Piece of Land of this Kind; ſo that the Charge of this Article is not great, nor indeed in any other.

The Seeds are to be ſown by Hand in a ſparing Manner, on the Land in Spring, and to be harrowed in. When they have ſhot, and the Plants have ſome Strength, they are to be thinned. Hoers ſhould be ſent into the Field for this Purpoſe, and they ſhould have Orders not only to cut up what Weeds have riſen, but to thin the Plants themſelves; leaving them at about a Foot Diſtance, and ſaving ſuch as appear the ſtrongeſt and moſt thriving. From this Time no farther Care need be taken of them: they will grow quick, and being ſtrong Plants, and thus near to one another, no Weeds will be able to get Nouriſhment among them. Early in Autumn they will begin to flower; and then the Field will make a beautiful Appearance; there is nothing can exceed the Brightneſs and golden Hue of the Flowers, nor have we any Thing of our own Growth that comes near them. The Plants branch out toward the Top, and the upper Part of every Branch is loaded with Flowers, ſo that the whole Field is covered, and as it were gilded with them.

The gathering of theſe Flowers ſo far reſembles that of Saffron, that they are to be taken as they open; for if left for ſeveral Days together, they will loſe their Colour, and that is in a Manner their whole Value.

For this Reaſon as ſoon as there is any Number of them open, the Pickers, who are in this Article the Gatherers alſo, are to be ſent into the Field. The Flowers are not gathered there and picked afterwards, but the whole Buſineſs is done at once. The whole tender Part of the Flower is to be taken, leaving the ſcaly Bud. When thoſe which are open are thus carefully picked off, they are to be ſpread upon a large Floor in an airy Place, out of the Sun to dry; and this is all that is to be done to them.

When they are dried in this Manner, they look of as beautiful a Colour as while growing, and they are ready for Sale without farther Care or Trouble.

Every Day or two the Pickers are to be then ſent into the Field as at firſt, to gather the Flowers as they ſhew themſelves, and this is to be the Method till the whole Quantity are blown; one Parcel being put to dry after another. The whole Parcel being thus prepared by a ſimple and natural drying, is ready for the Purchaſer.

If the Seaſon have been favourable, and the Crop have flowered early, ſome Seeds may ripen; but as this is ſuch a great Uncertainty, there is no Dependance upon it; and the better Method is to grub up the Plants as ſoon as the Flowers are gathered, that the Land may be prepared for ſome other Crop.

The Dyers are the People who purchaſe the Flowers; ſome have idly ſuppoſed they were of the ſame Nature with Saffron, becauſe they reſembled that Drug in ſome Degree in Appearance; but it is ſo far otherwiſe, that as Saffron is a Cordial and Sweat, theſe Flowers are a Purge, and the Seeds a Vomit.

We have mentioned the only right and honeſt Uſe of the Flowers of this Plant; but there have been ſome, when it was more cultivated than it is at preſent in Enoland, who had a Way of mixing it with Saffron when they worked it in the drying.

How improper this was we may know from the Difference of the Virtues of one and the other; but there was another Reaſon why the Farmer never ſhould have done this, which is, that it reduces the Price.

The thready Part of the Carthamus is narrow, harſh, dry, and paler coloured than the Blades of Saffron; therefore no Art can ſo blend them together, as to make them capable of impoſing upon any but the ignorant: 'twas the inferior Sort of Saffron made up from the laſt Gatherings that they mixed up in this Manner, and it reduced the Price of this ſtill lower.

One Reaſon why the foreign Saffron is held in ſo much Contempt in England is, that there is too often Carthamus among it.

CHAP. LXXXIV.

Of Madder.

MADDER is cultivated principally for the Dyers, as well as the Carthamus; though there is in this Article alſo, a Conſumption though comparatively ſmall, among the Druggiſts: but there is a great deal of Difference in the Demand; and as lightly as we have ſpoke of the other, we ſhall very ſtrongly recommend this to the Farmer, becauſe the Sale and the Profit are equally certain. 'Tis a vaſt Quantity of Madder that is annually brought into England; and we have the more Reaſon to be out of Humour with this Importation, becauſe it is brought from Places that have no Advantage over our own Fields; and frequent Experience ſhews, that the Plant will grow and thrive as freely and as well with us, as in many of thoſe Places whence we have it, at a very conſiderable Price.

The Government at one Time interfered in favour of the raiſing this uſeful Product in England, but it has been ſince almoſt utterly neglected.

Madder is a Plant of very little Beauty, and is more like a Weed than the Carthamus laſt deſcribed: it in ſome Degree reſembles the common Cleavers, or Gooſe Graſs, in its Manner of Growth, but that is larger and duſkyer coloured. 'Tis a rude irregular growing Plant. The Stalks are numerous, ſquare, and commonly of a reddiſh Colour: they are weak, ſo that they lie upon the Ground in their lower Part; and in the upper, commonly intangle one with another. The Leaves are long and narrow, they ſtand ſix at a Joint; ſometimes more, ſometimes fewer, and are diſpoſed like the Rays of a Star. Their natural Colour is a duſky green, but they ſometimes, eſpecially toward the lower Part of the Stalk, grow reddiſh. The Stalk is hairy, but theſe are more ſo: their Hairyneſs is not a woolly Down like that of ſome Plants, but is ſhort, rough, and hard, ſo that they prick the Hands when touched.

The Flowers grow at the Tops of the Stalks, and ſmall Branches; they are little, but very numerous, and of a pale yellow. The Seeds follow, which are contained in a kind of round little Heads; the Root, which is the uſeful Part, is extreamly long, and of a beautiful red Colour: duſkyer on the Surface, but very bright within.

The Cup in which the Flower of Madder ſtands is very ſmall, and ſtands upon the Rudiment of that little roundiſh Fruit in which the Seed is to be lodged: it is compoſed of a ſingle green Leaf, hollowed and divided into four little Segments at the Edge.

The Flower is in the ſame Manner formed of a ſingle Leaf, and is a little hollowed at the Bottom, and divided lightly into four Parts at the Edge. In the Centre of this riſe four ſhort Filaments, each terminated by a ſingle Button or Head: from the Rudiment of the Fruit, which, as it enlarges a little, ſhews itſelf to be compoſed of two Parts; there riſes a ſingle Filament called the Style of the Flower; this comes up in the Midſt of the four Filaments juſt named, and is divided into two Parts toward the Top, each of which has a Button to it: this through certain imperceptible Apertures, admits the Duſt from the Heads of the other Filaments for the ripening of the Seed Veſſel, which then ſwells, and becomes a kind of double Berry: in each Part of which, or each Berry, is contained a ſingle Seed.

There are two Kinds of Madder mentioned by thoſe who treat of Plants, theſe are the ſix leaved Kind we have deſcribed, and one which has only four Leaves at a Joint, but the latter is not worth the Farmer's Notice.

In Places where the right Kind is commonly cultivated, there grow up a Number of Plants in waſte Places from the ſcattered Pieces of Roots, and perhaps from the Seeds of thoſe in the manured Fields: theſe wild Plants being ſmaller and poorer than ſuch as have the Advantage of Culture, are diſtinguiſhed as a ſeparate Kind under the Name of Field, or wild Madder; but they are the ſame Plant under another Form by Accident. Therefore there is properly but one Kind of Madder, in the Conſideration of thoſe who would raiſe it for Uſe. 'Tis a Native of the Eaſt, and of ſome Parts of Europe: but its Roots in the wild State never arrive at any Thing near the Perfection of the cultivated, and that for this plain Reaſon; that in the latter Condition they run in a free, light, wrought Ground where nothing ſtops their Progreſs; and though they never attain any conſiderable Thickneſs, they run to a vaſt Length.

CHAP. LXXXV.

Of the proper Soil for Madder.

MADDER being one of thoſe Plants that roots deep, and the Value of which is in the Root; the Soil for it ſhould be deep and light. This is the principal Caution; for it will get Nouriſhment whether the Ground be richer or poorer, provided it be not altogether barren. A black Mould, ſuch as is common in the Fens of England, is very proper; and is the ſame Soil whereon they plant it in Flanders, whence we have our greater Supply. A loamy Soil that is in ſome Degree rich, and has but little Clay in its Compoſition, is alſo very proper; or a Mixture of Loam and Mould, as is very common in many Parts about the Edges of the Fen Countries.

There is no Part of England where this Plant would thrive better than in theſe Places; for they have all the Advantage of the Flemish Grounds; and this farther Benefit, that they are drier. The Flemish often burſting their Roots by their over Moiſture, or occaſioning an expenſive Manner of Dreſſing to prevent that Accident.

Whatever be the Soil for Madder it muſt be deep. We have obſerved it is the Nature of the Root to extend itſelf in Length, and that no Art can bring it to any great Thickneſs;

therefore a Depth of Soil is the moſt eſſential Point, that it may have Room to penetrate. There are uſually produced a great many Side Roots, which ſpread along juſt under the Surface of the Ground. Theſe are the Proviſion of Nature, for the Nouriſhment of the Stalk and Leaves, the great Root taking almoſt all the Juices it receives to its own Nouriſhment. Now as the Stalks and Leaves of this Plant are of no Uſe or Value, it is idle to provide for the maintaining them in Vigour at the Expence of the main Root. Theſe horizontal Shoots never come to any Value themſelves, and as they only take that Nouriſhment which ſhould ſupply the main Root, the proper Courſe is to deſtroy them.

This Account of the Nature of Madder, and of the Soil that ſuits it, naturally points out a new Method of managing it to Advantage. Of all Plants that can be raiſed, none is ſo perfectly ſuited to the Horſehoeing Huſbandry. The Soil it requires is ſuch as perfectly ſuits thoſe Implements; the Method of Horſehoeing, of all other Practice, will the moſt effectually and moſt eſſentially cut off the ſhallow and horizontal Roots; and as the main Roots are to be encouraged in their Growth to the utmoſt, no Method of planting can be ſo proper as that in Rows at a conſiderable Diſtance from one another. This directs in every Article the Horſehoeing Huſbandry, as the Method for raiſing Madder to an Excellence, and perhaps ſuch a one as it never reached any where yet in England. The Culture of this profitable and uſeful Species, has been recommended frequently and ſtrongly, and has been tried at different Times with different Succeſs, but always with ſome Profit; we hope therefore that the Farmer will be encouraged, from what has been found of the Advantages of this Crop, in Methods leſs ſuited to its Nature, to try it in the Way we are about to propoſe; in the which it cannot fail of very well anſwering his Care, Expence, and Trouble; and according to which there is a reaſonable Proſpect of his enriching himſelf by it in a few Years Culture.

CHAP. LXXXVI.

Of the Management of the Ground for Madder.

MADDER is to be planted in Spring, but the Preparation of the Ground for it muſt be undertaken long before. Let the Farmer who intends to raiſe it, look carefully out for a Field that has a deep light Soil, of the Nature of either of thoſe Kinds we have mentioned. When he has fixed upon the Field, in Autumn, as ſoon as the Crop is off the Ground, let him plow it up deeply and thoroughly with the four coultered Plow. Let him leave it in this Condition three Months, and then go over it with the ſame Plow once again: this will tear it up to a great Depth, and thoroughly break and divide it: let him then leave it to itſelf till the End of March: at this Time let him look out for ſome Sets in ſome of the Garden Grounds about London, where a Quantity of Madder is raiſed for the Supply of Covent Garden Market, and to dry for the Druggiſts, though not for Dyers. Having ſpoken about his Sets, let him, in the laſt Week in March, ſend in his four coultered Plow again, ſet to go to the greateſt Depth it can. As the Ground has been twice plowed before, it will very well give Way to this, and the third plowing being well and carefully managed, the whole Field will be turned up more than two Spit deep, and nearly as well wrought as by Hand with Spades, though at a vaſtly ſmaller Expence. The Sets are now to be taken off from the Sides and Heads of the old Roots, and the Ground is to be harrowed to lay it even. Then a Line is to be drawn along near the Edge, as in the planting of Liquorice; and the Sets are to be let into the Ground in the ſame Manner, at a Foot Diſtance from one another.

When one Row is thus planted, the Line is to be removed a Foot and half, and another Row planted, the Sets in this not being placed oppoſite to thoſe in the other, but juſt over againſt the Middle of the Space between.

The Line is then to be removed to the Diſtance of five Foot, and drawn ſtrait over the Ground as before, and a Row of the Sets are to be planted there; thus there will be a third Row at five Foot diſtance from the ſecond, and at ſix and a half from the firſt Row: the Line is then to be moved again one Foot and half, and another, being a fourth Row, is to be planted oppoſite the middle Diſtances of the laſt. Thus the whole Ground is to be planted out. The Sets are to ſtand every where at the ſame Diſtance in the Row, as at firſt ordered; and the whole Field will be laid out in double Rows, with five Foot Intervals; the Space or Partition between one Row and another, of each double Row, being one Foot and a half.

When the Sets are all in and lightly covered up, let the Planter go over the Places where they ſtand, with a Garden Rake, and lay all level.

The Beginning of April is a Seaſon when Showers are ſeldom wanting, but if it ſhould ſo happen that there are none, there muſt be the Labour of once watering the Sets. The beſt Time for doing it is on the third Day after their planting, and when this is done they may be left to Nature.

CHAP. LXXXVII.

Of managing the Crop the firſt Seaſon.

THE Plants will now quickly appear, and as this is a Time when the encreaſing Warmth of the Seaſon, and wet from the Showers, ſets every thing on growing, Weeds will appear among them. As theſe muſt be principally Seedlings, for we ſuppoſe no Roots left in the Tillage, they will not at once over-run the proper Growth, becauſe that is planted with good Roots; ſo that they need not be attacked ſo ſoon as ever they appear; but when they have got a little Height the Hand Hoers muſt be

ſent in to clear the Partitions of them between Row and Row, not meddling with thoſe in the five Foot Intervals, except juſt on the Outſide of each Row.

This is to be done with Care and Management, and a great deal depends upon it. The Inſtructions to be given the Hoers are theſe. Firſt to take Care of the Plants of Madder, which being ſet regularly, and now up at ſome Height, and being very different in their Aſpect from the Weeds, cannot well be miſtaken; all this however muſt be pointed out to them, and they muſt be ſtrictly cautioned, for the Deſtruction but of a few of the Plants where they are ſet ſeparate, and each intended for a large Growth, will be a conſiderable Loſs to the Owner. This being pointed out to them, they are to be ſent in with Directions to cut up all Weeds in the ſmall Partitions, and break the Surface of the Ground as deep as they readily can with thoſe Inſtruments; then they are to clear away between Plant and Plant of the Madder; and thence advancing to the Outſide they are to cut up the Weeds, and break the Ground for about a Hoe's Breadth all along the Rows.

This done the Plants are to be left to themſelves three Weeks, in which Time they will ſtrike very ſtrongly, and the Ground juſt about them will be very clear of Weeds, from the hoeing; but by this Time the Middle of the large Intervals will be full of Weeds of ſome Growth.

The Horſehoe is now to be ſent in, and is to cut along the Middle of each Interval, to as much Depth as it can: this will thoroughly root up and deſtroy that Growth of Weeds, and break the Ground. The Weeds will, in great Part, be buried, and will become a Kind of Manure, for Weeds that cannot grow, ſoon rot at this Seaſon, which is warm and wet; and the Ends of ſome of the longeſt Fibres of the Madder Roots will be broken off, and new ones will conſequently grow in great Quantities from them, as is ſeen in cutting of the Fibres of Roots in the Gardener's Way of planting; and there will be a fine Quantity of freſh and free Earth for theſe new Roots, as alſo for what farther Shoots the others may make; and it will be full of Nouriſhment for them.

The Syſtem of Management in this Article of Madder, varies according to the Circumſtances of Times, and it is fit we explain it to the Planter, that underſtanding the Reaſon of our Directions, he may obſerve them the more punctually.

We have told him that the main downright Roots are all that are of Value in his Madder Plants. Now the horizontal or ſpreading ones, that run under the Surface, are to be conſidered in two diſtinct Lights, as they are larger or as they are ſmaller, for at one of theſe Times they impoveriſh, but at the other they feed them; ſo that at one Time they are to be nouriſhed, and at another deſtroyed.

It is while they are young that they are of Advantage to the main Root. This is their Condition in the preſent Inſtance, and it is therefore we are recommending every Method to feed and to encreaſe them; and on the other Hand, we ſhall ſoon after take as much Pains to deſtroy them. The Part of the Madder above Ground, now though of ſome Bigneſs, is not ſo large as to demand any vaſt Quantity of Nouriſhment; the Root, on the contrary, is puſhing downward, and grows the faſter the more it is ſupplied by its Fibres, and the leſs it is drained by the Plant above.

This is the Caſe in many Inſtances at the Period of Growth whereat the Madder is at preſent, but in none more viſibly. The firſt Nouriſhment the new planted Roots take in, goes to the puſhing ſome Fibres from themſelves outward, and a Shoot of Stalk and Leaves upward. This Shoot takes up the greater Part of the Nouriſhment in the firſt Days, but afterwards it grows ſlower, and requires a ſmaller Proportion of what is drawn. After this there is a Period when the main Root is taken Care of and ſupplied, that it may be able to ſend up Nouriſhment in Abundance to the Herb, when ripening its Flowers and Seeds, that being the great Purpoſe of Nature in all Plants: for this Purpoſe alſo in Madder a Number of long horizontal Roots grow out every Way under the Surface.

Theſe horizontal Fibres we have named, and for which we are now ſo carefully providing by the Horſe Hoe, are in Time to become thoſe long horizontal or Side Roots. At preſent they are very ſerviceable, for they draw in Nouriſhment in vaſt Abundance; which being not demanded in that Quantity by the Plant in its preſent State, goes according to the Deſign of Nature, to the feeding and enlarging the main or downright Roots. The preſent Horſehoeing has vaſtly encouraged, filled, and encreaſed them; but the next is to deſtroy them.

Some Time after this Horſehoeing there will be Weeds again in the Partitions, and between Plant and Plant, for this is a Seaſon that produces them very quickly: the Hand Hoers muſt be ſent in again to cut them all up, and the Plants of the Madder being kept clear, will have a healthy Aſpect, which is very eſſential to the good Growth of the Root, and which they would not have if choaked up with Weeds: ſome Weeks after this, when the Madder has grown to a conſiderable Size, let the Horſe Hoe be ſent in a ſecond Time, with Orders to cut much nearer one Side, or one Row, alternately; by this Means all the large horizontal Roots on that Side will be cut and broken off, and only ſmall ones will grow from the Ends of them, which will tend to the Service of the main Root again.

The Hand Hoers at this laſt Time need not hoe the Outſides of all the Rows, but only alternately of thoſe near which the Horſe Hoe is not this Time to come; for the next hoeing it is to take the others. This Inſtrument could not be brought ſo near the Rows while they were young, for fear of tearing up or burying the Plants, but they are too well eſtabliſhed now to be in any Danger on that Head, eſpecially as it is done only on one Side; for the Horſe Hoe is to be carried along the fartheſt Side of the next Interval all the Way, in the Courſe of this Operation; ſo that it never comes near both Sides of the ſame Row.

The Plants will immediately after this thrive ſurpriſingly, and advance toward their flowering. There will need no more Handhoeing, for they will be now of ſuch a Size and Strength, as to deſtroy all the Weeds about them; and the next Horſehoeing, which will be the laſt for the Summer, will compleat the Work for the firſt Seaſon.

This is to be done as ſoon as the Weeds have got ſome Head again in the Intervals, for they will riſe there though they be over-powered in the Partitions. The Inſtrument is now to be carried on the other Sides of the Rows alternately, ſo that now there will have been a thorough and deep cutting up of the Ground, near both Sides of every Row.

The large horizontal Roots, which would impoveriſh the main Roots, and be of no Value in themſelves, are now broke and cut off on this Side alſo; and the main Roots, which are now large and ſtrong, have all the Advantage of the Nouriſhment.

The Flower and Seed of Madder are wholly uſeleſs: and we have ſeen, on all Occaſions, how greatly a Plant's running to Seed impoveriſhes the Root. This dictates a new Practice in the preſent Caſe, which is the cutting down the Plants juſt before they are breaking out into Flower.

Let this be done with Caution, and with Moderation. The Farmer is not to cut them down cloſe to the Ground; it is enough if he ſtop their running to Seed, therefore all he has do is to cut them off half a Foot below the Top. This will take off all the Flower Buds, and yet will leave enough of the Plant to draw up a great Quantity of Sap, and keep Nature in her proper Courſe. By this Means a vaſt Quantity of rich Juice, intended for the Perfection of the Plant in its Ripeneſs, will go to the main Root, for there will be no large Side Roots to take it up; and the Encreaſe in that uſeful Part will be very ſurpriſing.

The Stalks will ſhoot out Side Branches from the Part where they were cut off, and from every Joint below, and will grow ſtronger for that cutting, and very buſhy. Some of theſe will make an Attempt to flowering, and they may be left to themſelves in it. The few Flowers that grow upon theſe Shoots are not like the full and univerſal flowering of the whole Growth, they will do neither Good nor Harm, and are not worth regarding.

The firſt Summer will thus paſs, and the Plants not having drawn a vaſt deal of Nouriſhment upwards, the Roots will be greatly ſtrengthened and encreaſed. This will be the Condition of the Crop at the Autumn of the firſt Seaſon; and all that is to be done is in the ſame Manner to promote the Growth of the Root, during the reſt of the Time it is to remain in the Ground, which is to the next Autumn. A Crop of Madder, though it remain but eighteen Months in the Ground, is to be accounted by the Farmer as a two Years Standard, becauſe the Preparation of the Land takes up the other ſix. The whole Courſe is this, at Autumn the Ground is to be taken for it; during the Winter it is to be prepared, and in Spring it is to be planted: the next Autumn the Plants have had one Summers Growth, and they are to have another, for they muſt remain through the Winter, and the following Summer: and the Roots muſt be gathered in Autumn following, which is two Years from the Time of beginning the Preparation of the Ground.

In the uſual Way of Management, when the Roots are taken up at this Time for Sale, another Piece of Land is to be ſought out for the next Crop; but in the Method we have propoſed by the Horſehoeing Huſbandry, the ſame Piece of Ground may raiſe Madder for ever; and will be fitter for it than any other could.

CHAP. LXXXVIII.

Of managing a Crop of Madder the ſecond Seaſon.

WE have brought the Huſbandman through the firſt Summer with his Madder, and have put him into a Way of making it much finer than it can be by the common Methods in that Time; at Autumn the Stalks die away, and the Weeds die with them: and from this Time, according to the Manner of ſpeaking in the Madder Countries, they date what they call the ſecond Seaſon.

All the Winter the Ground is to lie perfectly quiet: in Spring, a Fortnight before the Plants begin to ſhoot, the Horſe Hoe ſhould be ſent in to cut a deep Furrow in the Center of every large Interval, and the Hand Hoers to cut up thoſe Weeds that riſe in the Partitions. After this there will be no more Care needful about them, for the Growth will be too ſtrong to ſuffer any Annoyance; but the Intervals will have Weeds, and ſhould be Horſehoed juſt as in the preceding Summer, to prevent their farther Growth, and to give new Supplies of Nouriſhment to the main Roots, as well as to cut away and deſtroy the Side or horizontal ones.

This is to be done exactly in the ſame Manner as before-mentioned for the firſt Seaſon, and therefore needs not be deſcribed more at large here. By this Means the Crop will proceed as it ought in every Reſpect; and this Seaſon the whole Care will be over.

In Autumn, when the Plants wither, is the Time to take up the Roots, this muſt be done with Care and Circumſpection, for the more they are broke in the Ground, the more of them is loſt. The regular Method of planting them comes in here to be of great Uſe, for the People employed to take them up know where to look for them one by one, and where they may, and where they may not, work about them.

When they are all taken up they muſt be cleaned from Dirt, and after a Quantity of fine Sets are ſeparated for a new Plantation, they are to be dried for Sale. The Dyer will be always a ready Purchaſer, nor needs the Huſbandman fear to overſtock the Market. The Uſe of the Root is to die Reds and Purples, and as an Ingredient in many other Colours: and the Quantity imported annually from Flanders, Germany, and Holland, amounts to fifteen, twenty, or twenty-five Thouſand Pounds.

CHAP. LXXXIX.

Of planting a second Crop of Madder.

IF the Husbandman be satisfied, as he very well may with the Produce of his first Crop of this Root, he may reasonably promise himself much larger Advantages from the second, because he will have, 1. More Experience and Knowledge in all the Particulars relating to its Management. 2. A better Supply of Sets; and, 3. A fourth Part more Time for their Growth, which will be no small Addition to their Bulk.

In the setting out with the Undertaking, six Months were necessary for preparing the Ground; but the Land is now all ready: the five Foot Intervals have been, during the eighteen Months Growth of the preceding Crop, in a State of Fallow; and they are now ready to receive the new Plantation, so all that Time is spared.

We shall enter regularly upon the Progress of the Business: in the Beginning of OCTOBER the Ground is clear, and the Sets are taken from the old Roots. Let this Opportunity be seized, and while these Sets are preparing for the Ground, let the Ground be also preparing for them.

The Method of planting them is to be exactly the same as at first, in double Rows, with a Foot and half Partition between the two, and with a five Foot Interval between Pair and Pair of them.

The Rows are now to be planted in the Middle of the former Intervals, and therefore the Places where they stood before, will become the Middles of so many new Intervals; and enjoying a Fallow of two Years, with frequent Tillage during the whole Time, while the new Plantation is growing, they will after that be in a Condition to feed a new Crop, and so on from Year to Year; the same Field by this Management being enabled to bear the same Produce for ever.

While the Pickers are selecting the finest and strongest Sets under the Eye of the Owner, let the four coultered Plow be again turned into the Ground. It is now to tear up the Middle of each Interval, and is to be followed by the Harrow. By that Time the Ground is thus fit, the Sets will be ready, and the sooner they are let into it the better. These will be such in Strength and Goodness, as it would be impossible for him to obtain by Purchase, and they will strike immediately on being planted.

The Lines are to be drawn in the same Manner as for the first Plantation, and the Sets let in with the same Care. They will have Time to strengthen themselves for the following Winter, and will be so rooted and fixed in the Ground by the succeeding Spring, that they will shoot in a Manner not to be expected from a Spring Plantation.

As breaking and dividing the Soil to a certain Depth, is all that is required for the well nourishing of this Crop, the Ground will be now much better than at first, because it has been continually turned and new broke during the Growth of the other; and as the Weeds which had lived upon it were always destroyed in their first Growth, and had rooted therefore but slightly, the whole Soil is full of Nourishment.

It may be questioned indeed, whether a Course of Tillage in this Way, suffers any Thing by those short Growths of Weeds or not; for as they exhaust little they return something, probably as much on being rotted in the Earth, and become a kind of natural Manure.

The Madder thus planted, is to be managed exactly as the first Crop: it is to be taken up just two Years after the Planting, and it will be found vastly preferable to the preceding. Some who have raised Madder, propose keeping it three Years in the Ground; but they certainly had not fairly and exactly tried the Difference. The Roots will gain something the third Year, but not comparable to the Disadvantage of the Loss of a whole Year's Time; neither are they always so good as they should be.

The second Autumn is the Season when this Root has arrived at its Perfection; and is the most profitable Time, on all Accounts, for taking it up.

CHAP. XC.

Of the preparing Madder Root for Sale.

THERE are different Ways of managing it when taken up; and different Forms under which it is brought to Market. But we advise the Farmer to think of nothing more than plainly drying it, and selling it entire, at least at first. It may be very well dried in a Hop Kiln, with a little Fire; and will always sell in that State.

The other Methods of managing it are by stripping off the outer Rind, then the second Bark, and so selling it in the three Forms, of the Rind, the Flesh, and the Fibre: and it may be also in either of these States ground, and sold in the Condition of Powder. For all these Purposes Labourers may easily be had from the Countries where the raising of Madder is common, and they will soon let the Owner into the manual Operation.

We are not against his undertaking all this, for we are aware of the Advantages, and would have him make the most every honest Way of his Crop: but this is not essential to the Traffick in Madder, and therefore we would not have him perplex himself by setting out with it.

Let him first raise his Madder as we have shewn, and sell it plainly dried; and after that, let him get proper People to superintend and manage the several Operations in the preparing the Root for more advantageous Sale; always having an Eye over the Work himself, and making it his chief Care to get himself as quickly as he can into the Secret of the several Practices: for if he omits this, he will lie at the Mercy of his Servants, which is a very miserable as well as hazardous Situation.

For his general Information we ſhall here add, the Terms by which Madder is called in its ſeveral States, according to theſe Ways of Preparation, and the Method at large in which they are manufactured. There is more in it than can well be conveyed in Words, for theſe manual Operations are to be learned like Trades, by Practice, not from Deſcription; but enough may be ſaid to explain the ſeveral Kinds and Forms in a ſummary Way.

When the Root is managed in that plain and eaſy Way which we have adviſed our Farmer firſt to practiſe; that is, when it is only taken out of the Ground cleaned from the Earth that hangs about it, and dried, and in that State offered to ſale, it is called Madder in the Branch.

A great deal is brought from FLANDERS in this Condition, and our People are very willing to purchaſe it: but as this is the leaſt profitable Management of it, this Branch Madder is brought principally from thoſe Places where the Trade is leaſt underſtood, or where they want Hands or Engines for the managing it according to the other Ways.

The firſt Management after this affords three Species. In order to the preparing theſe, the Root muſt firſt be dried to a certain Degree, with which thoſe who are accuſtomed to the Work are perfectly acquainted: then its ſeveral Parts ſeparating eaſily, they ſtrip off firſt the outer Skin or Rind, and next the fleſhy Part, leaving the Pith or central Matter bare and entire. Theſe they lay in three Heaps, and diſtinguiſh by three diſtinct Names.

The firſt, which is only the outer Rind, is coarſer and fouler than the reſt, this they call Mull Madder; the ſecond is firm and beautiful: from its running into Quills when it comes off entire, which have a round opening at the Ends, they call this Letter O Madder, and ſometimes Number O Madder, or plainly O Madder; the third Parcel, which is the entire Pith of the Root, and is of a paler Colour than the reſt, they call Crop Madder.

Here are four Kinds of Madder for Sale, and theſe are in Reality all the Differences in that Commodity, except the Article of reducing it to Powder; but as different Kinds according to theſe Diſtinctions may be, and are reduced to this Condition, they are called by various Names.

The ground Madder is principally, however, of two Kinds; it is either the whole Root dried, which they call Branch Madder ground to Powder; or it is the middle Part, called Number O Madder.

When the firſt Kind, or the entire Root is ground, it is uſually ſold under the Name of Bunch Madder; and when the Number O Madder is ground, its Name is Looſe Madder. Theſe are the ſeveral Terms which the Cultivator of Madder will now eaſily underſtand. It is not eſſential to him to follow theſe ſeveral Practices, but he will find it profitable. In the mean Time he may always find a ready Market for the entire Root dried, which is what the Purchaſer knows under the Name of Madder in the Branch; and without concerning himſelf farther, may thus make ſuch a Profit as will ſurprize the unacquainted with theſe Things to hear it named.

Whether all that has been ſaid of the vaſt Profits of this Species be true, we ſhall not take upon us to determine, but there is not the leaſt Doubt of its equalling any Crop that can be raiſed.

CHAP. XCI.

Of Teaſil.

THIS is an Herb raiſed for a particular Uſe in the Woollen Manufacture, which no other known Subſtance can ſo well ſupply: for this Reaſon while the Woollen Manufacture continues ſo important as it is to ENGLAND, it will be always worth the Farmers while to be acquainted with this uſeful Plant; and occaſionally, according to the Nature of his Situation, and the Demand, to cultivate it.

Teaſil is not one of thoſe univerſal Commodities for which there is every where a Market. It may be raiſed in any Place; and it is of cumberſome Carriage: therefore he muſt be very imprudent, who ſets about to cultivate it at a Diſtance from the Parts of the Kingdom where it is uſed, becauſe nothing need prevent thoſe from doing it who are upon the Spot; but to ſuch as are, it proves on many Occaſions a very profitable Growth.

The great Advantage attending it is, that it does not require the beſt of the Farmer's Ground; and that it demands very little Trouble; for after it is once up, it is too ſtrong for Weeds to grow amongſt it.

For theſe plain Reaſons, the Farmer will find that it may be often his Intereſt to raiſe it in the Cloathing Countries; and we ſhall proceed to acquaint him with the moſt profitable Manner wherein that is to be done, after we have informed him of the Aſpect and Nature of the Plant.

Teaſil is one of thoſe Plants which ſhew us moſt obviouſly the Effects of Culture. We ſee in many Inſtances Things raiſed to a Perfection in Gardens, which they never attain in their wild State, but we have ſeldom the Opportunities of comparing one with the other. In the Teaſil they are always before us. What we call wild Teaſil in the Hedges, is the very ſame with that the Farmer is to cultivate for the Uſe of the Clothier, excepting the Difference from Culture, and they may always be viewed together to ſee what that Advantage is. The Heads of the cultivated Teaſil are raiſed to a Perfection thoſe of the wild Kind never reach, and on that Change depends entirely their Uſe in the Manufacture.

The common Teaſil is well known by its tall Stalk, and great rough Heads; we ſhall therefore confine our Deſcription to that Plant as improved by Culture.

The manured Teaſil grow to the Height of ten Foot, and is a robuſt, ſtately, and very regularly growing Plant. The Root is long, thick,

thick, and white. The Stalk is very ſtiff, firm, and of a pale Colour, and is armed with Prickles. The Leaves that riſe from the Root are very large, long, and of a bright Green, and are full of ſharp pointed ſtrong Prickles. Thoſe on the Stalk are of the ſame Shape: they grow in Pairs, and joining one another at the Bottom, they ſurround it, forming a kind of Baſon round about it, which holds at all Times a great deal of Water catched from the Dews and Rains. Theſe Leaves, like the lower ones, are full of ſharp Prickles. Toward the Top of the Stalk there riſe ſeveral Branches, and theſe divide again into others toward their Extremities; and at the Top of every ſuch Diviſion there grows a large rough Head, fully as big as a Man's Fiſt, and of a ſomewhat oblong Form. This reſembles the Head of the common wild Teaſil, but is much bigger; and as it is covered in both Kinds with a Kind of ſmall tough Prickles, theſe which ſtand nearly ſtrait in the wild Kind, all bend downward in Form of Hooks, in the manured Teaſil; and by that Circumſtance it is that the Head is ſo fit for the Service of the Clothier: it becomes a Kind of Inſtrument for the dreſſing of Cloth, which for the Number, Diſpoſition, Toughneſs, and Springyneſs of its Hooks, exceeds any Thing that can be made by human Art.

Theſe Heads contain the Flowers, and Seeds of the Plant. The whole Head is a Kind of common Receptacle, holding a great Number of Flowers which appear in Succeſſion for many Days: each of theſe Flowers has its particular Cup, but that is very ſmall, and ſtands upon the Rudiment of the Fruit.

The Flower is ſmall and hollow, it is a Kind of Tube, conſiſting of a ſingle Leaf, divided into four Segments at the Edge, the upper one a little larger than the others. In the Centre of this riſe four Filaments: they are very ſlender, and are longer than the Flower, ſo that they hang out; and each of theſe has an incumbent little Head, or Button, containing the Duſt which is to impregnate the Seed. From the Top of the Rudiment of the Seed, and in the Centre of theſe Filaments riſes the Style of the Flower: at the Top of which alſo is a Button pierced for the Reception of that Duſt, and the conveying of it to the ripening Seeds: one of which follows every Flower, and is of a longiſh Shape.

There are three or four other Kinds of Teaſil mentioned by the Writers on Botany, but they are of no Importance to the Farmer: this large Kind, which is a Native of England, and many other Parts of the World; and is thus improved by Culture, is the only one he needs regard.

CHAP. XCII.

Of the proper Soil for Teaſil, and its Culture.

TO know in what Soil Teaſil will beſt ſucceed, the wiſe Method is to ſee where it grows wild. It will live in this State almoſt on any Ground, but it never is ſeen to thrive ſo well as when it chances to ſtand on a Clay, among which there are ſome Stones.

Therefore if the Farmer who reſides in the Neighbourhood of a Cloth Country, have a Piece of ſtony, clayey Ground, that is fit for little elſe, and is ſcarce worth the Charge of Manure, let him ſow it with Teaſil: he will be at no other Expence than a Couple of good Plowings, and he will have a Crop that will bring him a much larger Profit than he could make any other Way from ſuch a Piece of Land, without a great deal of Dreſſing and Expence.

There is not any Plant whoſe Culture is leſs underſtood than this, though nothing is ſo eaſy. Moſt adviſe the ſowing it in Spring, and conſequently a great deal of Trouble in weeding; and ſome allow it two Years Growth upon the Land. Theſe Methods loſe Time, and create Expence, and nothing of this is neceſſary.

The Courſe of Nature in the Production and Growth of the wild Plant is this. The Heads ripen in July, the Seeds fall out, and take root in the Ground; they ſhoot up large Leaves which ſtand through the Winter, and in Spring the Stalk riſes in the Midſt of them; which, toward the End of Summer flowers, and is in its Perfection.

'Tis ſtrange, that in the Cultivation of an Herb which is an abſolute Weed, and the Method of whoſe Growth naturally, and without Care, is ſo obvious, more have not been led to follow the Path thus beaten for them; but in departing from it as ignorantly, as wantonly, have given themſelves a great deal of Expence and Trouble.

'Tis certain, that if Teaſil be ſown in Spring, Weeds will riſe with it, and muſt be held up, becauſe they grow quick at that Time; but in Autumn they are not ſo numerous, nor of ſo quick Growth, and therefore the Plant will get the better of them. This is alſo the more the Caſe, becauſe of the natural Soil of the Teaſil, which being clayey, is one wherein few Weeds grow, and thoſe not vigorouſly. On this depends the proper Culture of the Teaſil, which we ſhall therefore direct the Farmer to obſerve in the following Manner.

If a clayey and ſtoney Soil be at hand it is beſt; if not, an abſolute Clay will do. In either Caſe let him begin the Management and Preparation of it in Autumn, as early as he can: the ſooner the better always; becauſe the quicker the Seed is got, the more Strength it will have in the Shoot before Winter.

As ſoon as the Ground is clear of any other Crop, if it have had any on it, let it be plowed deeply with the four coultered Plow: after this let it be torn to Pieces with the great Harrow; and when it has lain a few Days, plowed deeply again; this laſt plowing is to be followed by another harrowing, and then it is ready for ſowing.

While the Land is in this Preparation, let the Farmer ſeek out for Seed, and let him take eſpecial Care that it be ſound and new. The Quantity to be allowed is, a Peck to an Acre; and it is to be ſown by Hand, and harrowed in.

This

This done the Ground may be left intirely to itſelf till the Plants are up, and then there will require only one hoeing with the Hand Hoe for the whole Buſineſs.

When the Plants are up, and of ſuch a Size that the ſtrongeſt may be diſtinguiſhed from the pooreſt, let the Hoers be ſent in. They muſt have Orders to deſtroy the few Weeds there are upon the Ground, and to thin the Plants, cutting up the weakeſt and leaving the moſt promiſing, at about a Foot and a half Diſtance, this is all that needs be done. This hoeing, ſlight as it is, will diſpoſe the Ground to receive the Dews and Rains; and the remaining Warmth of the Weather and following Showers, will invigorate the Roots, ſo that the Leaves will grow larger till they meet, and ſo cover the whole Field: after this no Weeds can riſe; they will keep the Ground moiſt, and by that Means nouriſh the Roots: in Spring the Stalks will riſe, one in the Center of each Cluſter of Leaves, they will grow of themſelves in their natural Manner, and toward the End of July will be full of Heads.

This is the Time of gathering them, and it is to be done by cutting off the Stalks, and tying them up in middling Bundles. Theſe Bundles are what they call Staves of Teaſil, and they require nothing more than to be dried, in order to be fit for Uſe.

If the Weather be fair they take no more Care as to the drying, than to ſet up the Bundles in the Field, leaving it to the Sun and Wind: if there be Rain they houſe them, and dry them with a little more Trouble.

The common Produce is about a Hundred and fifty, or from that to two Hundred Staves or Bundles to an Acre; and at the pooreſt Rate they are a very profitable Crop for ſuch Land as they have grown upon, and the ſmall Expence of raiſing.

The greateſt Part of the Teaſil raiſed in England, is in Yorkshire, and in Essex; the Heads being dried, are uſed to lay the Nap of coarſe Cloths, or others, in the firſt Manufacture.

Thoſe who chuſe the Method of ſowing in Spring, muſt do it exactly in the ſame Manner as has been directed for the doing it in Autumn, but the other Way, except under very particular Circumſtances, is greatly preferable.

If any chuſe to cultivate this Plant in the Drill and Horſehoeing Way, there is no doubt but it will anſwer very well, for nothing can furniſh it ſo plentifully with Nouriſhment as Horſehoeing; and in that Way alſo the Surface of the Ground would not be at any Time ſo perfectly covered by the Leaves as it is in the other, becauſe the middle Part of the broad Intervals would certainly be free.

In this Way of raiſing Teaſil the beſt Practice would be to plant it in double Rows, with two Foot Partitions, and five Foot Intervals between Pair and Pair of Rows: the Number of Plants would be leſs upon an Acre in this Way, but probably the Number of Heads would be greater, becauſe each Plant being ſo well nouriſhed would afford a larger Number, and certainly they would be better in their Kind.

CHAP. XCIII.

Of Aniſeed.

EVERY one knows what Aniſeed is, and how great a Conſumption there is of it. We receive it from the Levant, where it is cultivated in the Greek Iſlands, and ſome other Places; but it may as well be raiſed at Home. Not only we are remiſs in this Article, but all other Nations, for the World is in a Manner ſupplied from thoſe few Places: there is no Reaſon the Backwardneſs of others, in what regards their own Intereſt, ſhould be a Rule for us to be alſo backward: not only Reaſon and the little Experience we have in Gardens, ſhew that the Plant will perfectly well live with us; but the more full and perfect Experience of the Fields where it has been ſown, and has come up, and grown to a perfect Maturity.

Let the Farmer be informed of every thing it is in his Power to raiſe upon his Land; and then let him uſe his Diſcretion, to ſuit the Crop to the Condition of his Land, and Circumſtances of his Farm.

The Plant which produces this Seed, and is called the Aniſe, and vulgarly the Aniſeſeed Plant, is not altogether unlike Parſley in its Manner of Growth. 'Tis about the ſame Height, and branches out much in the ſame Manner, and carries its Flowers and Seeds in the ſame Way in Tufts.

It grows to two Foot and a half in Height. The Root is long and white, but what is moſt ſingular in it is, that there is a great deal of Difference in the Shape of the Leaves, thoſe which riſe firſt from the Roots are compoſed of roundiſh Parts, and thoſe on the Stalk are more divided; 'tis theſe latter that have moſt the Aſpect of the Parſley Leaf, and they are of a pale Colour. The Tufts of Flowers are moderately large, but the ſeparate Flowers are ſmall, they are white, and are ſucceeded each by two Seeds which grow together.

The whole Tuft of Flowers, which is what is called an Umbell, has no ſurrounding Leaves as thoſe of many other Kinds have; and the ſeparate Flowers whereof it is compoſed, have ſcarce any viſible Cup. Each Flower conſiſts of five little Leaves, which are of an oval Figure, and bend backward: in the Center riſe five ſlender Filaments, each having at its Top a little Head or Button; among theſe grows a ſingle Filament, divided into two at the upper Part. This is the Style of the Flower, it grows upon the Rudiment of the Fruit, which is compoſed of two Seeds joined cloſe together, which ripen and ſeparate when the Flower is fallen.

CHAP. XCIV.

Of the Cultivation of Aniſeed.

ANISE is to be ſown in Spring, but the Ground muſt be well prepared for it before Hand. Therefore let the Farmer who intends

tends to raiſe it, look out for a proper Piece of Ground during the Summer, that he may be ready to go to work upon it in Autumn.

The proper Soil is a dry rich Loam; that is, ſuch a one as has a good deal of Sand, but little Clay, and a good Quantity of fine Mould in its Compoſition.

The beſt Situation is in a warm Valley, where the Place is well ſheltered by Hedges, and is not in the Way of Wet; for Aniſe is a tender Plant, and will by no Means bear Water to lodge about the Roots.

Such a Piece of Ground being choſen, let it be well plowed up in Autumn, and a Quantity of half rotted Dung ſtrewed over it. Let the plowing be repeated two or three Times between that and Spring, that the Manure may be well mixed among it; and then let it all be harrowed fine, till it be as level and ſmooth as a Border in a Garden. It is then in a Condition to be ſowed, but the Weather muſt be watched. Aniſe is a quick growing Plant, ſo that it need not be hurried into the Ground in the very Beginning of the Spring at all Adventures; the Danger to which it is liable is altogether that of the cold Rains, which ſometimes fall early in this Seaſon, and it may be eaſily guarded againſt theſe, by keeping the Seed out of the Ground till the dangerous Period is over.

The Farmer may be diſcouraged by what he meets with in ſome Writers of Credit on this Subject, who talk of the great Tenderneſs of Aniſe, and the Difficulty of raiſing it: but it is all owing to their having ſown it too early. They direct February as a proper Time, whereas it will ſucceed very well if ſown in April. Gerard, an Author of Credit, might have taught thoſe Writers better, he ſays he had frequently ſown it in his Garden, where it always grew very well; and perfectly ripened its Seeds, if the Weather proved any thing favourable.

There is therefore no Difficulty in raiſing Aniſe in England, and very little Hazard, unleſs what riſes from Ignorance: this is worth ſearching to the Bottom, becauſe it may prove a very valuable Commodity: the Price is not great as we import it, but when we conſider the vaſt Quantity of Seed which all theſe umbelliferous Plants bear, we ſhall find that it will amount to a very conſiderable Value from an Acre.

The Ground being ready, the next Thing the Farmer is to do is to ſee that he get good Seed, the Soundneſs is one great Article, and the Freſhneſs is another. If he buy ſuch as is faulty and decayed, he will have a poor Crop, becauſe one half of it will never ſprout; and if it be old Seed, though good and ſound, yet it will from that alone be made very inconvenient to him, on Account of the late ſhooting. As we have adviſed him to ſow it late in the Spring, it ſhould riſe ſoon, or he ſhould be prepared for its lying longer in the Ground, by knowing it would do ſo, that he might ſow it ſomething ſooner. Gardeners know that old Seed, though good, always lie longer in the Ground than newer of the ſame Kind, and this is particularly ſo in Aniſe.

Therefore let the Huſbandman be very careful in examining the Seed he buys; the beſt Rule that can be given him is, that its Weight and Cleanneſs are Tokens of its being ſound, and the Brightneſs of its Colour ſhews beſt its being new.

The Land being prepared, as we have directed, the Seed is to be ſown lightly and ſparingly over it; and when it is come up it is to be hoed by the Hand Hoe, the Hoers cutting up ſuch Weeds as have riſen among it; and thinning the Plants to about ſix Inches Diſtance every Way.

In this Condition they are to ſtand till they have flowered, and the Seed is ripened; and the Time for gathering them is juſt when it begins to harden.

The beſt Way of gathering this Crop is by pulling up the Plants by Hand, for they root very ſlightly; after which they are to be houſed, that they may dry without waſte, and the Seed is then to be thraſhed off for Sale.

CHAP. XCV.

Of Caraway Seed.

THIS Seed is as well known as Aniſe, and it grows upon a Plant ſomewhat reſembling it in its general Form. It may be cultivated in England in the ſame Manner as Aniſe, but with leſs Charge and Hazard, for it is hardier; and it yields the greater Advantage, as it does not periſh when the firſt Quantity of Seed is ripened, but lives ſeveral Years, producing ſucceſſive large Crops.

The Method of raiſing it is much the ſame with that we have deſcribed for Aniſe, but eaſier; and we have therefore given the other firſt, that the Farmer who ſhall not chuſe to attempt that, may be acquainted with every thing neceſſary to be known about this, which he will leſs fear.

The Caraway Plant grows four Foot high; the Root is long and white, and is of a pleaſant Taſte. The Leaves which riſe from the Root, are large and very finely divided. The Stalk grows up in the Midſt of theſe, and is hollow, ſtriated on the Surface, and divided into a great many Branches. On theſe ſtand Leaves like thoſe that riſe from the Root, only ſmaller, all divided into very narrow and fine Parts: at the Tops of the Branches grow Tufts or Umbells of white Flowers; after which come the Seeds, growing two together. The whole Tuft has no Leaves about its Bottom, nor have the ſingle Flowers any Cup, except ſo ſmall a one as is ſcarce obſervable: in theſe Particulars, as well as in its general Growth, it agrees with Aniſe. Each Flower is compoſed of five little Leaves, which turn back at the Extremities. In the Center of each riſe five ſlender Filaments, each having a little Button or Head, and among theſe grow up two fine Threads, which are the double Style of the Flower; after the Flower is fallen the Seeds grow two cloſe together, and ſeparate when they ripen. There are two or three other Kinds of the Caraway Plant, named by Writers on Botany, but only the common Sort, which we have here deſcribed, is worth the Huſbandman's Notice.

The proper Soil for raiſing it is a deep, rich, mellow Earth, the more like Garden Ground

the better. If there be ſome Sand among it, provided that be not in too large a Quantity, it is not the worſe, wherefore a rich Loam will do; but in general, the richer the Soil the greater will be the Produce.

To prepare this Land for Caraway it ſhould be plowed up in Autumn, and again in the Beginning of February: a Week after this it is to be harrowed carefully, and laid even, and then it is ready for ſowing.

Caraway Seed is plentiful enough, and cheap enough, but let the Farmer ſee he buys ſuch as is ſound and good.

The Quantity that is neceſſary is ſeven Pound to an Acre. When this is ſown as evenly as can be, it is to be harrowed in, and then left to ſhoot.

When the Plants are about three Inches high, the Hoers are to be ſent into the Ground, but they muſt, both in this and Aniſe, be well inſtructed firſt in the Appearance of the Plants themſelves, which otherwiſe they will be very apt to cut up among the Weeds.

They muſt hoe up the young Growth of Weeds that will be now found among the Caraway, and thin the Plants themſelves where they are too thick, taking up the pooreſt, and leaving the others at about eight Inches Diſtance every Way.

If this hoeing be carefully done, it will be of prodigious Uſe to the Crop. The Plants will thrive after it in a very ſurpriſing Manner, and they may be, for the future Part of the Summer, left to themſelves, for they will get ſo much Strength before a new Crop of Weeds riſe, that they will have no Chance among them.

The Crop is not to be expected the firſt Summer. Some of the Plants will run up to Seed, and if ſo many do as are worth cutting, it may be done, but often 'tis otherwiſe; ſo that the Farmer muſt not lay his Account to have a Crop the firſt Year.

The Field is to lie the whole Winter untouched: in Spring it is to be hoed again, and the ſame in August, and ſoon after this laſt hoeing the Seed will ripen. There will be a very large Crop, and the ſame for three or four ſucceeding Years, which is to be cut up, dried, and thraſhed for Sale.

Having thus treated of the ſeveral Particulars under this Denomination, we ſhall give a few general Chapters on the great Article of ſowing, and with that cloſe the Account of Tillage and its Objects.

CHAP. XCVI.

Of Sowing.

IN the Article of Sowing two Things are to be conſidered, the Nature of Seed, and the Temper and Quality of the Ground. Some Kinds of Seed will bear Wet, others will be injured by it; and ſome Land is fitteſt for Sowing when wet, other Kinds when dry.

It is a Rule among the Gardeners to ſow dry and ſet wet, but this will not hold altogether with the Huſbandman. His Fields are a larger Garden, and he muſt not be confined to ſuch little or narrow Rules.

As to the Temper of the Ground proper for Sowing, that depends upon its natural Condition, all Lands ſhould have ſome Moiſture when ſown, but the drieſt ſhould have moſt.

A Land naturally moiſt may be ſown in any Weather, but dry Soils may be ſown in Weather that is very wet, provided the Seed be one that will bear wet.

Wheat ought be ſowed when the Earth is moiſt. This is an Exception to the Gardener's Rule, and it is the moſt important Article in the whole Profeſſion. It can hardly be too wet for the Sowing of Wheat, for this Seed not only will bear wet but requires it: on the contrary, Rye, as we have ſhewn, cannot bear it, nor requires its Aſſiſtance. Rye cannot be ſown too dry: it always thrives ſo much the better.

Rye that is ſown upon the drieſt Land, and in the drieſt Seaſon, will come up without any Rain; but Wheat will lie as if it were dead in the ſame Weather.

The Farmers obſerve the Seaſon of the Year for Sowing, and when that is come they get in their Wheat be the Weather what it will, for this Reaſon it ſometimes will lie ſix Weeks in the Ground without any viſible Shoot, but the firſt good Rains bring it up, if they come in Time: if not there is but a poor Appearance, for often half, or the greateſt Part, will ſpoil with ſo long lying in the Earth.

Let the Farmer in this, as in all other Things, follow Reaſon and Experience, rather than a blind Cuſtom. Let him uſe the common Seaſon for Sowing his Wheat, if the common Weather happen in it; if not let him ſtay beyond that Time. Thoſe who fixed the Time of Sowing Wheat, did it becauſe Rains uſually fall at that Seaſon; if any Year it ſo happens that they do not, let him wait till they have fallen. He will thus better obſerve the Senſe of the antient Rule, than thoſe who ſtick to the Day.

Wheat is not the only Kind that requires Moiſture: but moſt ſucceed very well; nay many of them beſt without it.

Black Oats require as much Moiſture as Wheat, therefore let the Farmer never ſow them but in ſuch a Seaſon: on the other hand, Barley does very well in a dry Time, and all the Summer Corn in general.

Nature takes Care of the Seeds of wild Herbs. They fall at any Time when they are ripe, and be the Seaſon what it will they grow. Some are loſt but enough remain. This is plain, becauſe no Kind of Plant whatſoever has been loſt ſince the Creation. We read in very old Authors of the Herbs of old Time, they do not mention a great Number, but all they have deſcribed diſtinctly, are found to this Day.

The later Writers have been more curious in ſetting down the Names and Figures of a vaſt Variety of others, and in the ſame Manner all they have named continue in their Places; or if they are loſt in one, they are found in another.

Theſe are ſown as Accident directs, and they ſucceed; here is no Regard to wet or dry, yet they proſper. This is true, but let it not miſ-

lead

lead the Farmer. Far from too much, there is too little Care taken in the Sowing of Corn, let him be doubly aſſiduous not remiſs; theſe Plants which Nature ſows at random, are only to keep up the Species.

The Wheat ſown by the Huſbandman is to be conſumed in Food in the far greater Part: and after it has fed Millions, enough is to remain for keeping up the Species. This is a great Difference, and requires all his additional Care.

It may be ſaid in the ſame Manner, that the Earth does for theſe Seeds of Herbs that are wild, without Tillage, or any careful Manner of placing them in the Ground; they fall as Chance directs, and yet they grow. The Anſwer is the ſame, that a ſmall Supply only is wanted from them, therefore this caſual Way of Sowing is enough; if much of the Grain were required for other Uſes, then Care and Culture would be needful.

The Creator of all Things ſaw at firſt the Condition of Wheat, and the other Grains He intended for the Support of Man's Life, and He knew they would therefore have his Care and Labour for their Production. The others which were of no ſuch immediate Uſe or Value He foreſaw would be taken little Care of, He therefore provided for their ſucceeding of themſelves. Proviſion is made accordingly, and it is wonderful in what various and elegant Manner.

They are in general incloſed in a Caſe, ſerving as a Womb, in which they are retained till in perfect Maturity, and which then opening diſcharges them to the Ground. They therefore do not fall till ripe, and fit for growing; and they are ſuited to preſerve themſelves in a proper State, and keep in a proper Place, in a ſurpriſing Manner. Thoſe intended to root about the Mother Plant are ſmall and heavy, ſo that falling they take Root at once, this we ſee in Henbane, and many others. Thoſe which are intended for ſpreading are winged with Down, as thoſe of the Thiſtles. Such as by their Lightneſs would be carried away by every Puff of Wind, have Hooks and Prickles to detain them, as Seeds of Clivers, Avens, and Burdock. Agrimony Seed alſo is rough, ſo that it lays hold of any thing. Many of theſe are intended for the Banks of Fields, where they could not lie but for theſe Hooks and Prickles, that ſerve to keep them in their Places. The Seeds of ſome, which are to be ſcattered at a Diſtance, are lodged in Caſes or Fruits, that toſs them out by their ſpring in breaking, ſuch as Wood Sorrel and the wild Cucumber; and ſome, that they may not riſe in Cluſters together, have a Kind of Wings by which they are influenced by the Wind, to move about upon the Ground; the Fruits of ſome Trees are of this Kind: the Aſh Key and the Pine Kernel are an Inſtance. As this provides againſt thoſe Trees riſing cloſe to one another, in which Caſe they could not thrive, ſo the other is generally given where there is a creeping Root. Wood Sorrel runs a great Way in the Ground by the Root, and therefore this ſcattering of the Seeds to a Diſtance is more uſeful.

Though theſe, and the Generality of wild Herbs, take their Chance as to the Weather, and yet ſucceed enough to preſerve their Species, yet there are ſome that require to be ſown only in peculiar Seaſons. Thus blue Gentian will not ſucceed unleſs ſown when there is wet, but Nature has provided accordingly, for the Seeds are lodged in a Caſe that hold them firm in dry Weather, but ſplits at the firſt Drop of Rain that falls upon it.

Thus we ſee Nature provides for Weeds by various Means, though they be little regarded. Corn is left to the Care of Man, becauſe of its Value, let him not therefore neglect it. It requires a particular Caution and Attention, as well as Labour, to raiſe it, but the Trouble and Expence are well returned. He who underſtands beſt how to employ his Labour will have the beſt Crop.

Nothing is more ſlightly or inconſiderately done than the Sowing in the common Way. We ſee that a certain Time of the Year is fixed upon for doing it, without regard to the Weather, which ought to be the chief Point in View on that Head; and in the uſual Way of doing it the Seed is ſcattered at Random, from the Hand of an unſkilful Perſon, and covered very unequally. It falls too thick in ſome Places, and too thin in others: and in ſome it is buried ſo deep it cannot riſe, while in other Places it is burnt up by lying naked on the Surface.

Inſtead of employing that judicious Care ſo needful in the ſowing Corn, Man here ſcatters it more at Random than the Seeds of the worſt Weeds fall by Nature.

Every Seed has its proper Weather for Sowing its proper Thickneſs upon the Ground, and its proper Depth at which to be covered: theſe are the three great Articles in Sowing. We have ſhewn the Regard that is to be had to the Weather, for the different Kinds; and the Rules by which their Depth and Diſtance may be found. ENGLAND had great Obligation to that Earl of CASTLEMAIN who brought over the original Drill Plow, or Sembrador, from SPAIN; and the World has great Obligations to LEUCATELLO, who invented it; but their Services would have been of little Uſe if not of late revived by Mr. TULL. They had ſlept may Years, and would have been altogether loſt and forgotten. His Praiſe therefore is no leſs than that of the Inventor or Importer of the Machine.

CHAP. XCVII.

Of the Nature of Wheat Seed, and the particular Manner of ſowing it.

THE Reaſon why Wheat requires a particular Care, and a particular Seaſon for the ſowing is, that it is a tender Grain. Rye is hardy, and therefore will ſucceed, as we have ſhewn, under the ſame Condition wherein Wheat will come to little.

Of all our Grain Wheat is leaſt able to bear the Severity of Cold; and yet from its Time of Growth 'tis neceſſary to ſow it before Winter. It has therefore all that hard Seaſon to get thro', and this is the Difficulty.

As it muſt live through the Winter, the Farmer

mer is to defend it as well as he can againſt the Cold, which it is ſo ill able to bear; and the beſt Way he can do this is, by taking Care that the Earth lie hard about it during that Seaſon. this is in a great Meaſure provided by ſowing it in wet Weather, the Soil then cloſing and caking about it; but this brings on another Difficulty. Wheat, of all Corn, requires the moſt Nouriſhment; and we know it cannot ſearch for it by the Roots, unleſs thoſe Roots can ſpread; nor can they do this except the Ground be properly looſe and free. Therefore, as the Condition of Wheat requires the Ground to be compact about it in Winter, ſo it requires it alſo to be looſe in Spring. This is very difficultly to be managed in the common Way of Huſbandry, but it does very well in the drilling and horſehoeing. The Depth at which it is let in by the Drill, gives the Earth Opportunity to cloſe about its Roots, and defend it from the Froſts; and the breaking the Ground between the Rows, by hoeing in Spring, divides the Soil, and makes Way for them to paſs in Search of Nouriſhment.

Therefore the Drill and Horſehoeing Huſbandry is moſt of all ſuited to Wheat, which is the moſt valuable and profitable Grain; 'tis fit the Huſbandman perfectly underſtand the Nature of this capital Grain, if not he will forfeit half the Profit of his Harveſt by the Sowing. There are general Rules for Sowing which hold true in moſt Caſes, but Wheat is an Exception to others of them, beſide that we have named.

'Tis a Rule to ſow on the Ground as ſoon as 'tis plowed, that the Seed may have the Advantage of the freſh Tillage. This to moſt Kinds is very great; but with Wheat another Method is to be followed.

Let the Land be plowed when it is dry, and let it lie till there come Rains to wet it. 'Tis proper to wait for this Advantage, though the Earth lie three Weeks before Sowing, after the Plowing.

If the Land be a ſandy Loam, the clayey Part of which is binding, 'tis beſt to ſow it dry, as well as plow it in that Condition. In this Caſe let the Sowing come directly after the Plowing.

Theſe are the general Rules, but let them be underſtood with Diſcretion: though the Ground ſhould be plowed dry for Wheat, it ſhould not be ſo dry that the Duſt ſhould fly; and though it ſhould be drilled wet, it ſhould not be like Haſty-Pudding. Moderately dry and moderately wet is what we mean by the Direction, but it will bear an Exceſs better in the former than the latter.

The Difference between Ground broken wet and dry, may be ſeen in Banking. A Bank made of wet Earth will keep firm many Years, when one of the ſame Ground dry will moulder continually.

Let the Seed Time be deferred till the Ground is ſufficiently wet, and the dry plowed Land will never fail to produce larger Crops than the wet.

The Conſequence of Plowing wet is almoſt equal to that of Banking; a Piece of Land plowed wet in NOVEMBER, will be harder in Spring than one plowed dry in AUGUST. All Ground grows hard by lying, and naturally the longer the harder; but this Effect of wet out-does that of the Time, though there be a Third of the whole Difference.

When the Land that has been plowed dry is wet enough for Sowing, let it be once harrowed lightly, juſt to level it, and then let it be ſown.

Wheat may be drilled any Time between Harveſt and NOVEMBER, but in general 'tis better to drill earlier than thoſe who ſow in the common Way, than later.

When Wheat is ſown early leſs Seed is required, when later more. Poor Land ſhould have more Seed than rich, becauſe more of the Plants will be deſtroyed on the poorer Land in Winter. Beſide the Plants thriving better on rich Land, will have each more Stalks, ſo that one of them will be equal to many on poor Ground.

CHAP. XCVIII.

Of the Proportion of Seed Wheat to the Land.

THE Quantity of Seed Corn ſowed in the new Method of Huſbandry is a very conſiderable Article in its Recommendation; the proper Quantity for an Acre of middling Land is from four to ſix Gallons; this will ſurprize ſuch as are not uſed to this Huſbandry, but the very ſmalleſt Proportion here named is often ſufficient.

If the Land be rich, and be ready for drilling early, four Gallons of middling Seed will be enough. The Danger of drilling it too thick is, that it will fall; and when too thin the Quantity is often diminiſhed yet farther, by its blighting in Spring. When it is planted early leſs ſerves, becauſe it is more ſafe; that which is drilled late being found, by all Experience, more liable to Accidents from Worms and many other Cauſes.

Where there is Danger of Worms the proper Caution is to plant it ſhallow. Wheat will come up if covered three Inches deep, and it will ſtand very well if not deeper than an Inch; therefore let the Farmer proportion the Depth to the particular Circumſtances and Seaſon of his Sowing. The Way Worms deſtroy Wheat is by eating off the Thread that is continued from the Grain to the Blade. Worms lie deeper in Winter than at other Seaſons, by Way of defending themſelves from Cold, therefore when the Corn is drilled ſhallow they never come near that Thread.

As the Quantity in the Drill Method is much leſs than in the common Way of Sowing, the more Care muſt be taken that it be preſerved. We have ſhewn how it will beſt eſcape Worms; but the Rooks are great Deſtroyers, they muſt be kept off the Land about the Time of its firſt ſhooting. This is the only Period when they are dangerous, but they are very deſtructive then. Boys muſt be employed to fright them away. The Farmer muſt not ſtay till he ſees the Blade up, before he ſets on his Guard. It is true the

Rooks

Rooks will not meddle with it till it has ſhot, but they will ſee this before the Owner. They are ſharp eyed, and juſt when it peeps above Ground is the Time they devour it. They tear it up for the Sake of the Seed, which is then plump and full: when the Shoot has been up a few Days the Flower of the Seed is exhauſted, and they will not meddle with it.

That Wheat is ſafeſt from Rooks which is planted neareſt the Harveſt Time, there is then a great deal of Corn ſcattered on the Ground, and they feed well. While they have Plenty of this they will never look for the other, but when hungry they are very bold and very cunning.

CHAP. XCIX.

Of ſowing Turnip Seed.

WE have obſerved that about MICHAELMAS is the beſt Time for ſowing Wheat. Much ſooner it cannot be ſown; and it is not prudent to do it a great deal later. In Turnips we are not to be particular to a Time. They may be very well ſown from MAY to AUGUST; and in this the Farmer is to guide himſelf by the Nature of his Land.

In a moderate Piece of Ground, MIDSUMMER, or a Week before, or a Week after, is the beſt Time; in poorer Land they ſhould be ſown ſix Weeks ſooner, and ſuch as is in very fine Condition for them it may be let alone till ſix Weeks later. Experience ſhew that Turnips, on a very good Field, will be as forward if ſown at this late Time, as on a poor one at the earlieſt.

As to the Quantity of Seed, we have obſerved on another Occaſion, what a vaſt Difference the Drilling makes from the common Method; four Pounds is often allowed to an Acre in the common Way, and in the Drilling Method four Ounces is full enough.

In the Drill Method Wheat may be ſown upon the ſame Piece with Turnips; and this is to be managed thus. The Turnips muſt be ſown early, they will then be well grown by MICHAELMAS; and that is the Time for ſowing the Wheat. The Turnips being in diſtant Rows Wheat may be ſown between them, the Earth being properly broke for that Purpoſe. Almoſt all the Earth may then be taken from the Turnips; and thus they may ſtand with the Wheat during the Winter. In Spring they are to be pulled up, and the Wheat is then to be left to take all the Advantage of the Ground till Harveſt.

CHAP. C.

Of ſowing Beans.

THE Seaſon for ſowing Beans is FEBRUARY, and the moſt proper Earth is ſuch as is ſtrong, and will retain ſome Wet. The Spring Rains follow this Sowing, and the Crop ſeldom fails unleſs for want of a due Moiſture, ſo that it muſt be an unnatural Seaſon alone that can prevent their thriving if thus ſown. Provided they have this Advantage they get a good firſt Shoot, and no Weather that comes afterwards can hurt them; the richer the Land the better for Beans, provided it have this Firmneſs to hold the Wet. The richeſt Soil will not anſwer without this Quality, for if they ſhoot well at firſt they will be loſt if there come a dry Summer. A loamy Field, with ſome good Mixture of fine Earth, is the proper Place for this Crop, few know the Value of Horſe Beans for want of underſtanding the proper Soil, Seed Time, and Manner of ſowing them; we ſhall endeavour to inſtruct our practical Huſbandman on each Head, from the Reſult of Experience.

We have mentioned the Improvement of clayey Soils by Sand, in the Beginning of this Work, a Soil ſo altered and amended becomes a Loam of the beſt Kind; theſe Clays ſeldom fail to have rich Earth among them, and though in their original and natural States they locked it up, and it was of no Advantage, yet when thus divided by the Sand, broken by Tillage, and calcined by the Sun and Air, from frequent turnings, they become a very rich and very ſtrong Land, and they are able to retain a great deal of Moiſture: theſe therefore are the very beſt Soils for Beans. The next to theſe are ſuch as by Nature come neareſt them; that is, ſuch as are loamy, with a good Mixture of Mould among them.

Let a Field like this be choſen for Beans, let them be ſown the third Week in FEBRUARY, and if they have the Advantage of a dripping Spring, the Crop ſhall be equal in Value to one of Barley.

We have ſhewn what is the great Advantage of Horſehoeing to Wheat, in the cauſing a great Number of Stalks to riſe from one Root, and each to have a great deal of Corn. The ſame Effect is produced by this Practice in Reſpect of Beans. I have counted ninety-five Pods upon one Stalk, all well fed and full of Seed well nouriſhed; and a common Number is ſixty or ſeventy on a Stalk when thus managed. In this Caſe the Land cannot eaſily be turned to a better Account. As loamy Soils are the beſt for Crops of Beans, ſandy are the worſt, yet there are wet Sands that have ſome Clay in their Compoſition, though not enough to get them the Name of Loams, that ſucceed very well with this Growth; in theſe Caſes the Seed ſhould be always drilled in Rows at four Foot Diſtance, and a Farmer who manages properly may get a good Crop of Turnips between.

When any one has a Deſire to raiſe Beans upon a Land that is not naturally ſuited to them, he muſt encreaſe the Quantity of Seed, and be particularly careful in the ſowing. Many of the Plants will come to little; and if added to this Part of the Seed be loſt by Careleſſneſs in getting it into the Ground, and the reſt bear but a poor Quantity, there muſt be a miſerable Proſpect. Dry Weather always hurts Beans, and when they ſtand thin it deſtroys them.

When too few Plants riſe the Weeds will come up too abundantly, and when thoſe that come up are not ſtrong, they get Strength and overpower them. On good Land three Buſhels will ſow an Acre, but it is better, when it is any

thing leſs than the beſt, to ſow four, and on Soils that are poor or dry five Buſhels.

There are two Ways of ſowing them in the ordinary Huſbandry, by the broad Caſt and plowing them in; for this the Seedſman follows the narrow Wheel Plow, and throws in the Seed from his Hand in a direct Line, all the Way along the Furrow: this is called ſpraining them in. The Furrow is left open in this Way by the Plow, but the next turn covers it, and the Beans are buried to a good Depth.

Another Way of ſowing, or rather planting Horſe Beans is by Hand, and it is practiſed in ſeveral Parts of England, at a very moderate Expence, Women do it, and the Method is this.

The Land is plowed light, and the Women draw Lines in it at a Foot and half Diſtance. They have an Inſtrument they call a Dibble or Dibber in their Hands, and Beans in their Apron, and they work by the Line; the Dibber is an old Spade Handle cut off to five Inches length, and tipped at the Point with Iron. They have this in their right Hand, and they take out the Beans from their Apron with their Left. They ſtrike the Dibber into the Ground, and drop a Horſe Bean into the Hole. They thus plant the Beans at about three Inches Diſtance, in Rows eighteen Inches aſunder. This is a very proper Poſition, and a very regular Method of planting them, and 'tis done with ſo much Eaſe that the Expence is very moderate.

When the whole Field is planted they go over it with a Harrow, which ſufficiently covers the Beans; and then they give them two Handhoeings before Harveſt. This is very nearly of kin to the Drill and Horſehoeing Huſbandry, but it is not equal to it in Advantage, as we have ſhewn; for this Handhoeing only ſcratches the Surface of the Ground, whereas the other tears and breaks it to ſuch a Depth, as to invite the Roots of the Crop where the Nouriſhment is moſt abundant.

In Wiltshire they plow only lengthwiſe, never acroſs, and ſow their Beans by the broad Caſt twice in a Place, they then harrow them in, and ſo leave them to their Chance.

In other Places they don't harrow till about the Time when the Beans are juſt going to ſhoot, then they go over the Ground carefully with the common Harrow. This tears up the young Growth of Weeds, and breaks and divides the Ground at the Surface, covering up the Heads of the Beans; immediately after the Harrow they draw over a moderate Roller, which fixes the Earth at the Surface, and levels all for the Scythe at Harveſt.

The Drill Method of ſowing is beſt of all, and the Diſtance between the Rows not only gives Opportunity for Horſehoeing, which vaſtly ſtrengthens the Growth, but the Plants having a free Paſſage for the Air to their Bottoms, bloſſom and bear Fruit all the Way down. This vaſtly encreaſes the Quantity, and at the ſame Time ripens them better.

Though the Horſe Bean is what the Farmer means whenever he talks of his Bean Crop: yet this is not the only Kind that is cultivated in Fields, they ſow five other Sorts in the ſame Manner about London, and in other Places where there is a large Demand, for the ſupplying of the Markets; theſe are the Windſor and Sandwich, the Broadſtock, the Liſbon and the Hotſpur, this laſt is a ſmall Bean, but is valued for its early Time and good Flavour.

There is alſo another Kind that is very properly brought into Uſe of late, and ought to be introduced univerſally; and this is properly the Country Farmer's Concern: this is the Tick Bean, it is properly and truly a Horſe Bean, but it is much broader than the common Kind, and anſwers better on every Occaſion. This is beſt planted by Hand with the Dibber, and the Rows ought to be at leaſt two Foot aſunder, it yields vaſt Crops.

The common Method of managing theſe is by the Hand Hoe, and it does a great deal of Service, though nothing equal to what would be by the Horſehoeing. They give them two Hoeings in this Manner; when they firſt ſhoot up they come in with the Hoe, and cut up all the Weeds between the Rows, and at the ſame Time earth up the Beans: then, when they are about ſix Inches high they come in and hoe them up again, this ſecond Earthing is of great Benefit to the Beans, and the Weeds being deſtroyed at this Growth, are rarely troubleſome again.

Some have ſuppoſed, from hearing the Huſbandmen of other Counties talk of ſmall Ticks and large Ticks, that there were two Kind of Beans of this Denomination, but this is not the Caſe. There is but one Kind of Bean properly thus called. It is a Horſe Bean of the Size of the Hotſpur Bean, and is hardy and very fruitful. What ſome call the ſmall Tick is only the common Horſe Bean.

The Tick Bean is more hearty and nouriſhing than the common Horſe Bean, but as it is larger it requires longer drying. When this is done imperfectly in the Field, the Way is to finiſh it on a large Floor in an airy Place, or in a Kiln. The ſafeſt Method of keeping them is to ſplit them and dry them afterwards; in this Caſe they are never liable to any Accident. They mix excellently with Oats, Chaff or Bran, and are of the greateſt Service to the Cattle.

There have been Times when Bean Bread was eaten for want of better Flour, and no Harm ever happened from it: on the contrary, it was found to be more ſtrengthening than any other.

From what we have here laid down from repeated Experience, let the Farmer learn the Value of a Crop of Beans; but at the ſame Time let him weigh with himſelf the Profit he will have from other Crops, and the Condition of his Land. Let him beware that he is not led away by the Benefit of any one Kind, but chuſe the beſt.

End of the Ninth Book.

A COMPLEAT BODY OF HUSBANDRY.

BOOK X.

Of the natural and artificial Products of the Farmer's Stock.

CHAP.

1. *Of Milk, and its natural Production.*
2. *Of the Nature of Milk.*
3. *Of the ſeveral Kinds of Milk.*
4. *Of Cows Milk, and its general Differences.*
5. *Of chuſing a Milch Cow.*
6. *Of the Quantity of Milk yielded by each Cow.*
7. *Of the Times of milking.*
8. *Of the Manner of milking.*
9. *Of ordering the Milk in the Dairy.*
10. *Of the Veſſels of the Dairy.*
11. *Of ſetting the Milk for Cream.*
12. *Of ſkimming the Cream.*
13. *Of the Management of the Cream.*
14. *Of Butter.*
15. *Of Churning.*
16. *Particular Rules relating to Churning.*
17. *Of the waſhing and making up of Butter.*
18. *Of making Butter from new Milk.*
19. *Of ſalting of Butter.*
20. *Of Whey Butter.*
21. *Of the Uſe of the Barrel Churn.*
22. *Of Cheeſe.*
23. *Of the Rennet or Cheeſe Bag.*
24. *Of new Milk Cheeſe.*
25. *Of a one Meal Cheeſe.*
26. *Of ſkim Milk Cheeſe.*
27. *Of Cheſhire Cheeſe.*
28. *The Way in which Cheſhire Cheeſe is made.*
29. *Of making Cheeſe like Cheſhire in other Places.*
30. *Of making Sheeps Milk Cheeſe.*
31. *To make a Nettle Cheeſe.*
32. *To make a running Cheeſe.*
33. *Somerſetſhire Cheeſe.*
34. *Of ſeveral other Kinds of Cheeſes.*
35. *Of Wool.*
36. *Of Leather.*

The INTRODUCTION.

WE have conſidered in a preceding Part of our Work, that important Article of ſtocking the Farm, and have acquainted our Huſbandman with the ſeveral Breeds of thoſe Animals which he is to feed upon its Produce for Labour or Profit.

We have ſuppoſed him provided, and have ſince gone through thoſe ſeveral Articles by which he is to procure them Food, and in which he is to uſe their Service: this done, we come in the preſent Book, to treat of thoſe Benefits he receives from them in their ſeveral Products, and the beſt Manner wherein he is able to uſe them to his Advantage.

We divide them into natural and artificial, as they are of two Kinds, properly coming under thoſe two Denominations; one part of them ariſing naturally, and being uſed in the Condition in which he receives them; the other requiring Art and Management to bring them into the State that is fit for Sale.

Of the firſt Kind, or natural Products of the Stock, are Milk and Wool; theſe he receives from the Udder, or ſheers from the Back; and he

he may ſell them as they are, that is, in their natural State and Condition; of the artificial Kinds are ſeveral Things ariſing from the Uſe or Manufacturing of the former. Thus Butter and Cheeſe, though originally owing to Milk, yet are not obtained without manual Labour and Art. Theſe we call the artificial Products of the Stock; and under the one or other of theſe Names, we comprehend the whole Produce from theſe Animals, according to the Manner in which it is obtained from them.

We ſhall treat of theſe ſeveral Subjects largely, though in as few Words as the Nature of what we have to ſay will permit. Many uſeful Things there are which the Farmer yet does not know relating to theſe Articles; nor ſhall we omit Matters of Curioſity relating to them, when they tend to explain and illuſtrate ſuch as are of Uſe.

We apprehend that the Farmer of one Place may be inſtructed by ſeeing here the Practice of the Huſbandman in another. There are many Things alſo written on theſe Matters, from which ſeparating the uſeful from the oſtentatious Part, much Knowledge may be drawn.

We propoſe therefore to lay before our Readers, ſo far as we have been able to collect or learn, the Subſtance of ſome have written, and others have practiſed; and upon the whole to build a Syſtem for the Conduct and Management of theſe important Articles; which the Farmer's Reaſon ſhall countenance, and, we doubt not, his Experience afterwards approve.

CHAP. I.

Of Milk, and its natural Production.

IN treating of Milk, the firſt Thing needful is to conſider what it properly and truly is, for on that will be rationally founded all that is added concerning its Uſe.

Milk is a Fluid ſeparated from the nutritious Juice of Bodies, called their Chyle; depoſited by Nature in the Breaſts or Udders of Female Animals, during their Pregnancy, and for the Nouriſhment of their Young.

After the Young is born it comes in greater Abundance: and it will be prepared and furniſhed by Nature in that plentiful Manner, ſo long as it is ſucked by the Young, or any other Way drawn at Times; but when no Uſe is made of it, the Supply ceaſes; and the Milk, as the Expreſſion is, dries up of itſelf.

We have mentioned the Breaſts and Udders of pregnant Females as the natural Place for Milk; but the Curious have diſcovered, and ſometimes Accidents have ſhewn, that it is not limited to that Sex, or that State; Male Creatures, both Human and of the Brute Kind, have had Milk; and among the Females, ſuch as have not been in a State of Pregnancy.

The Roman Charity ſo famous in Hiſtory and Paintings, is an Inſtance of the latter in the Human Species; wherein an old Man confined in a Dungeon, was ſupported with Nouriſhment by ſucking the Breaſts of his Daughter a Virgin.

As to the former Caſe, Accidents have from time to time rendered it notorious; ſo long ſince as the Time of ARISTOTLE, it was known that ſome Men had been found to have Milk in their Breaſts: and CARDAN upon his own Knowledge relates the ſame, averring that there was ſuch a Quantity, that a Child might be nouriſhed by it. PLINY relates the ſame of a Man in his Time, and ALDROVAND of another. Theſe Authorities ſo numerous are not to be doubted; nor is the Thing confined to the human Species in this Inſtance: we have a circumſtantial Account in the Philoſophical Tranſactions, of a Weather Sheep giving ſuck to a Lamb; and that not wantonly or for once, but in a regular Quantity, and enough for the Support of the young Creature many Months.

Wonderful as all theſe Accounts may appear to thoſe not uſed to conſider Things in their Cauſes, there is not in Reality any Thing ſo ſtrange in them, when the Matter is fully weighed.

Nature has provided Breaſts and Udders, with their Teats and Nipples, for all Females, younger as well as grown up; and to the Males ſhe has given the ſame Parts, by way of Conformity in the Species, though not intended for the ſame Service.

Milk is a natural Juice, and although prepared regularly at a certain Period, yet being formed from the Nouriſhment of the Body, it may be produced at any other; and as the Nouriſhment of Men is the ſame with that of Women, there is no Reaſon why it ſhould not, if wanted, be ſupplied by one as well as the other.

We ſee in the common Courſe of Nature, that ſucking will make it continue to flow when it otherwiſe would have dried up; and there is not much more wonder that the ſame Force ſhould bring it to a Place naturally deſtined for it, even at a Time when it would not otherwiſe have come.

This Method of reaſoning, plain and familiar as it is, will very well explain the Breaſts of Virgins affording Milk on being ſucked; and we ſhall not, upon a like rational Enquiry, find it any Thing more ſtrange, that the ſame Force ſhould bring it into the Breaſts of the other Sex, whether in Human or Brute Creatures.

We ſee in Men the Texture of the Breaſts is not very unlike that of Womens, and the Nipples are of the ſame Structure entirely. We have no Reaſon to ſuppoſe the Reſemblance ſtops here. Indeed Anatomy ſhews that it does not, and therefore as the Parts are of the ſame Structure, and there is the ſame Nouriſhment for the Purpoſe, it is not ſtrange that ſucking ſhould produce it.

The moſt plain Reader may underſtand theſe Reaſonings; and ſo it is throughout all Nature: hard Words are only Cloaks for Ignorance. We believe it will from this appear, that far from diſcrediting the Stories, they have heard or read of Milk in Virgins, and Milk in Male Creatures, our impartial Readers will join with us in Opinion, that the Wonder is rather that ſuch Things are not more common.

It is not ſtraining the Point too far to ſay, that

that probably any Virgin grown near Maturity, or any Man in Health, would give Milk if ſucked ſome time for it; and the ſame is doubtleſs equally true of Animals of other Kinds.

This ſeems to be a Proviſion of Nature, careful of all her Productions, as a laſt Reſource in caſe of extream Neceſſity for the tender and defenceleſs Young of Animals, which from Accidents would otherwiſe be loſt.

CHAP. II.

Of the Nature of Milk.

MILK is very much of the Nature of what is called Chyle, that is, the nutritious Juice ſeparated from our Food, and intended for the Support and Nouriſhment of our Bodies. All our Foods tend to the Formation of Chyle, and the great Purpoſe of Nature in their Digeſtion is the furniſhing of a ſufficient Supply of it; for on this Reſtoration and Preſervation of the Fabrick depend.

Chyle is a thin white Juice, conſiſting of the fineſt and moſt nouriſhing Part of our Food; and Milk is properly ſpeaking, nothing more than a thicker and richer Chyle: when the two are compared together, there is found no other Difference between them; therefore we may very reaſonably conclude, that Milk not only is made of Chyle, but that it is made by a very natural and eaſy Procedure; for there ſeems nothing more to have been done than this, that a Quantity of Chyle has been brought into the Glands of the Breaſts, and there ſome of its watery Parts have been ſeparated from it; and the Remainder becoming richer by that Means, has been left there ready to be drawn by the Mouth of the Young, or otherwiſe, in the Form of what we call Milk.

It is not ſtrange that Milk ſhould be thus made by depriving a nouriſhing Juice of ſome of its watery Parts; for upon Examination by Glaſſes, we find that it ſtill conſiſts of only a ſmall Part of real and rich Nouriſhment, mixed with a larger Quantity of a watery Fluid; and what we thus diſcover by Glaſſes, the Progreſs of Nature when Milk is left to itſelf to ſpoil, or when it is managed uſefully in the Dairy alſo confirms; for whether Milk become unmixed, as we may ſay by the Courſe of Nature, or by Management for uſeful Purpoſes, ſtill the ſame Thing is found; namely, a ſmaller Quantity of rich Matter, and a much larger of a watery Fluid.

When Milk is viewed with powerful Glaſſes, it does not look an uniform white Liquor, as it appears to the naked Eye, but is diſcovered to conſiſt of two different Matters; the one white and rich which is kept ſeparate in round Drops, and the other thin and watery: this laſt is the more large Quantity, and the other Drops ſwim in it.

In the ſame Manner when we make Butter and Cheeſe, we force a Separation of thoſe Parts, which we could not ſee to be diſtinct and different in the Milk, though this common Operation ſhews they were ſo: the rich Part makes the Butter and Cheeſe, and the other runs off poor and watery in the Butter Milk and the Whey.

This is a Proof of the Truth of what Mr. Lewenhoeck firſt declared he ſaw by Glaſſes, and it is thus that the common Operations of our Lives illuſtrate the Truths of Philoſophy; while Philoſophy ſhews us the Principles on which they are founded, and will therefore be uſeful to improve them.

The old Phyſicians thought the Milk in the Breaſts and Udders of Animals was formed from the Blood, but that led them into great Difficulties: Nature does not go to work by ſuch round-about Ways; the Proceſs by which Milk was formed, might then well appear difficult to be comprehended; but upon the preſent Plan it is very eaſy. Milk is firſt of all conveyed to the Breaſts in form of Chyle; that is, very nearly in its own proper Form; and as to the Change it undergoes in being ſeparated from ſome of its watery Mixture, 'tis no more laborious, intricate, or difficult, than that of the Separation of Urine through the Kidneys; nothing more is done than the throwing off a watery Part.

CHAP. III.

Of the ſeveral Kinds of Milk.

THE Reader has ſeen that Milk is only a richer Kind of Chyle: he has been informed how it is prepared, and in general of its Nature: to come a little cloſer to that Point, we are to examine it farther.

We have ſeen that it is compoſed of more rich and ſolid, and more fluid and watery Parts; but although the Aſſiſtance of Glaſſes could inform us no farther concerning this Matter, the Operations of the Dairy do.

Philoſophy ſhews us, from its Aſſiſtant Microſcopes, only two Parts in Milk, but Experience diſcovers three.

Milk is found by the Operations of the Dairy, to conſiſt of theſe three Parts; the Buttery, the Cheeſy, and the Wheyey.

The Buttery Parts are thoſe which being of an oily Texture, ſeparate moſt eaſily, and get to the Top. This is found agreeable to all we know in Nature: we find Butter to be of the Nature of Oil, and we know Oil will ſwim upon Water. Therefore we find that theſe three ſeparate Parts of which Milk is compoſed, are of three different Qualities; and by firſt underſtanding them, we ſhall eaſily comprehend all the Operations by which it is ſuited to our various Uſes.

Theſe three Parts are, 1. The oily; 2. The curdy; and, 3. The watery. The oily are, as we have ſeen, the Buttery Parts; the curdy are the Cheeſy, and the watery are the Wheyey.

Nothing but the Force of Nature in the Body of the Animal, could work and blend theſe perfectly into one rich and nouriſhing Fluid, fit for the tender Stomach of the Young. We find they are ſo mixed there; and that they continue mixed in that Manner for ſome Time, after

the Milk is out of the Body; but when they have once ſeparated, either naturally or by Art, we ſhall never be able to mix them ſo again. Butter, Cheeſe, and Whey were all contained in the Milk, and Nature united them in that Manner; but all our Chymiſtry will never be able to mix Butter, Cheeſe, and Whey, into Milk again.

Thus far we have ſpoken of Milk in general, as Milk, not as the Milk of any particular Kind of Creature; but having ſhewn what the Fluid itſelf is, we ſhall now ſpeak of its Differences according to the Creature from which it is obtained.

We ſhall in this Place, remembering that we write for Uſe, not Curioſity; and for the Uſe of the Farmer in particular; avoid all thoſe Things that might be ſaid concerning the Milk of the Human Breaſt, and that of ſuch other Creatures as do not fall under his Conſideration.

We ſhall conſider only the Milk of his Stock, as it may be profitable or ſerviceable to him in its ſeveral States, plain, or made into thoſe artificial Products we have already named.

Milk differs extreamly in various Creatures, according to their Diet, their Conſtruction of Body, and the particular Structure of thoſe Parts in which it is formed.

The firſt and great End of Nature in the Production of Milk, we have ſhewn was for the Nouriſhment of the Young; ſhe knows, or to uſe more proper Words, God whoſe immediate and regular Care in the Guidance of the World, is what we call Nature, knows beſt the Structure of thoſe young and tender Bodies he forms; and he has accordingly provided in the Breaſts and Udders of their Dams, a Nouriſhment ſuited to them.

Thus in all Creatures, Milk is, as we have ſhewn, the Chyle or nutritive Juice of the Parent's Body, formed into that Condition by the Separation of its watery Parts; but in ſome Creatures, more of thoſe watery Parts are ſeparated, and in others fewer, according to the Structure of thoſe Veſſels; and it muſt be according to what we ſee of their Food, that in ſome the Chyle comes more watery to thoſe Glands that ſeparate it, than it does in others: why otherwiſe ſhould it be, that the Milk of the Cow ſhould be ſo rich, and that of the Aſs ſo poor, when both eat the Graſs of the ſame Paſture.

Let not any be ſurprized at the calling Aſſes Milk poor in compariſon of Cows, from an Opinion that it muſt be richer becauſe of the Uſe Phyſicians make of it to reſtore decayed Conſtitutions: 'tis becauſe it is poorer they preſer it, for the Stomach in thoſe Perſons is not able to bear the richer Milk of the Cow.

According therefore to what we ſee in Nature, it is plain that the different Conſtruction of Body, and different Fabrick of the Veſſels formed for ſeparating and preparing Milk, occaſion that Liquor to be richer in ſome and poorer in others. This is all the real Difference between the Milk of one Creature and that of another: having premiſed this, we ſhall proceed to conſider ſeparately, thoſe ſeveral Kinds that any Way come under the Farmer's Conſideration.

Theſe are principally four; the Cows, the Aſſes, the Goats, and the Sheep: a fifth might be added, for the Milk of the Mare is uſed in ſome Places; but the firſt named Kind is the great and principal Concern of the Farmer, and the Support of the Dairy.

Nothing can be more rational than the giving ſuch Milk as Aſſes, and any other Kind that can be borne upon the Stomach as a Reſtorative: For we have ſhewn already, that Milk is only Chyle under a particular Form, therefore when the Stomach will bear it, it is Nouriſhment ready formed, and fit for immediately mixing with the Blood, to anſwer all the Purpoſes of Life.

This is properly a Method of reſtoring Nature: it is coming in to her Aſſiſtance when ſhe is not able to furniſh Nouriſhment, by bringing her that of ſome other Animal ready formed, to ſupply the Place.

As to the Preference of Aſſes Milk above that of the Cow, in the Relief of Human Kind, the Reaſon is ſhewn in Nature. Let the Milk of our own Species be compared with that of a Cow, and that of an Aſs; and the Aſſes Milk will be found to reſemble it much more than the other.

As it is commonly the Misfortune of Perſons afflicted with ſuch Diſorders as require the Aſſiſtance of Milk, to have ſuch ſharp Juices on their Stomach, as turn it to Curd; the Remedy is to ſweeten or take off the Sharpneſs of thoſe Juices: Phyſicians preſcribe various Things for that Purpoſe, but there is nothing equal to Chalk ground to a very fine Powder, and given in a little of the Milk.

Theſe ſeveral Kinds of Milk, and their Value and Uſes, ſo far as they concern the Farmer, we ſhall conſider in their proper Order, beginning with that which many Times exceeds them all in Value.

CHAP. IV.

Of Cows Milk, and its general Differences.

COWS Milk is in general by much the richeſt of all the Kinds we know, and the moſt profitable: its ſeveral Products in Butter and Cheeſe, being like its natural Condition as Milk, preferable to thoſe of all others, not only in Quality, but in Quantity: two Articles which when they concur, as they do perfectly in this Inſtance, conſtitute the higheſt Uſe and Value to the Owner.

The Milk of the Cow is ſuppoſed to vary according to the Colour of the Skin, but this is an idle Obſervation. There is an old Saying among the Farmers, that red Cows give the beſt Milk; and another, that black Cows bring the fineſt Calves: but we can from fair Trial, and repeated Experience, aſſure our Reader that there is not the leaſt Truth in either of theſe Maxims: he is to look upon them as old Wifes Tales, and no otherwiſe. We have ſeen

as

as much and as good Milk from black Cows, as ever was produced from red; and we may call all SMITHFIELD to witneſs, that the Value of the Calf is not in the leaſt dependent upon the Colour of the Cow.

We ſhall inform the Farmer what is the real Difference in Cattle that concerns their Milk, and he will ſee in the Courſe of that Enquiry, what has been the Origin of this idle Opinion.

He may remember that in a former Part of this Work, we have delivered him Rules for the Choice of his Cattle for their ſeveral Purpoſes; in this there is no particular Rule, for the Cow that will, when ſhe is no longer fit for the Dairy, be beſt for the Butcher; will, for the ſame Reaſon, be beſt for the Service of the Dairy alſo, while of a proper Age.

Thus, in general, the Cow to be choſen for the Dairy ſhould be large, big bon'd yet well ſhaped, and of the biggeſt Breed. This was always the Choice of the Cow, and this ſuits her as well for the Shambles as the Pail: when the Breeds of Cattle were kept more entire, WILTSHIRE was the Place from whence this large Kind principally came, and the Breed there was uſually red: from hence it became uſual to call the WILTSHIRE Breed, the red Breed; and thence inſtead of ſaying the WILTSHIRE Cow gave the beſt Milk, People uſed to ſay the red Cow gave the beſt; thoſe two Words ſignifying at that Time the very ſame Thing.

An Error or Confuſion of ſpeaking exactly of the ſame Kind, gave Origin to the vulgar Notion of the black Cow bringing the beſt Calf. The LANCASHIRE Breed were famous for their Calves; and they were generally black: thus a black Cow, and a LANCASHIRE Cow, became two Expreſſions for the ſame Thing, in the ſame Manner, as we have ſhewn a red Cow, and a WILTSHIRE Cow meant the ſame; and thus it was that when they meant to ſay, the LANCASHIRE Cow was the beſt for a Calf, they named the Colour, and not the Place, and ſaid a black Cow.

This has in each Caſe been the Occaſion of a vulgar Error, and there is no more Truth at preſent in the Preference of the red Cows Milk, than in any the idleſt common Saying.

While the Breeds of Kine were kept diſtinct, there was ſome Meaning in it; though in Reference to the Colour, it was only accidental; but now the Breeds are ſo mixed and confounded by introducing one among another, that nothing certain is to be deduced from the whole Matter.

There is another Article which does in Reality make an Alteration in the Milk of Cows, and that is the Paſturage, and Manner of feeding; but this we have, in general, conſidered already. The Reader will find it in our Diſcourſe on the Cow Kind, to which we refer him to avoid Repetition.

CHAP. V.

Of the chuſing a Milch Cow.

WE have in the before mentioned Place, given at large the Marks of Cattle, which are beſt in their ſeveral Kinds; but in this Place we ſhall add for the Service of the Dairy, ſuch Particulars as are of immediate Reference thereto, only mentioning in few Words ſo much of thoſe general Directions as are needful to be remembered therewith.

Having fixed upon a Cow that is large and well ſhaped, let the Houſewife examine whether ſhe be gentle and kindly. This may ſeem trifling, but it is much otherwiſe. There are in theſe Creatures Differences of Diſpoſition, as well as among ourſelves, and it is in vain to think they can be altered; Perverſeneſſes of this Kind are very difficultly conquered in us that have Reaſon, and it is not to be expected they can with Eaſe in ſuch Brute Creatures as want it.

The Cow being a Creature that muſt be always about the Houſe, her Gentleneſs is a very eſſential Point; and if ſhe be of a very unruly Diſpoſition, often it will reduce half her Value.

The principal Marks by which a Cow may be judged to be formed for Plenty of Milk, are a large and handſome Udder, with a proper Number of Teats, which is four, with no additional or ill ſhaped ones; but theſe four all long, thick, and ſmall at the Ends.

After the Udder, let the Neck be examined, this ſhould be thin, and ſhould have a large and hairy Dewlap.

The Horns are by many ſuppoſed to denote a large Quantity of Milk when they are ſhort and crumpled, nor is this Mark to be utterly neglected. The Horns have no real Connection with the Udder, ſo that a Plenty of Milk does not depend upon them; but the beſt Dutch and Alderney Cows have theſe ſhort and crumpled Horns, and they are ſuperior to any other for the Service of the Dairy. The Horn being an eſſential Mark of the Breed in theſe, may therefore be conſidered as a Mark of Plenty of Milk.

When ſeveral Cows are to be purchaſed for the Dairy, it is very material to have them all of the ſame Kind or Breed as nearly as may be; and to take Care the Bull or Bulls, according to the Number, be of the ſame Breed alſo.

We have before obſerved, that the Breeds are at this Time ſadly mixed and confounded in ENGLAND; but as the Number cannot be had entirely of one particular Breed, let them be as near as poſſible of the ſame Make, Size, and Shape, according to the Rules we have laid down: and we muſt here repeat the Obſervation, that the Colour is of no Conſequence: let not the Farmer trouble himſelf to have red Cows for ſerving the Dairy, and black Cows for calving: this will confound the Breed, the red will ſerve for both Purpoſes equally, if their Shape be proper, and ſo will the black; therefore let his whole Care be employed, as we have named already, to have them all good, and all like one another; by this Means they will herd the more kindly together, and he will have a Breed of his own better than what he at firſt purchaſed.

We have one Thing yet to mention, with reſpect to the Choice of a Cow for the Dairy, which is very often in the Houſewife's Mouth,

and

and ſhould be always in her Mind in the Purchaſe. This is what they expreſs by a particular Term, calling it Depth of Milk. By this they mean the Quantity the Cow does, or is like to furniſh: and there are Ways of judging of this, without much Danger of Error.

The Time when a Cow gives the largeſt Quantity of Milk is, when ſhe has newly calved, therefore let the Produce be well examined at that Time; for if it be deficient then, the Owner may be ſure it will never be better.

There are Cows that have more, and others that have leſs Milk; or according to their Expreſſion, Cows that are deeper in Milk, and Cows that have leſs Depth of it, without any viſible Reaſon for it; therefore in this, only Experience can guide.

We have given the Rule, and the Time of judging; and we ſhall proceed to adviſe the Owner to keep or diſpoſe of his Cows accordingly: ſo that by Degrees he will thus exchange or ſell, and purchaſe again, till he have at length not a Cow in his Yard but yields as much as a Cow well can.

This is an eſſential Point, for if the Difference in a ſingle Cow be ſomething, as it certainly is; 'tis very great in the Produce of a Number; and this is a Certainty that the Quantity of Milk does not depend upon the Quantity of Food, though the Quality of it often does upon the Nature of the Food.

A Cow that is ſtarved will not yield much, that ſtands to Reaſon; but if a Couple of Cows be watched, one of which is deep in Milk and the other not, ſhe that is the leaſt profitable, will be found to conſume as much Provender, let it be of what Kind it will, as the other.

CHAP. VI.

Of the Quantity of Milk yielded by each Cow.

THE Reader has juſt ſeen that there is a great deal of Difference in the Produce of Cows for the Dairy, when no particular Cauſe can be aſſigned; and there is alſo great Variation in reſpect of the Age, Time, Breed, and Size of the Cow, ſo that it is not only difficult but impoſſible to fix any Standard or Meaſure of the Quantity a Cow ſhould, may, or ought to yield: yet that the Owner may form ſome gueſs whether his Dairy be ſupplied moderately, poorly, or very well, we ſhall give ſome general Calculations of what may be expected. This is all that can be done in ſuch Caſes; and this, though not capable of being brought to Exactneſs or Certainty, yet is of great Uſe.

Not only the Nature and particular Conſtitution of the Cow, will make a great deal of Difference in reſpect of the Quantity of Milk; but the Time of her calving, and the particular Circumſtances relating thereto. Theſe vary ſo much in different Cows, that they prevent the Certainty of that Rule which we have in general laid down for judging of the Depth of Milk, from the Quantity yielded juſt after calving; and theſe Particularities are to be weighed and conſidered: let not the Farmer therefore think the leſs of that Rule becauſe there may be an Exception to it, from the particular Conſtitution of the Cow; but remember that all general Rules admit ſome Exceptions; and let him judge, both in reſpect of what has been ſaid, and of what we are about to ſay accordingly.

Let him obſerve what Milk his Cow yields ſoon after calving, whether it be more or leſs, and mark her down accordingly; but though he ſet down that which yields a great deal at this Time for Keeping, and that which yields but little for Sale; yet let him continue both in his Yard through the Year, and examine them as they go on.

Often a Cow that gives a great deal at firſt, ſoon falls off in that Reſpect, and yields leſs than another; and there is this farther Difference, that ſome go dry a Month, two Months, and ſome three Months, before they calve again, whereas others will yield their Quantity to the laſt. I have known them do it even the Night before their calving. This therefore is to be conſidered; for the ſame Cow that is deep in Milk once, will continue ſo; and in the ſame Manner, ſhe that one Year gives little, will not be eaſily made to yield more another.

It often happens that one of thoſe which yield a great Quantity when they have firſt calved, will grow dry ten Weeks or three Months before calving again; and on the other hand, that one which yields moderately at firſt, will continue it till the very Day of her next calveing.

Now when a Cow yields but little at firſt, ſhe can never be worth keeping for the Dairy, and therefore ſhould be diſpoſed off at once, and her Place in the Yard ſupplied by one more profitable; but a Cow that yields moderately, though not greatly, and continues it the Year round, may be worth more to her Owner than one of thoſe that yield a great deal at firſt, and grow dry for ſeveral Weeks. This muſt be carefully regarded; for the Value or Preference of one of thoſe Cows over the other, cannot be made without a Computation of the whole Produce for that Length of Time.

While this Obſervation gives the Farmer a Caution not to be too haſty in judging of the Value of his Cows, it at the ſame Time ſets in a clearer Light, the uncertainty and difficulty we have before named, of making any Computation ſtrictly of the Quantity to be expected from a ſingle Cow: we ſhall, however, ſpeak as we propoſed in general to that Point.

A great deal depends as to the Quantity of Milk upon the Time the Cow is to calve; and as this makes ſo great an Alteration in the annual Produce, we cannot ſtate the Account without it.

The beſt and moſt favourable Time for the Cow to calve, in order to her yielding the greateſt Plenty of Milk is, when the Paſturage is ſpringing in all its Strength, for then it will make the greateſt Supply. Therefore thoſe who wiſh for Abundance of Milk, are very happy if their Calves fall in the End of MARCH, or the

Beginning of APRIL, for at that Season the Grass is in its fullest springing Strength. The Calves at this Time indeed are not profitable for rearing, because they must be fed upon the Cow's best Milk, which is not the Case of those that fall latter; but an early Cow, the Calf being considered as to be sold to the Butcher as soon as may be, is vastly preferable in Point of the Abundance of Milk, to one that falls later.

To speak of the Milk in its most favourable Time for Quantity, and under the most favourable Circumstances, we will compute that of a new milch Cow first turned to Grass in APRIL. The Produce of such a Cow at such a Time, according to the different Accidents we have named, may be computed between five Quarts and twelve at a milking; and many of these Accidents have Causes so beyond our Reach to know, that it is often impossible to guess any thing about the Difference before hand. Three Gallons, WINCHESTER Measure, at a Time, is a very great and rich Produce; two Gallons is a very fine Quantity: a Cow that gives five Quarts at a milking, which we have set at the lowest worth keeping, is a very good one, if she will continue it the whole Year round; so that she is worth trying; but the Cow that yields less than a Gallon is utterly to be rejected, and her Place supplied by another. In general, the Cow may be said to yield very well that gives a Gallon and half at a Time, if there be a proper Continuance of that Quantity. If this be properly managed it will yield a sixth Part Cream, that is, one Quart of good rich Cream for every Time of milking each Cow; and this will yield very well a Pound of Butter.

This is the Computation the Farmer ought to receive as a Medium, he may rest satisfied with a Cow that gives less, and he may have one that yields much more, not a great deal to his Advantage; because those great Yielders, as we have observed before, do not hold out like those which begin, as the Expression is, fair and softly.

It will not be difficult, from this moderate Estimate, to compute what the industrious and careful Housewife will make of a good Number of Cows, the Produce is easy from one to many, when the common Quantity is known.

CHAP. VII.

Of the Times of milking.

THE two great Points upon which the Profit of a Dairy depends are the Hours of milking, and the proper ordering of the Milk when it is brought into the House. The first may seem to many a small Concern in Comparison of the other, but those who have had Experience for their Guide know 'tis of great Importance.

A Cow should be milked always twice in the four and twenty Hours: there are those who approve of three Times, but to speak from Experience I must have Leave to say, that it is Trouble employed to Loss; for upon Trial I have found that the Quantity of Milk obtained at twice milking at twelve Hours Distance, has been more than that got by three Times milking at six Hours Distance in the Day, and leaving the Night for Rest entirely.

This last Practice, however recommended by some who have written well on these Matters, and however approved by some who think themselves good Housewives, proves on Trial to be faulty and erroneous: 'tis only a teazing of Nature: 'tis expecting what cannot be performed, for a Supply worth taking, or needful to be taken, cannot be made in less than twelve Hours; and beside, Nature loves Regularity; and in our Way of two milkings in the four and twenty Hours, each may be at twelve Hours Distance; whereas in the other, the common Way is to have two Intervals of only six Hours each, and one of twelve.

Those who understand the Conduct of Nature in the Bodies of Animals, know that there is not this Difference to be made between the Hours of eating and of rest; for though the Creature eat only in the Day, the Work of Digestion goes on all Night, and therefore the Times of milking ought to be at regular Distances: this also is shewn by Experience, because we find a Cow with an Udder full in the Morning after sleeping, as well as in the Evening after the whole Day's feeding.

There are Cows that it is said require three Times milking in the four and twenty Hours, because otherwise they will shed their Milk: this would seem an Objection to what I have endeavoured to establish as a Rule; but from all that I have seen, this Necessity has been owing to nothing in regular Nature, but altogether to one of these two Causes, either to a Custom of doing it, or to some Distemper in the Udder, or in the Nature of the Milk.

Whatever Nature has been accustomed to, that she expects; therefore if a Cow have been used to be milked thrice a Day, she will require it, but the Quantity, as before observed, will not be at all more than if she were milked only twice; as to the other Case, of her shedding the Milk if not taken at these Times, it is to be consider'd as a Disorder, being certainly no other; and certainly what a sickly or distempered Creature requires, is not to be made a Rule for the Management of one that is in Health.

From this, and from all I have seen, and all the Observations I have been able to make from repeated Trials, I am convinced that two milkings in a Day is as much as any Cow in a State of Health can require; and that the greatest Quantity of Milk is obtained under this Management.

Having established twice in the four and twenty Hours, as the proper Periods of milking, the next Thing is to settle at what Time it shall be done. But this is a Thing more liable to Uncertainty than the other. In many Places there are certain stated Hours for the Sale of Milk, and when any considerable Quantity of it is intended to be disposed of in that Way, the Times of milking must be adapted to those Hours: thus in and about LONDON, and other large Towns, there are certain Hours at the which Fa-

milies are uſed to take in the Milk for their Occaſions, they therefore expect it at theſe Times; and the Retailers are uſed to have it at the Hours juſt before; ſo that the profeſſed Cowkeeper, who intends this Uſe of his Milk, muſt accommodate the Times of milking accordingly.

On the other hand, the Country Farmer who keeps his Dairy for his own Uſe and Profit, and ſet the greateſt Part, or in a Manner all that his Cows yield, for Cream, may take what Times of milking he pleaſes; and then it is his Buſineſs to chuſe ſuch as are moſt natural.

In Summer, when the Days are long, the moſt natural, convenient, and advantageous Times are Morning and Evening: no Hours are ſo well as between ſix and ſeven in the Morning, and toward ſeven in the Evening. There are no Hours of the Day at which the Udders of the Cows are ſo naturally diſtended with Milk; conſequently none at which it is ſo natural, or ſo much an Eaſe to themſelves to milk them, or at which they yield ſo freely.

The Morning gives the Milk formed in the whole Night's Reſt and Digeſtion; and the Evening gives that made from the abundant Food of the Day; Part of which, from the Quantity taken in, muſt be converted into Nouriſhment at the Time; the Remainder during the Hours of Repoſe. We have, in a preceding Chapter, informed the Farmer how Milk is formed and produced, therefore this Account will be familiar to him.

As the Days lengthen toward Midsummer, theſe Hours may be made a little earlier and a little later, but not much; as the Days ſhorten after Midsummer they muſt of Neceſſity be changed for ſuch as are conſiderably later in the Morning, and conſiderably earlier in the Afternoon.

As to the third Time of milking, thoſe over-induſtrious Perſons who approve of it, generally make it ſix Hours after the Morning milking, which places it ſix Hours before the Evening Time in Summer, and makes it about the Middle of the Day. We have already ſhewn that it is prejudicial to the Creatures, and of no Advantage to the Farmer; and we may add, that as it requires more Trouble and Attendance of Servants, it neceſſarily brings on more Expence, which is another Diſadvantage.

From what I have ſeen of the milking Cows three Times a Day, I think I have Reaſon to imagine that it makes them dry up the ſooner. I had been led to believe at one Time, that it would be a Way to keep them in Milk the Year round, and made Trials in my own Stock, carefully minuting down the Obſervations, which I expected would have ſhewn this, but the Effect was exactly the contrary: ſo that ſeeing the Matter in all its poſſible Lights, this third milking is a diſadvantageous Practice.

I have met with ſome Farmers who have been ſtrongly of Opinion, that the Cow's keeping in Milk to the Time of her calving again, was not to their Advantage; for that the Milk being drawn away all that Time weakened the Calf. This is another of thoſe ſpecious Reaſonings which nothing ſets aſide but Experience. I have examined and obſerved this Difference in reſpect of the Calves, not once or twice, but many repeated Times, and can aſſure the Farmer, from what I have thus ſeen, that a Cow's yielding Milk to the very Time of her coming again, is no Diſadvantage at all to the Calf that is to come, but rather a Help. From theſe Obſervations what I have learned is this, that a Calf in the Body of the Cow is much more likely to have too much Nouriſhment than too little; and that for one which comes into the World poor and ſtarved, twenty come full of groſs Humours. At the ſame Time it is to be obſerved, that want of Nouriſhment is a Fault ſoon mended, for the Milk is rich and abundant, ſo that rarely any Harm happens from this; whereas the bringing into the World with them an Abundance of Humours and a Groſſneſs of Habit, is commonly their Deſtruction.

Therefore it appears on all Hands, and from a Compariſon of all Things together, that it is greatly to the Advantage of the Farmer, that his Cows ſhould go the Year round with Milk, and conſequently that it becomes his Intereſt to watch and obſerve them the whole Time; for that a Cow that yields but moderately, and continues it without any Interruption, is better for him in every Reſpect than one that yields an Abundance at firſt, and grows dry afterwards. This is not the common Opinion, for that is on the contrary Side, but the Truth lies wholly here; and therefore the Experience is the more uſeful.

CHAP. VIII.

Of the Manner of milking.

THIS may ſeem a Conſideration too trivial to have a Place in ſuch a Work as ours, but we ſhall not therefore neglect it: nothing is trivial that may prove of Conſequence; and it is to this ſingle Vanity of over-looking Things of Importance, under the Name of frivolous and unworthy Conſideration, that the greateſt Part of the Writings on this Subject are wholly uſeleſs.

The Operation of milking indeed is very trivial and very eaſy; but as eaſy as it is 'tis not enough underſtood. It is entruſted to Perſons who have little Senſe or Conſideration, and who learn it they don't know how; nor does the Owner ever concern himſelf whether they do it well or ill.

There is a great deal of Difference between handling the Teats gently and roughly; and ſome Knowledge is required to tell how the Milk ſhall be got with moſt Eaſe to the Creature.

Milking, when carefully performed, is an Eaſe and Pleaſure to the Cow; but it may be ſo managed, and it too often is, that 'tis a Pain and Torment to her.

We have obſerved that there are Cows naturally ill-conditioned, but theſe are not common; the greater Part of the Accidents that happen in this Way, and are laid to the Fault of the Cow, are owing to the rough and ill Conduct of the Perſons employed to milk her.

The Farmer alſo is not unfrequently diſtreſſed by the Diſorders of the Cow's Teats, and the Hedgehog at this Time is blamed, as the Fairy uſed to be accuſed formerly of being the Occaſion of thoſe Diſorders; but in general, the Urchine is as innocent as the Spirit; and the Diſorders are owing to Hurts in the handling of the Teats.

Having thus repreſented to the Farmer the Miſchiefs that ariſe from an unſkilful Way of milking, and the Neceſſity of its being performed in a better Manner; we hope he will not accuſe us according to the vulgar Cuſtom, of deſcending too low in the taking it under Conſideration, nor neglect the practical Directions we ſhall give upon the Subject. His knowing what is proper to be done is the moſt important Conſideration of all, for he will be able to ſay what is right and what wrong; to inſtruct the ignorant, and to over-look the opinionated: now and then giving an Eye to the Matter himſelf, and giving his Inſtructions where they are wanted, and Reproofs, where they are deſerved, will ſet all right, and occaſion his Buſineſs to be conducted in this Point much more to his Satisfaction and Intereſt than he could otherwiſe expect.

When the Milker goes to her Work ſhe muſt take the neaſ Side of the Cow, and begin by gently handling and ſtroaking down the Teats; and from time to time ſhe muſt moiſten them with Milk, to make them ſupple and pliable; and by this Practice they will be brought to anſwer to her Touch much better, and will yield the Milk more readily and freely, and that without any Pain to the Creature; indeed on the contrary with Pleaſure.

There is palpably all this Difference in the Manner of milking. The Quantity in the Udder is a Burthen and great Weight to the Cow, and ſhe wiſhes earneſtly to be relieved from it; but if that be done with Harſhneſs, ſo as to occaſion more Pain for the Time than the Load of Milk, then ſhe will avoid it: on the other hand, if ſhe be milked kindly and gently, beginning as we have directed, not only the eaſing her of the Load is a Relief, but the very Manner of doing it is a Pleaſure. Every Mother who has given Suck knows there is a Pleaſure in performing that Office to the Infant, independent of any Thought of the Mind: this Pleaſure is in the Nipple itſelf, and this the whole Creation of Female Creatures that give Suck have; and it is the ſame in milking as in ſucking.

To this rude Method of handling the Teats is owing, as we have ſaid, a great deal of the ill Diſpoſition of ſome Cows; and to the kind and gentle Treatment others receive it is owing that they are kind and gentle themſelves. A Cow that is well fed will have her Udder full at certain Times, and when ſhe knows ſhe can be relieved from that Load without Pain, ſhe will come of herſelf to the Pail, and will ſtand with all poſſible Satisfaction.

We have ſaid in what Manner the Milkmaid is to begin her Work, and ſhall add how ſhe is to continue. She muſt not fix herſelf, nor ſet her Pail firm to the Ground, till ſhe has got the Cow to ſtand ſure and quiet: theſe Creatures are often very reſtleſs in the Beginning, but they will ſtand ſtill enough when the Milk has come for a little while freely. This muſt be watched, becauſe the Milk that is got will be otherwiſe in Danger. The Cow is a heavy Creature, and a little Kick of her Foot will bring the Pail down.

When ſhe is once ſettled, and the Milkmaid is ſeated, and all goes on for ſome Minutes right, there is leſs Danger, but ſtill the Woman muſt be always upon her Guard, a Cow may ſtart at any Time, and ſhe muſt have her Eye upon all her Motions, and her Hand upon the Pail, ready to remove it upon Occaſion, otherwiſe the overturning of a Pail is very eaſy, and the Milk may be all loſt in a Moment, that this careful Eye might have ſaved.

When the Cow is quiet and ſeems pleaſed with the milking, then let the Woman go on boldly; that which would have pained the Creature cruelly at firſt, will not hurt her at all now, that the Teats have been handled, moiſtened, and rendered ſupple; let her therefore now pull and ſtrain them freely, and draw as long as any Milk will come.

This laſt Article muſt be treated of more largely than in thoſe few Words. The worſt Fault a Milker can be guilty of is, the not doing it clean and thoroughly. Let the Farmer or his Wife frequently ſee to this: they ſhould give all their Milkers Orders to take Care, that not a Drop of Milk be left in the Udder when they leave off; and they ſhould ſee at Times, when they are at their Work, whether thoſe Directions are punctually followed. If there were nothing but the Loſs of ſo much Milk as is left in the Udder that is but half drawn, that would be ſome Conſideration, for in a Number of Cows it would amount to what was conſiderable, and this twice a Day would, in the Year's Courſe, make a great Diminution in the Profits of the Dairy: perhaps this alone would make the Difference of four or five Cows in a Year, and the Farmer knows the Value of their keeping well enough, to be ſenſible what a Fault that would be. But there is a much greater Conſideration than this, for there is nothing that tends to keep a Cow ſo full in Milk, as the conſtantly milking her quite clean; and on the other Hand, there is no Way ſo ſure to make her ſoon dry, as the milking in a careleſs Manner, and always leaving ſome behind in the Udder.

This depends upon the Courſe of Nature in furniſhing the Udder with Milk, as we have ſhewn. While it is drained Nature gives a continual and conſtant Supply, whether that draining be done by the Mouth of the Young or the Hand of the Milkmaid; but as ſoon as no more is drawn no more is provided. This is the Caſe at large when the Young dies, or the Creature is any way left untouched; and the ſame Thing holds good, in a proportioned Degree, when ſhe is careleſsly milked, and the Udder not well drained.

When that is perfectly emptied at Times, Nature goes on vigorouſly with a Supply; but when it is done but imperfectly ſhe performs her Work languidly, and there is not that free and full

Supply

Supply any longer. The Farmer knows the Importance of keeping his Cows deep in Milk, and a long Time in it; and it is fit he ſhould perfectly know, and thoroughly conſider how much that important Article depends upon the Milk-maid's doing her Duty.

Another Caution to be given to all Milkers is, that they make themſelves as familiar and friendly with the Cows as poſſible. By Gentleneſs and kind Treatment they will come to know them, and will go to the Pail like rational Creatures. While they are milking common Diſcretion will teach the Perſon not to do any thing to ſtartle or frighten them; and it is a good Caution alſo to let them go quietly and eaſily away. I have ſeen many drive their Cows away haſtily and roughly, as ſoon as they had done, as if they never were to have any thing to do with them again. All Creatures have Memory: the Cow does not forget this; and it is that makes her ſhy or troubleſome the next Time: let them always be treated tenderly, and let them go peaceably as they come: there is no other Way to have them come peaceably again.

CHAP. IX.

Of ordering the Milk in the Dairy.

THE Farmer has ſeen every Article neceſſary to be done in the obtaining his Milk from the Cow, let him now take Care of it when he has got it: he has taken the proper Meaſures for having the beſt Cows; for getting the moſt from them; for keeping them long to it; and for avoiding Miſchief in the drawing it; we will ſuppoſe it therefore in the Pails, and bringing Home; and that he is deſirous to make the Dairy fit to receive it in the beſt Manner.

The firſt Thing, and the moſt important of all in a Dairy, is Cleanlineſs. Not only all the Veſſels and Utenſils, but the very Floor, Walls, and Cieling; every thing that is in it, and every thing that is about it, muſt be thus managed with the utmoſt Nicety of Cleanneſs, or there will be continual Damage and Loſs.

The great Article in a Dairy is to keep all ſweet; and there is no Way to keep Things ſweet like keeping them perfectly clean: this Reaſon dictates, and this Experience confirms.

The Dread that ſhould always be uppermoſt in a Dairy is of Sowerneſs: and to keep Things from ſowering the Receipt is the ſame; that is, keep them clean.

Milk will at the beſt keep but a little while. All the Art and all the Care in the World cannot keep it long: it will become ſower, and there is the great Damage. When it has once got ſower it will ſpread the Miſchief, and this is what the Miſtreſs of the Dairy is to employ all her Care to prevent; and the far greateſt Part of that Care centers in the ſame Point Cleanlineſs.

The Foulneſs of a Dairy is uſually from corrupted Milk or Cream, and this muſt be cleaned away perfectly, for it will otherwiſe not only communicate itſelf to whatever is near it, but will infect the very Air of the Room, to the Prejudice of the whole Quantity of Milk that is brought into it, and of every thing that is going forwards. What the old Wives uſed to attribute to Witches and Fairies, was in reality the Effect of ſomething ſower left in the Dairy: this was the natural and real Cauſe, but the Effects of it are ſo great and ſo perplexing, to ſuch as do not know the Cauſe, that no Wonder they thought Witchcraft had a Hand in it.

Here then lies the firſt Article of Cleanlineſs, which is to take Care no ſpoiled Remains of a former Buſineſs hang about the Dairy, nothing ſower remain in any Crack or Crevice; for this End all the Pails, Pans, and Veſſels, muſt be daily perfectly cleaned; and for this Reaſon glazed Earthen Ware is preferable to any other Materials for them, becauſe nothing ſticks to it, there are no Crevices in it, and one may always ſee whether it be clean.

Thoſe who are at all acquainted with the Buſineſs of a Dairy, know how nice and tickliſh all the Works of it are; therefore let them take Care not to add to the Hazard or Perplexity by Foulneſs. We have mentioned the Remains of any thing ſower as the firſt Article, becauſe that is a Miſchief that ſpreads ſo quick and ſo far, but we are alſo to caution the Houſewife againſt Greaſe, Dirt, or Filth of any Kind whatſoever; for every thing that does not belong to the Work of the Dairy hinders it.

There is no Way to clean and ſweeten the Veſſels, but by ſcalding them with boiling Water, and then ſetting them out in the Air: the firſt cleanſes off all Filth that is viſible to the Eye, and the latter removes any Taint by purifying and evaporating any thing that remained about them. There is nothing equal to the Sun, Wind, and Air, for purifying Things after proper cleaning, and this Practice ſhould be uſed in the Dairy every Day, whether the Things appear dirty or no; there may be Filth about them that is not ſeen, and the leaſt of it will do Miſchief.

CHAP. X.

Of the Veſſels of the Dairy.

THE Uſe of the Dairy is to produce from the natural Milk, ſuch Products as the Farmer ſhall find turn beſt to his Account; and the ſeveral Veſſels employed in it all tend to that Purpoſe. Theſe we are to conſider in two Lights, with reſpect to their Form and their Materials.

As to their Form we are not ignorant of the many new Inventions that have been ſtarted for the facilitating the Operations of the Dairy; nor do we utterly adviſe the Farmer from regarding them; but this Caution we ſhall give him, that he do not rely too much upon the Words of their Inventors, or of thoſe who have ſo warmly recommended them. Theſe have been in general People of Ingenuity, but of no Experience. They have ſeen the Conveniences that might attend ſomething of the Nature of what they propoſed, but they have not perceived what might be the

In-

Inconveniences of their own particular Invehtions, therefore the Farmer, or practical Dairyman, is to try before he approves: he is obliged to those Gentlemen for the Hint, but he is to determine for himself, for he can do it much better than they, whether that Hint can be reduced to Practice.

Thus it is the reasonable Husbandman will consider all that is offered for the Improvement of his Profession, neither rejecting at Random, nor adopting without Proof. Many Things appear very feasible in the Closet, that are utterly impracticable in the Field: there is therefore no other Way of judging of them than by the Help of that Experience first, which their ingenious Inventors wanted; and afterwards, if this Experience joins in the Opinion, then to bring them to a Trial.

'Tis thus we advise the Farmer to consider the several new Improvements of a Dairy; and having given him this Hint, or if we may use the Expression, this Rule of Practice with Respect to the new, we shall proceed to inform him in the Management of the old and accustomed Methods: these are sure, and to confess a Truth disagreeable perhaps to the Inventors of new Schemes on this Head, I have never yet found upon Trial, that any others, with all their specious Promises, exceeded them.

As to the Materials of which the Vessels for the Dairy should be made, we have already declared for glazed Earthen Ware; but that not so absolutely as to reject those of all other Kinds.

People of Fortune who have amused themselves with the Pleasures of a Dairy in the Country, have covered their Walls with Dutch Tiles; and had their Vessels of China, and this is extreamly right. As to the Vessels, China are in this Respect as good for Use as glazed Earthen Ware, but not in the least better, for they are covered in the same Manner with a Glazing; and so a Vessel be glazed, and the Glazing whole and without Flaws, 'tis no Matter whether it were done in the EAST INDIES or at Home. There is a Difference in the Materials used in the Manufactures of EUROPE and the East on this Occasion, but it is not material in this Consideration. Our Glazing for these Vessels is made of Lead, and theirs is only a kind of Earth mixed up in Water, but the Effect is the same. Either is a glassy or shelly Substance which the Milk cannot penetrate, and therefore they equally answer the Purpose.

As to the covering the Walls with Tiles it is certainly right, as it answers two Purposes, both very essential to a Dairy, Cleanliness and Coolness. I have seen a Dairy in WILTSHIRE lined throughout with Lead, and it had also a very good Effect. The Expence of this last Method will appear considerable at first, but taking in the whole Account nothing is so cheap. It lasts from Generation to Generation without Repairs, and it has always a very considerable intrinsick Value: so much Lead is worth so much Money at any Time.

The usual Kinds of Vessels are three, Earthen Ware glazed, Wood naked, or Wood lined with Lead. As to the first we have spoken, the second is very good, but it has less natural Coolness, and is not so easily made perfectly clean as the Earthen Ware; the Lead has all the Advantage of Coolness, and may easily enough be kept clean.

The Difference is not very great, but the Reason will easily be seen in what we have here said, why we give the Preference to the Earthen Vessel.

Where the Dairy lies low, and is in itself very cool, Wooden Vessels do better than elsewhere; and where there is a very great Business carried on, there is Convenience in Wood lined with Lead, because Vessels may thus be made of such a Form and Bigness, as cannot be had from the Potteries. On all Occasions the Shape of the Vessels should be broad and shallow: this answers two Purposes; for it makes the Milk yield the largest Quantity of Cream, and it keeps it the longest from sowering. It is a Rule founded upon repeated Experiments, that a Quantity of Milk under the same Circumstances otherwise, will always sower the sooner, the deeper it lies together in the Vessel. Upon these Principles, founded on Experience, not on any fanciful Theory, stands the whole Matter of the preparing a Dairy for the Reception of the Milk.

CHAP. XI.

Of setting the Milk for Cream.

THE Dairy is now ready for the Milk, and that is coming Home in Pails upon the Shoulders of the Milkers, the Vessels in which it is to be set are placed ready to receive it; but there is one thing to be considered previously to its being put into them.

We have taken Care that there be no Dirt in the Dairy, let us take the same Precaution that none come into it from the Field. Too much Cleanliness can never be recommended to the Milkmaids, but let them take what Care they will, they can never keep their Pails perfectly free from Dirt, or some accidental Foulnesses: The Hairs from the Cow will fall into them, and other little Matters of the same Kind may also. Now all these, however they are blended among the Milk, would rise with the Cream, and so not only disgrace the Housewife, but disturb all the Operations that are to follow; for we have shewn that any the least Filth will perplex and teaze the whole Management afterwards.

To prevent Accidents of this Kind the Milk is to be strained; and this is to be done in a very easy and familiar Manner, by Means of what the Housewife calls her Soiling Dish, or as they commonly speak it the Syle Dish. This is a wooden Bowl, with its Bottom cut out, and the Opening covered with a Piece of fine clean Linnen Cloth.

This Bowl must be every Day scalded, and set out in the Air to sweeten like the rest, and Care must be taken that the Cloth be always perfectly clean. Through this Dish the Milk is to run into the several Vessels prepared to receive it, and then it will run perfectly clean and pure, for the hollow'd Bottom will stop the smallest

ſmalleſt Particle, and thus nothing but the Milk can get into the Veſſels.

Thus far then we will ſuppoſe our Houſewife has provided with perfect Care and Regularity, her Milk is perfectly pure, and is in the Veſſels perfectly clean: there is therefore no Danger of any Injury to it, and 'tis now to be left to Nature. The Dairy is cool, clean, and quiet, this is all that is needful, or can be done to promote the gathering of the Cream: properly ſpeaking nothing can be done to promote this, for it is a natural Procedure, and muſt go on in its own Way, all that can be done is to prevent Dirt, Heat, or Diſturbance; and this we have contrived already to do in the Structure of the Place.

The Milk, as we have ſhewn, is compoſed of different Parts: theſe are kept mixed while it is in the Body of the Animal, but they ſeparate one from another when they are out: this is that Separation which prepares for the Operations of the Dairy. The rich and fatty Part ſeparates from the poor and watery; that is, the Cream riſes to the Top, and leaves the thin and watery Part at Bottom. The broader and ſhallower the Veſſel is in which it is ſet, the more freely, eaſily, and readily this Separation is made; that is, the ſooner the Cream gets to the Top, and the greater Quantity there will be of it, theſe are the two great Points the Houſewife deſires; therefore ſhe will always uſe ſuch Veſſels.

CHAP. XII.

Of ſkimming the Cream.

WE are ſenſible how lightly many of theſe Things are in general looked upon, that here make the Subjects of ſo many diſtinct Chapters, but it is to that want of Conſideration of what are called Trifles, that half the Diſappointments and Loſſes in a Dairy happen. It may eaſily be ſaid that every Houſewife knows when her Cream is riſen, ſhe is to ſkim it off: that is true, we do not take up her Time in telling her that ſhe is to do it, but we are about to acquaint her how ſhe ſhall do it to the greateſt Advantage; and from what we have ſeen of Dairies in ſome Parts of this Kingdom, no Part of Information relating to the whole Farm is more neceſſary.

We have recommended Cleanlineſs in every Article relating to the Dairy, but here we are to repeat that Leſſon. There is nothing that requires more Nicety than the ſkimming off the Cream, nor any Article in which a little Dirt can do ſo much Damage.

We will ſuppoſe the Milk to have been brought in in the Morning, according to our Directions for the Summer milking, about Seven o'Clock; toward Afternoon let the Skimming Diſh be cleaned and got ready, and the Veſſels that are to receive the Cream. The Skimming Diſh ſhould be of a convenient Size for the Hand, not too deep, and thin at the Edges.

The Time that Milk ſhould ſtand is a Point in which few are agreed, and about which moſt err. I ſhall endeavour to ſet the Matter in as certain a Light as its Nature will bear: perfect Punctuality cannot be expected in any Rule on ſuch a Subject, but being in one Article eſtabliſhed, the Houſewife may vary according to her Diſcretion, as the Circumſtances vary: and it is better to have a Rule fixed for one Seaſon and Kind of Weather, than to have none fixed at all.

In Summer then I ſhall ſay ten Hours is in general enough for Milk to ſtand. Therefore this Milk having been brought in at Seven in the Morning, will be ready to ſkim at Five in the Afternoon; and this will be a very convenient Time to the Houſewife, becauſe what ſhe is now doing will prepare for the Evening Milking.

Many let their Milk ſtand longer than this in Summer, and conſequently vary according to the Circumſtances at other Times, but by what I have found from repeated Experience, there is no Rule ſo proper. 'Tis a very nice Point, and of very great Importance, either Way an Exceſs or Defect may be of great Damage; if the Milk be ſkimmed too ſoon the Houſewife has not her full Quantity; and if it ſtand too long the Butter made with it will ſuffer.

The firſt of theſe Points is plain to every one, but the latter is not ſufficiently known; or at leaſt not enough regarded. When Milk ſtands too long without ſkimming, the Cream gets a thick Head, and is untractable, and the Butter that is made of this is always bitter. I have known this in Inſtances out of Number, and when I have convinced ſome Houſewives that it was owing to this Fault of letting the Milk ſtand too long, they have tried every Method that could be thought of to prevent the Effect, but in vain: I have known them boil the Cream that was thus taken from Milk which had ſtood too long, in order to prevent this ill Taſte in the Butter, but to no Purpoſe; it has ſtill been as bitter as if nothing were done to prevent it.

What all the Pains and Care imaginable cannot remedy in this, as in many other Caſes, may eaſily be obviated, and that is the Leſſon which we give to the Houſewife. Prevent the Damage by ſkimming in Time.

We have given this Inſtance of the bad Effect of letting Milk ſtand too long, nor is it the only one by many, but it is ſo plain, and a thing ſo eaſily in every one's Power to try, that it is, we hope, ſufficient. Therefore, according to our Rule, let the Milk be all ſkimmed at Five o'Clock in the Afternoon, and let it be put into a proper Veſſel. The beſt Veſſel is an Earthen Pot well leaded, with a Cover. When it is put into this let it be ſet by in a cloſe cool Place.

The Cream is now taken off, put into the Pot, and ſet by, an Hour or more has been employed in this, and in cleaning the neceſſary Veſſels, and by that Time they are got in and ſet in order 'tis Seven o'Clock, and the Milkmaids come in loaded from the Evening's Milking. The Milk is to be ſtrained and managed exactly in the ſame Manner as the firſt, ſo there needs no particular Direction on that Head; and we ſhall therefore, to avoid Repetition, ſuppoſe the ſame Buſineſs gone through, and the Milk all ſet as the firſt.

The

The Houſewife may now be quiet for the Night, but let her take Care to be up early in the Morning. The next Article to Cleanlineſs is early riſing in this Buſineſs, and it is need ſhe be up, for the Milk ſhe has ſet over Night will be ready for ſkimming after ten Hours, or half an Hour more, that is, by Five, or ſoon after Five in the Morning. In general it will be beſt to allow half an Hour longer ſtanding during the Night than in the Day, becauſe the Night is cooler; and Experience ſhews that the Warmth of the Air has a great deal of Effect in the throwing up of Cream.

In this Manner the Cream will be taken off from the Evening's Milk; and all got ready for the Reception of that of the Morning, by that Time the Milkmaids come Home with it; and thus the whole Round of that important Article, the obtaining, ſetting, and ſkimming the Milk, will be managed without the leaſt Trouble or Perplexity, and every thing go on in a quiet and regular Order.

CHAP. XIII.

Of the Managment of the Cream.

IN the Cloſe of our laſt Chapter we left our Houſewife with her Pots of Cream, and her Dairy Work going on with due Regularity, we muſt proceed to adviſe her how to manage the Produce of her Pans in the beſt and moſt ſatisfactory Manner.

In this Article there is Need of the greateſt Caution, and that for the plaineſt Reaſon in the World, which is, that Convenience would naturally preſcribe the keeping it longer than it is found in Effect ſafe or proper to do.

The Weather makes a great Variation in this Article, and we are to obſerve alſo, that there are artificial Ways of aſſiſting Nature in preſerving it. However, as pure ſweet Cream, in its natural Condition, is vaſtly preferable to the beſt that is preſerved in whatever Manner by Art, we ſhall firſt give the Houſewife her Leſſon how long ſhe ſhould, and how long ſhe may keep it naturally; and afterwards inform her what may be done in the keeping it longer by Art and Management.

The fineſt and moſt excellent Butter is that which is made from Cream that has not ſtood above ten Hours in the Summer; on the other hand, in Winter it may be kept much longer without Damage. When we name the Time of ten Hours, it is by Way of limiting the Space in which it is quite perfect; for Butter that is made from Cream ten Hours old, or from ſuch as is juſt ſkimmed is altogether the ſame. After this, in Summer it begins to find ſome Change, but it is little for the two ſucceeding Days, only in general the newer the better.

The Seaſon makes ſo great a Variation in this Matter, that Cream may be kept very well twice as long in Winter as in Summer.

In Summer it may be kept without any material Diſadvantage two Days and a half; and in Winter it may be kept in the ſame Condition five Days.

The Houſewife who intends to have Credit in her Butter, if ſhe takes Care not to let the Milk ſtand too long before it is ſkimmed, may very well keep it thus long without any particular Management; but if ſhe intends to have more of it together than can be got from her Stock of Cows in that Time, or to churn but at certain Times, which require the Cream to be kept longer, then ſhe muſt uſe ſome Art to preſerve it.

In this Place howeyer it may be neceſſary to obſerve, that in making Butter for Sale in large Quantities, there is no Objection to the Cream being kept longer. In this Caſe it turns ſour; but the Butter is not the worſe for Market, unleſs it have been over-heated or otherwiſe ill-managed in the Churn. The fine Butter for preſent Uſe ſhould always be made of perfectly freſh Cream; but for this marketable Commodity the other is rather preferable; for Experience ſhews that Butter made otherwiſe under the ſame Advantages, keeps better when the Cream has ſtood to be ſour, than when it was ſo perfectly freſh, unleſs it turn bitter: this, in Butter made from Cream that has been kept till ſour, is always a Mark, and is always the firſt Mark of its tending to Decay; wherefore in that Caſe, the ſooner it is uſed the better.

The fine Flavour depends on the Freſhneſs of the Cream, but otherwiſe the Butter is not the worſe for ſome keeping.

Theſe are Particulars we ſhall conſider more particularly in a ſucceeding Chapter, treating of Butter, but thus much it was needful to ſay here, that the Houſewife may exactly know not only how long her Cream is to be kept, but what are the Diſadvantages of keeping it longer.

Having explained this Matter ſo far, we ſhall proceed to tell her what is to be done, when ſhe is deſirous of keeping it longer than it is poſſible for her to expect it naturally to laſt good.

The Days of Market often regulate the Days of churning: there is ſome Convenience in doing a good deal of Buſineſs in that Reſpect at once, and when there is but one Market near, and that but one Day in the Week, which in the Country in many Places is no uncommon Thing, it will be a great Convenience to the Houſewife if ſhe can contrive to churn but once in the Week, and to prepare all together for the Market. We ſhall ſuppoſe this the Caſe, as it is a very common one, and lay down a Method by which ſhe may in Summer be able to keep her Cream the whole Week without its growing ſour, though in the common Courſe of Things it would be ſo in three Days.

This is to be contrived thus. We will ſuppoſe the Market Day THURSDAY. Then FRIDAY may be called with her the Beginning of a new Week; but as her Cream will have been gathering ſooner, we ſhall trace it from that Time.

In order to prepare for the Market on THURSDAY, ſhe has been churning on WEDNESDAY, and ſhe will have taken into her Churn the Cream of WEDNESDAY Morning, that is, what was ſkimmed from the Milking of TUESDAY Evening, the laſt that can go into the Account of that Week.

The WEDNESDAY Morning's Milking is ſet

for Cream, and that is taken off at Evening but ſet by, this therefore is the firſt Parcel for the ſucceeding Week: to this is to be added all that follows till the WEDNESDAY Morning again, which ſhe is to preſerve for the Churn on that Day. Let every ſucceeding ſkimming be mixed with this firſt, and on SATURDAY Morning let her ſet all the Cream ſhe has got over the Fire, and let it juſt once boil: this done let her put it back into a clean Pan, and then add to it all that is taken off the Milk during the following Part of the Week, but let her every Day change the Veſſel in which it is kept, pouring it daily into a freſh one well cleaned and aired.

It is very ſtrange to ſee the Effect of this, the boiled Cream not only keeps good itſelf, but by the Practice of every Day putting into a freſh and perfectly clean Veſſel, it preſerves all the reſt from being ſour. This has been frequently tried in the Neighbourhood where I now live, and when it has been done with due Care has always ſucceeded.

We have now conducted the Houſewife from the milking of her Cow to the preſerving of her Cream, as long as her Convenience requires, and as it is then to be made into Butter, that comes next under Conſideration.

CHAP. XIV.

Of Butter.

WE have obſerved that Butter is the oily or fatty Part of the Milk, which firſt ſeparates of itſelf in Form of Cream, and after that needs but little Trouble, at leaſt but little Art to bring it into the Condition of an elegant ſolid, yet ſoft Subſtance, pleaſant to the Taſte, and fitted for many Purpoſes.

When we conſider Butter in this Light, of a Thing ſo very deſirable, and ſo very eaſily obtained, it appears wonderful that the Knowledge of it came ſo late into the World; but 'tis certain that there were very many Ages in which it was not known, and many Countries in which it was not uſed in Food long after the reſt of the World were perfectly acquainted with it.

The Greeks, Poets, and Philoſophers frequently mention Cheeſe, and yet the Name of Butter is not found in their Writings. It is certain that the only Uſe they made of Milk in thoſe Times was to drink it alone, eat it with Mixtures, or make it into Cheeſe; for not only they are ſilent on the making Butter, but it is evident from the whole Tenour of their Writings, there was no ſuch Thing in uſe among them.

ARISTOTLE has written largely of Milk and its Products, but among theſe there is not a Word of Butter; he only treats of Cheeſe of ſeveral Kinds, and the Whey, of which there were alſo ſeveral Sorts, according to the Manner of making the Cheeſe.

The ROMANS made Butter; but what is yet more ſtrange than the former, they, though they had it, never conſidered it as an Article of Food; they uſed it as a Medicine; and we read their Sentiments concerning it in PLINY, where we find they were well acquainted with its Uſe in other Countries. It is very well known that the People of the EAST INDIES knew nothing of Butter, till the DUTCH took it over to them.

We ſee in this an Inſtance of a very great Truth, which is, that the moſt familiar Things may be a long Time over-looked, and that what every Man wonders he did not find out himſelf, as ſoon as the Secret is diſcloſed to him, Millions beſide himſelf may have left all their Days undiſcovered.

Butter is made from Cream by the Aſſiſtance only of Motion: this may be given it any Way, and provided it be in a proper Degree, the Effect will be produced. This Motion in the common Way of performing it is called churning; and the Uncertainty of that has led the Ingenious to contrive many Methods of ſupplying the Place of beating by the repeated Labour of the Hand, ſome of theſe are much worſe than the old plain Way, and there are others that really deſerve the Name of Improvements.

There are certain Particularities relating to Butter, much better known than underſtood: it will be very well worth while for thoſe who have the Convenience of being upon the Spot, to endeavour to diſcover the Reaſons. In the mean Time all we can do is to mention the Facts.

SUFFOLK Butter is famous for keeping, which is a Quality of ſo much Importance, that every Method is to be taken in Hope of finding the Cauſe of it. Indeed there are Methods of makeing any Butter keep longer than may at firſt be imagined practicable; if good Butter be made up in Lumps of forty Pounds Weight, and a little more Salt be put in than is uſually allowed, and they be afterwards put into a large Bin of Flour, they will keep the Year round without Damage.

Toward the End of Autumn Butter is apt to taſte bitter. This is one of thoſe Things better known than its Cauſe; it has been ſaid that the Reaſon is, that Graſs beginning to grow bare at that Time, the Cows eat the Leaves that fall from the Trees; but however true it may be that Cows will feed in this Manner, it is not true that this is the Cauſe of the Butter's being bitter; becauſe in the Fen Countries, where there are no Trees, and where Ditches ſerve inſtead of Hedges for incloſing, the ſame Thing is apt to happen at the ſame Seaſon, as in Places where there is ever ſo great Plenty of Wood.

Though we cannot abſolutely aſſign the Cauſe of this, we can tell the Houſewife how to prevent the Damage, which is enough for Uſe if not not for Curioſity. There needs no more to this than to ſkim the Cream after a ſhorter Time ſtanding. We have obſerved before, that when Milk ſtands too long the Cream hardens on the Top of it, and the Butter made from ſuch Cream is bitter; this ſhews that too long ſtanding alone may be a Cauſe of Bitterneſs in the Butter, and for that Reaſon, where there is Danger of the ſame Accident from any other Cauſe, one would take Care to prevent this from joining to make it worſe: on this Principle has been founded the Practice of ſkimming Milk earlier at that Seaſon of the Year; and the Conſequence has ſhewn that this alone will prevent the Bitterneſs

of the Butter, whatever elſe was the Cauſe that would have made it ſo.

In Devonshire, and ſome other Places, they make a particular Kind of Butter, which from the Manner of ordering the Cream, is called ſcalded Butter. The Advantage of this is not only its being particularly well taſted, but that it will keep a Month without Damage. The Way they raiſe their Cream for this Purpoſe is the ſame the Chemiſts uſe when they have a Mind to give any thing a gentle Heat, without burning it to the Veſſels, and which they call a Balneum Mariæ, or Water Heat.

It is done in the ſcalding the Devonshire Cream thus:

They ſtrain the Milk into Veſſels as is uſual, and ſet it by for the Cream to riſe. Ten Hours afterwards, when the Cream is riſen in the common Way, they ſet the Veſſel with the Cream, Milk and all, over ſome Water in another Veſſel, ſo that the Water reaches half Way up that wherein the Cream is: this done they ſet the Veſſel of Water over a Stove, and gently heat it till the Cream is thoroughly and perfectly riſen, and the Milk underneath is quite thin and blue. The gradual and ſoft Heat does this, throwing up the whole Cream perfectly, and at the ſame Time doing it a great deal of Service, for the Article of keeping by the Heat.

When it is in this Condition the Cream is ſkimmed off with a ſkimming Diſh full of Holes, and the blue Milk is let to run perfectly away from it.

In this Condition it is a Kind of clouted Cream, the Fire ſo gently conveyed to it has done it great Service; and it may be kept with proper Care ſeveral Days, ſo that enough of it may eaſily be got together for churning. All that is needful for preſerving it during this Time, is ſhifting it once in four and twenty Hours into a freſh and perfectly clean Veſſel. This is one of theſe Inſtances, wherein we ſee the Value and Advantage of Cleanlineſs, but it is not particular, its good Effects are univerſal. As to the churning of this Cream no Difference is to be uſed from the common Method.

CHAP. XV.

Of churning.

THE Cream is now ready for the Churn, whether freſh or kept according to the Rules we have given for that Purpoſe, and we ſuppoſe the Time arrived when Convenience calls for the making of the Butter. We ſhall conſider firſt the common Way of making it with the old faſhioned and long uſed Churn. This is a Veſſel of Wood, tall and deep, wideſt at the Bottom and narrower to the Top, where it has a Cover that falls in cloſe, and has a Hole in its Middle. Through this Hole is let the Handle of the Inſtrument, wherewith the Cream is to be beat; this conſiſts only of that Handle, and a round Board, like a broad thick Trencher at the Bottom, in Size ſuited to the Middle of the Churn. When this is put in, the Handle is let through the Hole of the Cover, and that is then put on and faſtened down. This is the whole Contrivance of this familiar and uſeful Inſtrument; all that is required for making of Butter is well beating of the Cream. And it is very well done by this Inſtrument, for the Cream being in the Churn, the working of the Handle up and down in the Hole of the Lid naturally agitates and beats the Cream, and the faſtening of the Cover prevents its riſing out.

This Churn, which is the good Houſewife's old Implement, is to be made clean with all poſſible Care, by thoroughly waſhing and ſcalding, and then expoſing it to the Air to ſweeten and purify. When every Part belonging to it is thus perfectly cleaned, it is to be brought into a proper Part of the Dairy, and this differs according to the Seaſon, for which Reaſon there can be no particular fixed Place for its ſtanding.

All Niceties are to be obſerved in churning, for it is well known to the Houſewife, to be a very precarious Article; and often when all the Care poſſible is uſed, the Work goes on very vexatiouſly, and the Butter will not, as they expreſs it, of a long Time come.

A moderate Temperature of the Air is the moſt favourable for the working of Butter; wherefore, according to the Seaſon of the Year, this muſt be favoured by the Place of the Churn. In every Dairy there are ſome Places warmer and ſome cooler than others. Now in Winter the Churn muſt be ſet in the warmeſt Place; and in Summer on the contrary it muſt ſtand in the cooleſt, for the Succeſs of the Work.

In the ſame Manner the Time of churning muſt be varied according to the Weather. In the Heat of Summer, the Weather being naturally too hot for the making of Butter, no Hours are proper but either very early in the Morning, or very late in the Evening, becauſe then only the Air is in that temperate Way, ſo eſſential to this Buſineſs; on the other Hand, as the Air is too chill and cold in Winter, the ſame Caution muſt be uſed in an oppoſite Manner of Choice, that is, the Middle of the Day, and no other Time is to be taken; becauſe it is at the Noon Time alone, in theſe Seaſons, the Air is any thing like temperate.

The Hour and the Place of the Churn being fixed, the Houſewife has nothing to do but to go to work. She is firſt to ſtretch a coarſe, ſtrong, and very clean Cloth acroſs the Top of her Churn, and into this to pour the Cream. Cleanlineſs we have all along preſcribed as the firſt Virtue of the Dairy, but here it is ſo very eſſential, that the Admixture of the leaſt Particle of Dirt might prevent the whole Buſineſs, and all the Labour be done in vain. When the Cream is ſtrained and preſſed through this Cloth, the Churn is to be covered in with the whole Preparation, and the Maid is to go to work.

There is great Uncertainty as to the Time of the Butter coming, but this depends more upon the Manner of beating, than any of thoſe fantaſtical Cauſes to which it has been aſſigned. Thus a heavy, tedious, dull Manner of beating gives the Cream Time to gather again between Stroke and Stroke, when it was about to break; and on the contrary, the ſwifteſt Work does the moſt Buſi-

neſs. Therefore let the Miſtreſs firſt examine the Manner of working of thoſe who complain, ſhe will commonly find Lazineſs is the Devil in the Churn, that ſets his Spell upon the Butter. Let her overſee the Work at firſt, and ſee it is done briſkly, with ſwift, ſharp Strokes, and tell the People, for their own Sakes, to continue it in the ſame Manner.

She will know by the Sound of the Strokes how the Work goes on. At firſt the Noiſe is deep, ſound, and heavy; but after a Time, the ſooner the ſharper the Strokes, it will begin to be higher and ſharper. This is a Proof the Cream begins to ſeparate from the thinner Part that yet remained with it, or as they commonly expreſs it, that the Butter comes: the Work is now to be continued with the ſame Spirit and Earneſtneſs, and the Effect will ſoon follow. The Staff will be perceived to work lighter; and ſoon after this, upon opening the Churn, and examining the Top of the Lid on the Inſide, there will be found Drops ſticking to it that look yellow. The Butter is now coming, and there will ſoon be an End of the Labour, for theſe Drops are abſolute Butter, and when the Change is thus perfect in one Part, it will not be long before it is ſo throughout; after a few Strokes more let the Churn be again opened, and there will be found Butter on the Sides as well as Lid, and every where, ſo far as the Splaſhing can reach.

The Butter is now made, and is only to be got together. For this Purpoſe the Lid and Inſide of the Churn muſt be ſcraped clean, and the Butter, which is got off from them, muſt be put down among the reſt into the Body of the Churn; then all is to be covered up again, and the Work continued, but not with hard downright Blows, but with a Kind of ſlight rounding Strokes; for all that is to be done now is to get the Butter together into a Lump in the Churn, that none of it may remain in ſeparate Pieces. When this is done the Butter is finiſhed, and is to be taken out of the Churn.

This is the general Method; and theſe which we have named are the Cautions always to be obſerved: but having thus far explained theſe, we ſhall now enter upon thoſe Particulars which promote or retard the Formation of the Butter in the Churn, that the Houſewife being aware of what will prevent her Succeſs, may guard againſt it; and knowing what will forward it, may purſue it.

The Temper of the Air we have named already, as a very great Article, and are to repeat the ſame here on another Occaſion; for it not only may retard the coming of the Butter, but may ſpoil it when it is made.

Over hot Weather not only makes churning difficult, but the Butter, when it is made, is ſo far influenced by the Weather, unleſs properly guarded againſt, that it is whitiſh, brittle, and bitter; we have ſhewn how to avoid theſe Accidents, by taking an early or late Hour and a cool Place. The early Hour is better than the late, for the Air is cooler in the Morning before the Sun riſes, than it can be in the Evening, after it is ſet, becauſe in one Caſe it has been heated all the Day, and in the other it has been all the Night cooling; as to the Place, the hotter the Seaſon the cooler that muſt be. I have ſeen very fine Butter made at Noonday in August, in an Ice-houſe. This may ſerve as a Proof how poſſible it is to countervail any Heat of the Air, by the Coldneſs of the Place. Ice-houſes are not in the Farmer's Power, but neither need he uſe the Middle of the Day for churning, a cool Cellar, or the deepeſt and remoteſt Place in his Dairy, two Hours before Sunriſe in a Morning, will be equal in Coldneſs to the Ice-houſe at the Middle of the Day.

In the coldeſt Time of Winter it is often very difficult to make the Butter come at all; and I have ſeen ſo much of this, that I think the Experiment I ſaw tried in the Ice-houſe could not have ſucceeded as it did, were it not that the Cream when carried in had a great deal of Heat in it from the common Temper of the Air, and the Butter came before the extream Cold of the Place had any great Effect upon it.

Having thus laid down the general Principles, and explained the Reaſons of the Difficulties which often perplex the Houſewife in her churning, we ſhall in the next Chapter lay down a few plain, eaſy, and practical Rules for her Aſſiſtance.

CHAP. XVI.

Particular Rules relating to churning.

IN Summer, as the Heat of the Air is the Occaſion of the Difficulty in bringing the Butter, the Houſewife muſt take all poſſible Means to prevent adding to the natural Heat of her Cream, and to cool it gradually.

We have adviſed very briſk working of the Staff in general, but here muſt be a Kind of Exception, for too much Motion will occaſion Heat; and therefore in extream ſultry Times it will be better to manage the Blows accordingly, making every Blow ſmart and ſure, but not repeating them ſo quick upon one another.

There is ſome Myſtery and Art in churning at any Time, but it is at this that the main Difficulty occurs; and if it be not managed according to theſe Directions, there will be a great deal of Perplexity and Plague.

In the next Place, let the Houſewife take Care that ſhe does not add to the Heat occaſioned by the Weather, by any Heat in the Churn itſelf; and farther let her abate the Heat when it is naturally ſo much that nothing can be done by cooling it.

With Reſpect to the firſt Article, as her Churn is to be ſcalded in order to make it perfectly clean and ſweet for the Uſe, let her take Care that it be thoroughly cooled, before ſhe puts her Cream into it. Scalding Water gives a great deal of Heat, and Wood keeps it a long Time: therefore let the ſcalding of the Churn be the firſt Thing done in the Preparation for the Work, and let the Churn be thoroughly examined by the Hand half an Hour at leaſt before it is uſed, that it may be cool. Wood will retain Heat when the Hand does not feel it, but half an Hour's cooling, after no more is perceived, will

ſet it right. To add to this in very hot Weather it will be well to wet the Outſide of the Churn with Pump Water freſh pumped, a little before the putting in the Cream, but the Inſide muſt not be wetted ſo near the Time.

Under theſe Cautions, and uſing the proper Hours, there is Reaſon to hope the Butter may come without much Difficulty; but if, after a moderate Time, there be no Appearance of it, as nothing can be reaſonably ſuppoſed to be the Cauſe but Heat, let a Waſhing Tub be a third Part filled with freſh pumped Water, and brought to the Place where the Maid is churning; let the Churn be placed into this, and if the Water do not reach as high up the Outſide of it as the Cream riſes within, then let more be added till it does: let the Work be now carefully continued, and commonly, as ſoon as the Effect of the Water is felt through the Wood, the Butter will begin to come. It is not only that the Cream is thus brought to that Condition of Warmth, in which the Butter comes beſt, but the ſudden Change is of great Aſſiſtance: the ſame Effect that the cold Air of the Ice-houſe in the before-mentioned Experiment had upon the Cream, the ſudden Chillneſs of the Water ſhews in this Caſe; and doubtleſs, as a conſiderable Change is to be made in the Thing itſelf, for the Difference is really great between Butter and Cream, this quick Shock, better than any other Way, brings it about.

Theſe then are the little Particulars by which the Houſewife will be able to aſſiſt herſelf, in Caſes when the too great Heat of the Weather prevents her Succeſs; on the contrary, when her Difficulties are owing to too cold an Air, ſhe muſt, in the ſame Manner, aſſiſt Nature by giving a little Warmth.

We have adviſed her, in the other Caſe, to be very careful the Churn be cool from the ſcalding, but in this ſhe will do well to examine the Veſſel how it cools by Degrees, and to ſtrain in her Cream while there is yet ſome Warmth remains in the Churn, from the Water that cleaned it. This will give a little Help to the Cream; and the Maid muſt be ordered to work it more briſkly than ordinary; indeed the Coldneſs of the Weather uſually puts her in Mind of this, and the leſs Admonition is needful.

If with this Aſſiſtance the Butter do not come, let the Churn be taken into the Kitchen, and placed not within the Reach of the Fire directly, but in the Air of it, this will by Degrees bring the Cream to the due Temper. Then the Work of churning is to be continued briſkly, and it will not be long before there come good Butter.

There is generally more Trouble in getting Butter in very cold Weather, than at any other Time, but by theſe little Aſſiſtances it will be greatly alleviated; and there is nothing in all this that will be at all prejudicial to the Taſte or Colour.

CHAP. XVII.

Of the weſhing and making up of Butter.

THE Butter being now formed in the Churn, and by the laſt Strokes worked together into one large Lump, is to be taken out and finiſhed by a gentler Operation; the Strokes of the Churn would be now too harſh, it muſt be moulded in the Hands into a better Conſiſtence.

It is to be underſtood that Butter, when thus made in the Churn, is far from its Perfection. It is ſeparated from the watery Part in ſome Degree, but not entirely. The whole Operation depends upon this, that as in Milk there was a richer Part and a poorer, which being ſeparated by ſtanding, the richer Part ſwims at the Top, and is Cream; ſo in the Cream itſelf there are two ſeparate Subſtances, an oily, which is properly the Butter, and a watery, which is the Buttermilk. The ſeparating of theſe is what we call making of Butter.

This Separation is performed by agitating of Cream in a due Degree of Heat, and this being done perfectly the Butter is perfectly made. Now the Churn does this but imperfectly, being a clumſy and unweildy Inſtrument; but it makes a good Beginning, and the Hand is afterwards very well able to finiſh it.

This finiſhing conſiſts in two Articles, the perfectly ſeparating the Buttermilk, or thin Part, and the cleanſing the Butter from any accidental Foulneſſes that may have got into it, for this is always poſſible; and it is to be done in this Manner.

The Lump of Butter in the Churn is to be taken up with both Hands, and removed out of the Liquor. In this there comes a Conſideration, which is only to be determined by the Time the Butter is intended to be kept: if that be ſhort, that is, if it be made for immediate Uſe it is to be thrown into Water immediately, on taking it out of the Churn, if otherwiſe not.

Therefore whichever be the Caſe, let a very clean Pan of Earthen Ware glazed, be ſet ready by the Churn, and if the Butter be deſigned for Uſe immediately, let this be half full of clean freſh Water; if not let it be empty.

The Lump of Butter being lifted out of the Churn muſt be put into this Pan, and there worked thoroughly to and fro in the Water, or without, labouring it with both Hands, and moving it frequently about; by this Means the Buttermilk that remained in it after the churning will be thoroughly waſhed out, and the Butter will be pure and of a firm and good Conſiſtence: the well working, turning, and toſſing the Lump at this Time of the Operation is a very material Article, for to that alone the Butter owes its Purity, its good Conſiſtence, and in a great Meaſure its Colour, at many Times of the Year. I have ſeen Butter that looked white and chalkey, on taking out of the Churn get a very good pale Straw Colour, in the frequent and repeated working in the Hands among Water.

The

The Buttermilk being thus perfectly separated, one of the two Points intended by the working in the finishing of it up, is obtained; the other is the perfectly cleaning of it.

So much Care as we have advised, one would think, would keep out Dirt from the Butter, but it does not always happen; for a Rag of the straining Cloth, a Hair, or some other Impurity, may escape the Observation; and any thing, the least imaginable in this Kind, may damage the Butter in the Respect of Sale, and will always be a Blemish in the good Housewife's Character.

The working the Lump in the Hands may discover some Foulness of this Kind, which must be picked out as soon as seen; but lest any should have escaped the Eye, the whole must now be taken out of the Water, and cut cross and cross many Times with a Knife, till every Part of it have had the Knife in it, this will find out any little Thread or Hair, and thus it is to be made entirely clean.

The last Thing to be done is the salting. We are not here speaking of the salting that is to prepare Butter for long keeping, but just of that which is done to give it a Relish. Butter is very insipid when it is made up entirely without Salt, so that the freshest should always have some. It is to be worked into it in this Manner. The Butter that has been cut and cleaned is to be spread out thin with the Hand, in the Bottom of a broad shallow Dish; and then a very little Salt is to be sprinkled carefully over it, the Design being to mix it as equally as possible in the whole Quantity; it is then to be worked up well in the Hands, and is done: it may be wrought up into Rolls, Lumps, or Dishes, or formed in any Shape most saleable at Market, or most convenient in the Family. Having thus gone thro' the whole Work of making Butter, and makeing it up fresh, we shall proceed to the salting of it, that being a very essential Part in the Farmer's Traffick in some Places. But here, as we have named only the plain good old Family Way of churning, it may not be amiss to observe that there are others which have their Use.

The Sweep is a Kind of Churn which works in the Manner of a Pump, and is used with a great deal of Ease and Advantage in many Places: in other Parts of England they prefer the Barrel Churn, and it also answers very well; these Instruments are to be had at the Turners, therefore I shall say no more of them here, as I shall not take upon me to recommend them, though I allow they are good in their Kinds; the other always, so far as I have seen, very well answering its Purpose.

The greatest Preference that is made for using these, is the Quantity they can manage, and the Expedition of the Work; but I have seen twenty Gallons of Cream wrought at once in a common Churn, big enough to hold thirty; and this Quantity brought to Butter in about an Hour. When the Quantity is so large a Woman alone is not able to manage it, but a Man and Maid do it perfectly well.

In hot Weather Butter, though very well made, will sometimes continue too soft; and this will be a great Disadvantage in Respect of the Carriage to Market, and sometimes hurts the Sale. In this Case, as the Cause is known, the Remedy is easy. Too much Heat being the Occasion, a little additional Cold will set all to rights. This may be done with great Ease by the Help of a Well, which is a Convenience few Farms want. Let the Butter, when it is thoroughly made, and properly salted, be rolled into Lump Pounds, or half Pounds, according to the Demand there is expected for those several Sizes, and put carefully into a Basket: let a long Rope be fastened to the Handle of this Basket, and let it be let down into the Well till it come within two Foot of the Water. In this Way let it hang all Night, taking Care no Accident happen to it by Thieves or Carelessness of Servants, and in the Morning let it be drawn up and sent to Market. The cold Air that lies just above the Water in the Well, will have the same Effect as the natural Cold of Winter, and it will be as hard as Butter commonly is in November.

With Respect to the salting of fresh Butter, the particular Fancy, and Taste, and Custom of the Country, are to be so far considered, that it is very difficult to establish any general Rule; but in a moderate Way we may say, that a Pint of Salt will serve for twenty Pounds of Butter; some go as far as a Pint and half for that Quantity; but 'tis too much, for only the Flavour of the Salt is wanted, to take off the Insipidity of the Butter: therefore the least that will do is best; but those who go much under a Pint to twenty Pounds do not answer their Purpose, for the Salt is not so much as tasted when so little.

CHAP. XVIII.

Of the making of Butter from new Milk.

AMONG the Improvements that have been made in Husbandry of late Ages, this may be very justly reckoned one, for in large Concerns it shortens the Trouble of a Dairy very much. As we have given the Rationale of Butter making in the preceding Chapter, there will not appear any thing strange or wonderful in the Attempt, or in the Success of making Butter without the Trouble of first setting the Milk for Cream.

It has been seen that when Milk stands an oily Part separates, mixed with some Water, this is Cream, which consists of Butter the oily Part, and Buttermilk the watery. This is afterwards beat, that by Means of the Motion the remaining watery Part may be separated from the pure and oily.

Now it is plain that this oily Part, which is wanted for Butter, is originally in the Milk; and there is no Reason to wonder that beating, which in the common Way of working, drives out the watery Part, and separates the oily from the Cream, may in a greater Degree, separate this oily Part at once from the Milk.

This is the Principle upon which they proceeded, who first set up the Scheme of new Milk Butter, and it answered accordingly.

It is for this Use that Machines, and other Contrivances, are to be called in to the Assistance of the Farmer, the Quantity of Milk not reduced

duced to Cream being too great for the good old Implement the Churn; and the Labour required for ſeparating this oily or buttery Part from it, is ſo much greater than is needful for Cream, that no human Creature could be well expected to go through it. Therefore it has been properly contrived for this Purpoſe, that the Veſſels ſhall be very large, and eaſily put into a violent Motion, and that the Work ſhall be performed by a Horſe.

In ſome Places they contrive to uſe an Implement not unlike a common Churn for this Work, but it does not do near ſo well as thoſe Barrels that run round, with Stops in them for that Purpoſe.

The Farmer who has a Mind to fall into this Way, will eaſily get the Machine, the Structure of it being ſufficiently underſtood among the Mechanicks in moſt Parts of ENGLAND; but he may, by freſh Contrivances, ſave himſelf a great deal of Labour and Trouble: he may contrive his milking Place in ſuch a Manner, that the Milk may come directly from the Cow, through a Pipe, into the Veſſel; which, when the milking is over may be ſet in Motion, and at once make the Butter.

As we have named the Benefit of this Method, which is for the managing a great Quantity of Milk with little Trouble; it will be proper we fairly ſet before the Farmer alſo its Inconveniences. The principal of theſe is, that the Butter made this Way, though very good for preſent Uſe, is not found to keep ſo well as that made in the common Method.

The Buttermilk that is made this Way ſupplies a tolerable Kind of Cheeſe with little Trouble: they let it out into other Veſſels, and then add Runnet, and it comes to a Curd very readily.

Having thus gone through the Articles that naturally fell in the Way, before we come to the ſalting of Butter, we ſhall proceed to treat of that important Article in a plain and practical Manner.

CHAP. XIX.

Of ſalting of Butter.

IT is often neceſſary, and always profitable to ſalt Butter at certain Seaſons; but there are Times of the Year more proper than others. In general, the Butter of the early Part of Summer is not ſo proper for ſalting; and that of no Time is ſo good as what is made from the Middle of AUGUST to the latter End of OCTOBER.

The firſt Difference that is to be obſerved in the making, is when it is taken out of the Churn. We have ordered freſh Butter, that is, ſuch as is intended to be kept freſh, to be put into a Pan of Water, and there worked with the Hands to get out the Buttermilk, but in the Butter intended for ſalting no Water muſt be uſed to this Purpoſe. 'Tis to be put out of the Churn into an empty Pan, and there worked between the Hands, to ſqueeze out the Remainder of the watery Part.

This done the Butter is to be mixed with Salt, which is to be worked in with the Hands, the more the better, the Way is to ſpread out the Butter as in mixing that ſmall Quantity of Salt with ſuch as is intended for immediate Uſe; but inſtead of that ſmall Portion, as much as can be got in is to be added here, and when the whole is well mixed, the Butter thus prepared is to be put up in Pots or Barrels: for large Quantities Barrels are needful, but for leſſer Quantities Pots are more proper; but they muſt be well glazed, otherwiſe the Brine will eat into them. In Pots it is proper to lay in a thin Bed of Salt before the Butter is put in, and when it is put up then to lay another Bed of Salt over the Top of it.

In many Places where they barrel up large Quantities, they alſo pierce Holes through with a Stick, quite from the Top to the Bottom of the Barrel, and making a very ſtrong Brine, they pour in a Quantity of it over the Butter, and let it run down all theſe Holes, which is of great Service in preſerving the whole.

Some, inſtead of a Bed of Salt upon the Butter when they have potted it, pour over it a Quantity of ſtrong Brine, and this is no bad Method.

As for the keeping, which is the great Purpoſe for which Salt Butter is deſigned, though it muſt not be waſhed when taken out of the Churn, yet a great deal depends upon the getting the Whey well out, which can only be done by thorough working it in the Hands; and this is the more material, becauſe otherwiſe it would diſſolve and carry away a great Part of that Salt that was uſed in preparing it, ſo that it would fail.

As to the Quantity of Butter reaſonably to be expected in proportion to the Number of Cows, Accidents will make a great Difference; but in the Butter Countries they generally account that they may, one Year with another, expect from ten Cows a Firkin and half of Butter in a Week, in Summer; and from the ſame Number a Firkin in Winter. The Difference of feeding makes a great Variation in the Goodneſs of the Butter, and none is worſe than ſuch as is made when the Food is between wet and dry, as is the Caſe in the Beginning of Spring and latter End of Autumn, the Food being at thoſe Times between Graſs and Hay, and that Irregularity having a great Effect to the Diſadvantage of the Milk.

There are two Ways of making Salt Butter freſh, when there is Occaſion for it; and it is poſſible, by ſalting up the Butter in the cheap Times, and freſhening it when dearer, to make ſome Advantage.

The Method for the Service of a Family is by beating it up with new Milk; but when it is done by Way of Advantage, and for the Market, the Way is to cut it into thin Slices, and put it into the Churn where Cream is beating for freſh Butter. A good Quantity may be added in this Manner, but there is an Art in juſt hitting the Time. It muſt be put in when the other Butter begins to come, otherwiſe it will pervert and diſturb the Operation; but in this Manner it goes on very well with the reſt, and if not too long kept will, on being waſhed with the reſt, paſs with it as very good freſh Butter, not at all debaſing the Price.

CHAP. XX.

Of Whey Butter.

WHEY Butter is a Thing little known in London, but 'tis often made in the Country, for the Service of Farmers Families. It is like other Butter, but poorer and rank; and made from a Cream got out of Whey, as the other is from the Cream of new Milk. We have ſhewn how a Kind of ordinary Cheeſe is made from the Buttermilk, when new Milk is churned for Butter inſtead of Cream; and in the ſame Manner in this Inſtance, a poor Kind of Butter is made from the Whey of Curds made from new Milk.

All this depends upon one and the ſame Principle, which that all the ſucceeding Part might be naturally underſtood, we laid down in the Account of Milk. This is that there are in it three diſtinct Subſtances, an oily, a curdy, and a watery Part; now by whatever Method any one of the two firſt is ſeparated, the other will always, more or leſs, remain in the watery Part that is left. This is the whole Matter. When new Milk is wrought at once for the Butter, the curdy Part is left behind, and the Addition of Rennet to the Remainder makes a Kind of Cheeſe; and juſt ſo when Rennet is at firſt added to new Milk, the curdy Part only is ſeparated, the oily Part remaining, in ſome Degree, in the Whey; and this oily Part being ſeparated from the Whey makes the poor Kind of Butter, thence called Whey Butter.

The Method of making it is thus. When Curds have been made from new Milk, the Whey which is drained off is to be ſet in large Pans, or other broad and ſhallow Veſſels, and placed in a quiet Part of the Dairy, juſt as new Milk would be for Cream; there will riſe a Cream upon this, though not like that from new Milk, and it is to be ſkimmed off and churned in the ſame Manner.

The Butter this yields, we have obſerved, is very poor, but in ſome Places they enrich it, by adding a fourth Part of new Milk Cream to the Whey Cream; theſe, in any Proportion, mix very well together, and the Butter is the better according as the more of the new Milk Cream is uſed; that bringing it ſo much nearer the Nature of the other.

Beſide the inferior Quality of the Whey Butter, its Quantity in proportion to the Cream, is but poor. The ſame Meaſure of Whey Cream yielding but about half as much Butter as the other: neither will the Whey Butter ever come to a good Conſiſtence, nor will it keep; ſo that at the beſt it is but a very poor Matter: however, it may be worth the Farmer's while, in moſt Caſes, to make it.

CHAP. XXI.

A Method of taking off the ill Taſte of Milk.

WE have obſerved that however uncertain we may remain, as to the Cauſe of the ill Taſte Milk has at certain Times, yet the Effect is conſtant, and is very prejudicial to the Farmer; the Taſte being communicated from the Cream to the Butter, and reducing its Price and Eſtimation. To the Methods we have laid down for the preventing and remedying of this Evil, we ſhall here add a new and very particular one, the Invention of Doctor Hales, an Author not more diſtinguiſhed by his Genius, than by the conſtant Application of it for the Publick Good.

We have occaſioned the Method propoſed by the Gentleman, to be tried, and have found it anſwer ſo well that we ſhall not ſcruple to aſſure the Farmer, it is not more ſingular than ſucceſsful. The Inſtrument to be employed for this Purpoſe is very eaſily made and of ſmall Expence, and the Uſe of it very familiar. We ſhall therefore adviſe every Farmer to have one of them, and never to fail of uſing it when he perceives his Milk to be ill-taſted, from whatever Cauſe that may ariſe.

The whole is no more than this. A round Tin Box is to be made, of ſix Inches Diameter, and two Inches in Depth: the Lid of this Box is to be pierced full of Holes, they ſhould be about a quarter of an Inch diſtant from one another, and a twentieth of an Inch in Diameter. A Tin Pipe or Nozzel is to be ſoldered into the Middle of the Lid, and to riſe to ſome Height above the Surface, ſo as to receive ſecurely the End of a long Tin Pipe, through which the Air is to be conveyed into the Box; through the Holes of which it is to be blown up again through the Milk; this Tin Box being placed at the Bottom of the Veſſel.

The Tin Pipe that goes into this Nozzle is to be a little more than half an Inch in Diameter, and two Foot or more in Length, according to the Depth of the Veſſel.

To the Top of this ſtrait Pipe is to be jointed and ſoldered on another at right Angles. This ſhould be of the ſame Bigneſs with the other, but it need not be more than ſix Inches in Length.

To the End of this that is free, a Leather Nozzle or ſhort Pipe is to be fixed, and then the whole is compleated.

The Cover or Lid is beſt made deeper than the Box, and ſcallop'd in the Part that goes in; this lets the Air Holes have free Paſſage, and there is to be a Row of them on the upper Edge, where it is not received into the Box.

Every Tinman will be able to make this Inſtrument, and the moſt ignorant Servant may be inſtructed to uſe it: the Principle whereon its Benefit depends is this. The ill Taſte of Milk is ſo lightly mixed with it, that it may in a great Part be carried off, by blowing a Quantity of Air in diſperſed Particles through it; and this

this is to be done very conveniently by the Inſtrument now deſcribed.

The Tin Box is to be placed in the Middle of a large Veſſel, into which the Milk is to be poured as it comes from the Cow. The Tin Pipe is to be put into the Nozzle prepared for it, and when this is well fixed the Milk is to be poured in. Then, the Box being kept firmly at the Bottom, the Noſe of a Pair of common Bellows is to be put into the Leather Nozzle at the Top, and a Perſon is to blow for ſome Time.

The free Air is thus taken in by the Holes at the Back of the Bellows, it is forced down the Pipe by the Strength of the Blaſt, and it riſes through all the Air Holes in the Box, and thus paſſes in ſo many ſmall Streams up through the Milk.

When the Milk is but ſlightly ill taſted, it is thus to be poured into the Veſſel, as it comes from the Cow, and about forty Minutes blowing will perfectly ſweeten it; but when it is very rank the beſt Method is to make it ſcalding hot, and then pouring it in, to continue blowing till the bad Taſte is perfectly gone.

This Method, under proper Management, will make, at any Seaſon, perfectly fine Butter out of ill taſted Milk. In this laſt Caſe a great deal of Care muſt be taken not to burn the Milk to the Veſſel in heating; and it ſhould be kept warm during all the Time of the blowing.

The Author of the Experiment tried it upon the Milk of a Cow fed with Cabbage Leaves for eight and forty Hours; and though the Milk was very ill taſted in itſelf, it became perfectly ſweet in ten Minutes blowing. This was an Experiment with only a Gallon of the Milk, and it was kept hot by being ſet in hot Water during the blowing. The Cream produced by this had not the leaſt ill Taſte.

Some Caution muſt be uſed in blowing into large Quantities of Milk, becauſe of the Abundance of Froth that will riſe. If the blowing be too violent, this will ſwell over the Top of the Veſſel, therefore it is to be managed gently. The blowing muſt not be ſo briſk but that a Perſon ſtanding by may break the Bubbles, and keep the whole within Bounds; it will take ſomewhat the more Time the ſlower the blowing is performed, but the Buſineſs will be done as effectually.

But though the blowing may be performed more gently or more forceably, and the Effect be the ſame in the End, the Heat of the Milk muſt be carefully obſerved, for otherwiſe, when the ill Taſte is conſiderably great no Art will get it away.

The Experiment Dr. HALES tried, by feeding the Cow on Cabbage Leaves, was a very fair one for this Purpoſe; for excepting Crow Garlick, which the Creatures ſometimes eat in the Fields, there is nothing that gives the Milk ſo laſting an ill Taſte. A Cow's Milk will be made rank by Cabbage Leaves a Week after the Time of her eating them.

Crow Garlick gives ſo ſtrong a Flavour to the Milk, that no blowing will take it perfectly off when it is cold, though it abates it ſenſibly: but if the whole be kept warm for ſome Time, and well blowed, the Scent and Taſte will be carried entirely away.

When Milk is to be blowed in this Manner, for the taking away its ill Taſte, it will be proper to mix a little Water with it firſt. This Water ſhould be cold in Summer, if the Milk be blowed cold; and warm in Winter: but if the Milk be heated in order to the perfect cureing it by blowing, then the Water ſhould be put to it warm.

It is found by Experience that the Cream ſeparates better from Milk for the Addition of a little Water in the common Way of Management; for it thins the whole, and by that Means the Cream more eaſily diſentangles and ſeparates itſelf. In the Method of blowing it anſwers a double Purpoſe, it renders the whole Body of the Milk thinner, ſo that the Air paſſes more thoroughly and freely between its Parts, and the Surface is leſs frothy; ſo that the blowing may be briſker, and therefore the Operation ſhorter, and the Cream always riſes after this in a very free and perfect Manner.

There is one very peculiar ill Taſte that Milk has, and conſequently the Cream riſing from it, and the Butter made from that: this is a dead offenſive Flavour, worſe by much than any of the rank Taſtes named already: it riſes from the Cow's drinking ſtagnating, foul, and ſtinking Water. The Farmer ſhould, by all Means, prevent it, for it not only hurts the Credit of his Dairy, but endangers the Health of his Cattle; on this we ſhall treat farther in its proper Place, when we come to conſider the Diſorders of Cattle, their Cauſes and their Remedies; what concerns us here to obſerve is, that the ill Taſte may be got rid of by this Method of blowing Air through the Milk: but it requires the whole to be kept warm, and the blowing to be continued ſome Time.

All the ill Taſtes that happen to come into Cream are firſt in the Milk, and the beſt Way of attempting to remove them is always in the State of Milk, before the Cream is ſeparated.

In ſome of our Counties, when they perceive their Cream to be ill taſted, they heat it ſcalding hot, ſtirring it all the Time it is heating, and alſo till it cools again; and in other Places they heat the Milk for this Purpoſe before it is ſet for the Cream. Both theſe have a good Effect; but probably the heating of the Milk, when properly managed, will be found the beſt Method.

With reſpect to the curing the ill Taſte, by this Method of blowing, it muſt always be done to the Milk, not the Cream, for many Reaſons. It is more conveniently performed in the thin Body of the Milk, than in the thick Subſtance of the Cream: the thick Body of the Cream ſends up a Froth in the blowing, which is quite unmanageable: and what is much more eſſential, the Matter which cauſes the ill Taſte is much more difficultly removed in the Condition of Cream.

We have obſerved that the Addition of Water to the Milk aſſiſts and ſhortens this Operation, by thinning the Body of it; and from the ſame Reaſoning it muſt be more tedious, as well as more difficult, to get it out in the State of thick Cream; and ſo it is found upon Trial.

Theſe are the Reaſonings and Obſervations

of that excellent Philoſopher, confirmed and extended by ſome few Trials; the Succeſs of which ſeems to promiſe, that there will be great Advantage to the Dairy, in bringing this new Practice into general Uſe. We are ſenſible it will ſeem ſtrange to the Country People at firſt; but a fair Trial will recommend it to them, and it will ſoon be univerſal.

CHAP. XXII.

Of the Uſe of the Barrel Churn.

TO this general Account of the making of Butter, we ſhall join for the Sake of thoſe who like Improvements, the Manner of uſing the Barrel Churn: how far it is to be eſteemed we have ſaid already, but when it ſhall be introduced into any Dairy there requires a particular Management of it; and without the Knowledge of that the Farmer may never come at its real Advantages.

The beſt Way of making Butter with this, is out of Cream got in the uſual, careful, and cleanly Way, as we have deſcribed it before.

This is to be ſtrained into the Barrel Churn, as into the other, and the Advantage is, that turning upon a Spindle the Motion of this Churn, if well managed, is more regular than that of the other. But at the ſame Time we are to tell the Houſewife, that there requires a great deal more Skill in the Uſe of it.

The greateſt Miſtake I have been uſed to ſee made with this Churn, is the turning it about too quick. This is a very natural Error; for thoſe who know the Value of quick Strokes in the other, naturally fancy the quicker the Motion here the better; but the contrary is true, for I have ſeen Butter made and unmade again many Times over, by working it in this Manner.

On the contrary the right Rule is, that the Turning be gentle, ſlow, and ſteady; for this ſoft Motion on the Spindle is equal to a very ſharp beating in the downright Way. When this turning is done in the right, even, and eaſy Manner, the Butter comes quick, and comes very pure and fine.

It is naturally hard, ſweet taſted, and will keep; whereas the ſingle Article of too violent turning will make the very ſame Cream, in the ſame Churn, yield a ſoft, bitter Butter, that will not keep. One Thing farther muſt be obſerved, which is, that this gentle Motion muſt be kept up without Interruption, from the firſt Turn till the Butter comes, for all goes backward upon ſtoping. When the Motion has been too briſk, and the Butter is near made by it, I have ſeen, that on ſtopping a Minute only, the Cream and Buttermilk have mixed again almoſt as entirely as before, and the whole Work was to have been done over again, little otherwiſe than as if the Cream were then put freſh into the Churn.

We have told the Houſewife ſhe is to ſee the Barrel Churn turned conſtantly, without ceaſing, till the Butter comes: ſhe needs not to open it to examine into this, for ſhe will know by the Sound: there is a particular ſquaſhing Noiſe in the Churn when the Butter is come, which is quite different from what the Cream made in it before: when this is heard ſhe may be as ſure the Butter is made as if ſhe could ſee it; and then ſhe is not to order the Servant to ſtop, but only to turn more ſoftly and gently than before. This ſerves to finiſh the Separation of the oily or buttery Parts, and to bring them together into a Lump or Maſs: this muſt be continued half an Hour, and by that Time all will be perfectly done.

The Butter is then to be taken out of the Churn, and well worked with the Hand; and the Salt mixed with it according to the Intention of ſpending it freſh, or keeping.

In this and all other ſalting of Butter, it is a good Method to have the Salt beat to Powder: ſome have uſed Baſket Salt, becauſe of its Fineneſs, but it is dear and has little Taſte, in Compariſon of the other. Every Houſewife knows how to powder common Salt, by firſt drying it, and this is the beſt for the Uſe of ſalting of Butter.

In churning by the Barrel Churn all the ſame Cautions are to be uſed as in the other Way, reſpecting the Seaſon of the Year and Condition of the Veſſels. The Churn of this Shape muſt be kept as carefully and perfectly clean as the other: in Summer it muſt be well cooled from the ſcalding, or occaſionally freſh cooled, juſt before the putting in the Cream, with cold Pump Water; and in Winter it ſhould be left warm from the ſcalding. In theſe and all other Reſpects, the Difference only is in the Manner of giving the Motion to the Cream, and the whole Procedure, from the ſtraining in of the Cream to the working up of the Butter, is to have no Difference.

CHAP. XXIII.

Of Cheeſe.

CHEESE is the Article next in Conſideration to Butter, when we are treating of the artificial Products of the Farmer's Stock; it is made, as we have ſhewn in general before, of the curdy Part of Milk, as Butter is of the oily; and according to the Condition of the Milk, and other Circumſtances, it becomes of various Kinds, Taſtes, Qualities, and Prices.

All Cheeſe is the curdy Part of Milk, ſeparated from the Whey: but in ſome Kinds it is only the curdy Part, without the oily or buttery; and in others it is the whole mixed together, only the Whey being ſeparated: there are alſo Kinds of Cheeſe that have different Proportions in this Mixture. In general, as it is the curdy Part of Milk that gives the Conſiſtence and Form to Cheeſe, ſo it is the creamy or buttery Part mixed therewith, that gives it the Mellowneſs and Richneſs.

The Farmer's Servants well know what Cheeſe that is which is made of new Milk Whey, whence all the Butter has been taken; and the Cheeſe of Parma, and other of the Italian Dairies, ſhews us how excellent a Production it may be when the whole of a rich Cream is mixed among the curdy Part in the working.

We

We have ſome Counties in ENGLAND remarkable for the good Cheeſe they produce, and others for the bad: this has by ſome been laid entirely upon natural Faults, as the Soil and Graſs; but it is in a greater Meaſure owing to the different Conduct in the Dairies of thoſe ſeveral Places. We ſhall ſhew in the ſucceeding Chapters, that a good Houſewife will make good Cheeſe any where. We do not mean by this that the Milk produced by the worſt Food, will yield as good Cheeſe as that produced by the beſt, the Folly of ſuch an Aſſertion would be obvious to every one; but what we would have the Houſewife underſtand is this, that when the Food is the ſweeteſt, richeſt, and beſt in the World, a bad Manager may make bad Cheeſe out of the Milk; and on the contrary, that one who underſtands how to make the beſt of indifferent Advantages, will make good Cheeſe upon poor Land.

There are two Ways in which Cheeſe is naturally ſpoiled by the Paſturage of the Cattle: the one is when the Food is ſo poor that it impoveriſhes the Milk, ſo that its curdy Part has neither the true Strength nor natural Flavour: and the other is when Weeds grow in Abundance among it, which give it an ill Flavour, the Principal of theſe are Melilot and Garlick. As to theſe the Remedy is eaſy, for they may be pulled up: as to the other there is no Way of mending it, unleſs the Farmer have got better Paſtures, into which he can put them; if not he muſt be content with indifferent Cheeſe.

It will then become the proper Conſideration, whether he ſhall engage in the Cheeſe Way at all: and this he muſt learn by Trial of the Milk, to the two different Purpoſes of Butter and Cheeſe.

Although we cannot enter into the Secrets of Nature, ſo far as to penetrate Cauſes always, we have at all Times our Eyes open to Effects: theſe are ſo many Principles on which to found our Reaſonings, or what is better our Conduct; and theſe will be ſufficient for the Farmer's Purpoſe.

There are Paſtures that yield a Milk fit for Butter, but not for Cheeſe, and others that yield ſuch as is excellent for ſome Kinds of Cheeſe, but unfit for Butter. Therefore when the Farmer firſt ſets himſelf down upon his Land, he is to conſider firſt, which is the moſt profitable Manner of employing his Dairy in his Situation: if the Paſturage be equally proper for either Commodity, then let him principally turn his Thoughts to the making that which is moſt marketable; but if it will only ſerve well for one, let him take that, which ever it is; for Cheeſe and Butter are Things for which there will always be a Demand every where, although not equally in all Places.

Now when the Farmer ſhall find that his Land does not yield a Milk that gives good Cheeſe, let him try it for Butter: if it yields that good in its Kind, and plentiful, let him fall upon that Branch: but if it be really poor, and will yield neither well, then let him take the moſt ſaleable Article, which we ſuppoſe to be Cheeſe, in the preſent Caſe, and make the beſt he can of his Milk that Way. If he cannot make ſuch as is of a ſuperior Kind, a worſer Sort will ſtill fetch a Price; and we have told him how much may be done by good Huſbandry, even out of the worſt Materials.

Let him examine what is the Cauſe of his Cheeſe being bad, and remedy it as well as he can; if not at once yet by Degrees, and that according to the Nature of the Fault. The firſt Thing he is to do is to get the worſt Weeds out of his Paſtures; and then let him, by the ſeveral Means we have laid down in the former Parts of this Work for improving of his Land, ſet about the Work of amending in earneſt. A little Expence will go a great Way in the Improvement of Paſture Grounds, if laid out with Diſcretion; and he will have the Satisfaction of every Day receiving more and more the Fruits of his Care and Expence in his Produce.

Having thus prepared the Farmer for getting over the greateſt Difficulties he can meet with in the Cheeſe Manufacture, we ſhall lead him to the Practice; and ſhall begin by explaining to him the Nature, and directing the proper Management of the Article he uſes for curdling his Milk, this is what is commonly called the Rennet, or Rennet Bag.

CHAP. XXIV.

Of Rennet or the Rennet Bag.

CHEESE, we have told the Farmer, is the curdy Part of Milk ſeparated from the reſt, at leaſt from the watery Matter, in which it is originally mixed in the natural State: the firſt Thing to be conſidered therefore is, how to get this Curd ſeparated. It is a Property of Milk that it will curdle with any Acid whatſoever: this curdling is the Separation whereof we ſpeak, it is the gathering together of the curdy or cheeſy Part ſeparate from the Whey.

As any Acid or ſour Matter whatſoever will anſwer this Purpoſe, the Farmer has his Choice of a great Variety, but finding nothing agree ſo well, in all Reſpects, with the Milk as Rennet, that is the only one he uſes. This is a very natural Preference, for moſt of the other Acids or ſour Liquors are either of mineral or vegetable Origin: of the firſt Sort are Spirit of Vitriol and the like, and of the latter Juice of Lemons and Vinegar; now Rennet being an Animal Acid naturally agrees better with an Animal Fluid, ſuch as Milk, than one of ſo different an Origin as any of the before-mentioned.

There is in the Stomachs of all Animals an Acid or ſour Juice: Nature has given them this to aſſiſt in the Digeſtion of their Food, and it is in various Degrees in different Animals; and in the ſame Animal alſo, at different Periods of its Life, according to its Degree of Health.

Of all theſe Acids of the Stomach of various Animals, there is none ſo gentle and ſo certain of always having an equal Degree of Strength as that of a ſucking Calf. This therefore is what the Farmer prefers to all others, and is what he calls his Rennet or Rennet Bag.

That he may always have it in Perfection, we ſhall tell him what is its proper Condition. The

Rennet Bag is properly the Stomach Bag of a young ſucking Calf, that never taſted any other Food but Milk, and where the Curd lies undigeſted.

In the Spring Seaſon let the Farmer recollect the Occaſion he ſhall have for theſe Bags, and get himſelf a ſufficient Store of them. And he muſt order and prepare them in this Manner.

Firſt let him open the Bag, and pour out the Curd and thick Subſtance into a Baſon, leaving the reſt that is not curdled in the Bag.

Then let the Curd in the Baſon be carefully examined and picked clean. There may be Specks of Dirt, Hair, or other Foulneſſes among it; theſe muſt be all taken out, and the Curd is then to be waſhed in cold Water ſeveral Times. By this Means it will become perfectly clean and white. When thus cleaned it muſt be laid on a clean Cloth to drain, and then put into a clean Diſh; in this it is to be ſprinkled well over with Salt, uſing a Handful or more to this Purpoſe, and with the Hand rubbing well in the Salt to every Part of the Curd.

When the Curd is in this Condition let it be covered from Duſt, and let the Bag be cleaned. This is to be done by waſhing it ſeveral Times over in cold Water. When it is perfectly clean let it be rubbed well with Salt, and then put in the Curd, which has been ſo well cleaned, with the Salt among it. Finally let the Outſide of the Bag be alſo well rubbed over with Salt.

There is a great deal of Nicety and Care to be uſed in this Preparation of the Rennet Bag, for on that depends its Value.

When a ſufficient Number are thus got ready, let them be all laid together in a Pot, and the Pot tied down carefully. Now the whole Work is done, except what is to be the Effect of Time. Theſe Bags will keep without any Danger of ſpoiling, and they are in their full Perfection a Year after the preparing them.

This is the right Preparation of Rennet, and a moſt ſurpriſing Thing it is that all this waſhing and cleaning cannot remove or get out the Acid of the Stomach from the Curd, but that it perfectly anſwers the Purpoſe of curdling the reſt of the Milk, whenever the Farmer pleaſes; and that in a Manner greatly preferable to any other that can be named.

Though the Rennet is beſt after a Year's keeping, it may be uſed freſh and new; but the Effect is not ſo good. The Curd gets its right Condition from the very Time of its being ſeparated by the Rennet; and a Fault at this Time is not to be remedied afterwards. When the Rennet is freſh, the Curd is not made ſo firm and ſtrong; and the Cheeſe never gets a good, firm, and even Conſiſtence; therefore it is better the Farmer purchaſe ſuch as are of a right Age, than uſe his own too ſoon.

The old Way of managing the Rennet Bag was, after a very ſlight cleaning, to hang it up to be ſmoak-dry'd in a Chimney-corner; but that is by no Means ſo good a Way as the ſalting and potting a Number of them together: it is neither ſo cleanly, nor does it keep the Rennet in the needful Degree of Strength.

We have ſhewn the Farmer the proper Way of preſerving his Rennet Bag, but there yet remains an Article very well worthy his ſtrict Notice and Attention; that is the ſeaſoning of it. This is to be done in the following Manner.

When the Bags have been kept a Year, let one of them be taken out of the Pot and opened. Let the Curd be emptied out into a very clean Marble Mortar, and have its wooden Peſtle alſo thoroughly and nicely clean: rub and grind it well by itſelf firſt; and then add to it the Yolks of three new laid Eggs, and half a Pint of fine rich and perfectly ſweet Cream; rub and grind theſe together, and when they are well mixed, dry before the Fire one Blade of Mace, one Clove, and about eight Grains of Saffron: when theſe are ſo dry that they will rub to Pieces, powder them in a ſmall Mortar and throw the Powder to the other Ingredients; then work all well together again, till it is ſo perfectly mixed as to appear but one Subſtance. When the whole is thus thoroughly blended let it be put up in the Bag again.

Then make a very ſtrong Brine of Salt and Water, by boiling them together; let this ſtand to ſettle, and ſtrain off the clear Liquor into a clean earthen Pan. Take about half a Gill of the Curd out of the Bag, and mix it with this Brine. This done cloſe up the Bag again, and hang it up with the Brine, putting in four or five Wall-nut Leaves.

The Rennet being thus perfectly prepared, is to be ſet by for a Fortnight, and will then be fit for Uſe.

We have here ſet down at large the Management of one Bag; and according to this the Farmer muſt dreſs all the reſt; and his Care muſt be to do them one after another, in ſuch Time as he ſhall want them; ſo that he may always have one under another, and may never be obliged to uſe any one that is not duly prepared, and that is not a full Fortnight old in the Brine.

Some uſe leſs Care than this in the preparing of their Rennet, but it is ſparing Trouble in a very wrong Article; for not only the Rennet is ſharper, and goes farther this Way than any other, but the very Goodneſs of the Cheeſe depends, in a great Meaſure, upon it.

Some on the contrary uſe more Care and Caution: thus it is not unuſual to add more Articles in the ſeaſoning: and others boil a handful of white Saxifrage, or ſome other Herb, in the Brine: there is little Harm in theſe Things, but they are needleſs. We are for delivering fully every neceſſary Article, and caution the Farmer ſtrictly and exactly to obſerve them all; but we would not load him with unneceſſary Trouble.

This is the needful Preparation for the making of Cheeſe in general, and we ſhall now proceed to the applying it to the ſeveral Kinds, according to the moſt ſucceſsful Manner of making them in thoſe Places which have been famous for them; and whence many of the Kinds are named, beginning with that Cheeſe which is, in a Manner, univerſal; and which is, when well made, very good every where.

CHAP.

CHAP. XXV.

Of new Milk Cheese.

NEW Milk Cheese, otherwise called Morning Milk Cheese, is a Kind of general Production of the Dairy, like fresh Butter. 'Tis made almost every where, and in most Places is very fine; but it must differ according to what we have said before of the Consequences of the Variation of Pasture; this, however, though it encreases or debases its Value, makes no Alteration in the Manner of preparing it, which is to be thus done.

In the Morning, toward the Time of the People's coming in with their Milk, let a clean and large Tub be set ready; and let the Milk brought in the Evening before, be very carefully skimmed.

Let the new Milk, warm as it is from the Cows, be strained through the Strainer we have before described, into this clean Tub, and then pour through the Strainer the Cream taken from the last Evening's Milk. This mixed with the new Milk will give it such a Richness, that the whole will often be equal to what is sold in LONDON, under the Name of Cream.

This is too rich alone, and therefore it is to be a little reduced, and at the same Time prepared for turning the better by some hot Water. This is to be poured in in such a Quantity as will serve to make the whole tolerably hot, which scalds the Cream.

When this is done the Business is to get it cold a little; to this End it must be moved about with a Dish, till it is no more than luke-warm.

It will now be in a Condition to receive the Rennet.

As to the Proportion of Rennet to Milk, that differs according to the Strength of the Rennet; but as we can very well determine the Strength of such as shall be made according to the Directions, we may be sufficiently exact on this Head. The Strength of the Rennet made thus is such, that a Spoonful is a very good Proportion for three Gallons of Milk; so that if the Quantity be one and twenty Gallons, the Farmer will know he is to put in seven Spoonfuls of Rennet, and in the same Proportion he is to use it, let the Quantity be what it will.

When the Farmer has computed, from his Quantity of Milk, how much Rennet he shall want, there will require some Care in the drawing it from the Bag. He must do this steadily and evenly, without stirring the Bag. When he has got the due Quantity out he must strain it very carefully into the Milk. Let him not wonder at our recommending so much Care in this Respect, for if the least Particle of the Curd of the Rennet fall into the Milk, it will be unseen among the Curd it brings on in the whole, and then mixing up with the rest in the making of the Cheese it will taint and corrupt the Spot where it is; and every one accustomed to this Commodity, knows how dangerous it is to get a corrupt Spot, it never fails to spread and taint farther.

When the Earning or Rennet is put in, the Vessel is to be covered, and all is to stand quiet for half an Hour. This is the Time needful for the Operation of turning the Milk, that is, for collecting the curdy Part separate from the Whey: at the End of the half Hour the Cover is to be taken off, and if it be not come, that is, if the proper Seperation be not made, it is not to be left longer for that Purpose, for the Expectation would be always fruitless, and the Loss of Time prejudicial; but more Rennet is to be put in. Beside the Difference of Strength in the Rennet itself, there is a very great Variety in Milk, some requiring more of the same Strength than other.

When the fresh Rennet is put in, the Vessel is to be covered up as before; and opened at Times to see the Effect. As soon as the Separation is well made, the Curd must be well toss'd and worked about in the Whey. The best Method of doing this is first with a shallow Bowl, and afterwards with the Hands.

The Bowl is to be used in rummaging and tossing it to and fro in the Whey; and when this has been done sometime, it is to be wrought and moulded, and worked together between the Hands, and then pressed forcibly down to the Bottom of the Tub.

The Curd being got to the Bottom, the Whey is to be skimmed off with a shallow Dish; and while this is doing the Cheese Fat is to be got ready to receive the Curd.

The Curd is to be lifted up with the Hands and broke, and pressed down into the Fat.

When the Fat is well filled, the Cheese Board is to be laid over it, and a small Weight put upon it. In this Condition it is to be left till all the Remainder of the Whey, not separated by the working in the Hands, is pressed gently from it.

When it has done dropping let the Housewife wet a large Cheese Cloth, and lay it over the Board, and then turn the Cheese upon it. Then she is to lay the Cloth into the Fat, and put the Cheese in again. She is now, with a thin Slice, to press down the Sides every where, then turning the Cloth over it, it is to be carried to the Press, and there pressed with a good Weight.

It is to be in its present Condition half an Hour in the Press; after which it is to be turned into a dry Cloth, and then put there again.

This Practice is to be repeated again every two Hours; each Time using a fresh dry Cloth; and it is to continue in the Press till the Evening of the next Day; only the last Time it is turned, it is to be put into the Fat without any Cloth at all.

When it is, after this, taken out of the Press, it must be put into a Tub, and rubbed on both Sides with Salt. There it is to remain all Night; and next Morning it is to be rubbed again with Salt, first on one Side and then on the other, and left upon the Brine which came from the first and the succeeding Saltings. When it has lain thus three Days it is to be taken out, and laid on a Shelf to dry; and while it is drying the Housewife must continue her Care of it, wiping it once every Day perfectly clean with a dry Cloth,

and then turn it on the dry Side; this is to be done every Day, till it be perfectly dry. At firſt it is fit the Cheeſe dry ſomewhat quicker than afterwards, which may eaſily be contrived by changing the Place.

This is the whole Proceſs that is to be followed in making the new Milk Cheeſe, we have been the more particular in deſcribing it, becauſe it will let the Reader into the general Manner of doing the reſt.

CHAP. XXVI.

Of a one Meal Cheeſe.

THE Farmer will know we mean, by a one Meal Cheeſe, ſuch as is made of the milking of one Morning or one Evening only; but the Morning is the proper Time, becauſe the Day is then before him for the Buſineſs. The Reader unaccuſtomed to theſe Things might ſuppoſe we mean a Cheeſe to be eaten at one Meal; but we muſt keep the accuſtomed Terms: all we can do is to explain them.

A one Meal Cheeſe might properly be called a new Milk Cheeſe, or a Morning Milk Cheeſe, rather than that laſt deſcribed, becauſe it is really made of new Milk only, or of the Morning Milk alone, whereas that has the Addition of the Evening's Cream; but we ſhall not be underſtood by thoſe for whoſe Sake we principally write, if we do not keep to the Uſe of thoſe Terms they are accuſtomed to hear.

The one Meal Cheeſe is made, we have obſerved already, of the Morning's Milk, and nothing more, and the Method of making it is the ſame with that before deſcribed, only that it is not ſo difficult in the firſt Part, becauſe there is nothing of that Trouble of mixing the Cream, and preparing the whole for the Rennet.

When a Cheeſe of this Kind is intended to be made, the Houſewife ſhould tell her Milk People of it, and give them a particular Caution to be quick Home with their Pails; for the moſt advantageous Way is, to mix in the Rennet when the Milk is warm from the Cow: it is in this Caſe to be ſtrained into a Tub, and the Rennet at once put to it in the Quantity before-mentioned. If the Milk be not warm when it is brought in, it muſt be ſet over the Fire to give it a little airing: but here a great deal of Caution is to be uſed, as to the Degree of Warmth: for a little Heat ſerves to make the Rennet take Effect, and the Curd ſeparates the ſooner for it, but on the other Hand, if the Milk be made too hot another Separation comes on, which is not intended in this Caſe, and this is the parting of the Cream from the Milk.

We ſee the Effect of heating Milk, whether in the common Way over the Fire, or in the Way for what is called ſcalded Butter, is always a raiſing of the Cream more freely and ſpeedily: now this is not intended in Milk deſigned for Cheeſe, for we ſee on the other Hand, a great deal of Cream is added to the Milk in the former Method of making the new Milk Cheeſe.

This is named to caution the Houſewife, that in following our Inſtructions for the Improvement of her Milk, ſhe may not, by exceeding the Bounds, ſpoil all. Some Warmth is neceſſary for the Rennet taking its proper and timely Effect, but too much ſeparates the Cream. We ſee that the Cream remains perfectly mixed in Milk as it comes from the Cow, and a leſs Warmth than this is ſufficient for the giving Effect to the Rennet; therefore let the Houſewife, whoſe Milk is not brought in warm enough, make it nearly as warm as when it comes from the Cow, it need not be quite ſo much, and while it is under this ſhe is ſafe from doing any Harm.

When the Milk has been made of a proper Warmth, and the Rennet is in, 'tis to be covered up till the Curd is formed; and then the Cheeſe is to be made, in all Particulars, juſt as that before deſcribed; that being the general Method, we ſhall in none of the following Inſtances repeat it, but only refer to it, unleſs when any particular Circumſtance requires ſome Variation.

Having mentioned what is called the one Meal, we muſt add the making of the two Meal Cheeſe; this is a Cheeſe made of two Milkings mixed together, and the common Way is to mix the Evening's and the next Morning Milkings for this Purpoſe.

In that Caſe the Cream is ſtirred into the Evening's Milk, and then the whole is mixed with the Morning's Milk: all this warmed a little together, till nearly as warm as the Milk when it comes from the Cow, and the Rennet is put to it, it is then to be covered up, and the whole to be managed into a Cheeſe as before.

There is another Sort of two Meal Cheeſe, which is made by mixing the Evening's Milk after it has been ſkimmed, with the Morning's entire, and this alſo is eaſily enough made into a Cheeſe, by firſt warming the whole over a Fire.

Theſe Cheeſes differ in Goodneſs according to the Quantity of Cream that is in them, and they are all, in their ſeveral Degrees, inferior to the new Milk Cheeſe deſcribed in the preceding Chapter. As that conſiſted of the Morning's Milk and Evening's Cream, it is the richeſt Cheeſe of this Kind. As to the others, the one Meal Cheeſe and the two Meal, are juſt equal in Goodneſs, when the Evening Milk is uſed with its Cream; but in this Caſe the Cheeſe is one Degree inferior to the other, as there the Cream of the Evening went to enrich the Milk of the Morning, without its own Milk. The third and pooreſt Kind is that made of the two Meals or Milkings, one of which has been ſkimmed. This reduces it toward the Condition of ſkim'd Milk Cheeſe; but however it is very ſuperior to what is made of ſkim'd Milk only, becauſe as that conſiſts of the Curd of Milk wholly, that had loſt its Cream, this is in Part compoſed of Curd with the Cream in the Milk, that of one Meal not having been ſkim'd. We ſhall add, for the Uſe of the poorer Farmer, and ſuch as have Occaſion for the moſt ordinary Cheeſe of all, the Manner of making it from Milk that has been ſkim'd entirely.

CHAP.

CHAP. XXVII.

Of skim Milk Cheese.

WE have come down gradually from the best Kind of common Cheese to this, which is the poorest and the worst. It is to be made with some Care; and indeed the Ingredient is so poor, that without more Caution than is needful when there are better Materials, there will be no making it at all.

When the Milk of two or more Meals has been skim'd for Butter, it must be poured into a Tub, and the first Thing is to taste it carefully, to find whether it begin to be sour, for on this depends the Manner of working it; if the nice and accustomed Taste of the Housewife cannot perceive any thing sour in it, she must put a Part of it into a Pot, and set it over the Fire, making it so hot that it shall be able to heat the rest thoroughly, to somewhat more than the Degree of Heat required in the preceding Directions.

In those Cases a richer Milk was used, so that there was Danger of raising and separating the Cream by too much Heat; but here there is so little that it is in less Danger of that Accident; and the Milk being poorer, is not so easily turned. It will require somewhat more Earning and more Heat for that Purpose.

This is the Method to be followed, if the Milk be perfectly sweet; but if on tasting it be found sour, or but inclined plainly to Sourness, it must not be set on the Fire, lest it should break: in this Case a small Quantity of Water is to be made thoroughly hot, and poured in to bring the whole to a due Degree of Warmth to receive the Rennet.

When the Rennet is in, the Vessel is to be covered, and after this the whole Process is to be repeated, till the Cheese is made in the same Manner as the former.

These are the several Cheeses made in common in all Places, and with which all Farmers should be acquainted; we shall now come to such as are more particular in their Kind, but most of them made to great Advantage.

CHAP. XXVIII.

Of Cheshire Cheese.

THE Soil and Pasturage in CHESHIRE, and the adjacent Parts, are very favourable for Cheese; we have observed, on entering upon this Article, that some Soils and Pastures are more, some less favourable, but none so much, at least none more than this.

To this happy Article, which they have from Nature, the CHESHIRE People add a particular Care in the making up of their Cheeses: otherwise there is not much particular in the Method, except what becomes needful from the great Size of the Cheese. We shall however lay down the whole Process, as we have obtained it from some of the greatest Dealers on the Spot; that the Farmer elsewhere, in the like Circumstances, may know how to set about the same Undertaking.

Cheshire Cheese is a new Milk Cheese of a very large Size, made from a Milk, which the Food of the Cows thereabouts renders particularly excellent for that Purpose. There is nothing more in the Matter, and the Way in which they make it we shall deliver presently; but first, for the particular Instruction of the Farmer, we shall acquaint him with their general Management of their Cattle.

The Time of the Year at which they make their fine Cheese, is from the Beginning of MAY to the End of SEPTEMBER: this they expect annually as the Season, and they manage their Milch Cattle accordingly.

In the Middle of APRIL they turn them out to Grass, they make Cheeses as soon as they begin this feeding, but the first are not the fine saleable Kinds, nor are brought to Market. They are coarse, poor, and ill-tasted, and are all consumed upon the Spot. The Pastures are too rank at this shooting Season of the Year, and the Consequence is, that the Cheeses made from their Milk partake of this Rankness, and they have it not only in their Taste but in their other Qualities: far from being of that regular and firm Texture, the Cheeses made afterwards have, these lose their Shape, swell and become full of Holes, so that they are neither well tasted nor well looking. Nothing can be so unlike what we commonly understand by the Name of a Cheshire Cheese, as what is made in CHESHIRE at this Time of the Year.

This may shew that the Effect really is owing to the Pasturage, in those excellent Cheeses we have from CHESHIRE; for we see, till the Pasture is come down from its own Rankness, it does not afford Milk fit for Cheese making there.

The People are so sensible they are to expect this, that they use particular Cautions always at that Season: they always boil a Part of their Milk, which they do not at other Seasons of the Year; but this does not answer their Purpose. However, as they are used to Cheese making they begin at this Season, and so long as it is bad they keep it for their own Use; nothing could inform them so well as Experience, when it becomes better; and finally, when it gets altogether fit for their Service in the great Way of their Traffick.

Some have attributed this Fault in the Cheese made early in the Year in CHESHIRE, to some particular Weeds; and Horsemint has been named as the Principal; but this is a palpable Error. Horsemint grows all the Summer, so that were it the Cause the Effect would remain. The whole Occasion is the particular Condition of the common Pasturage at that Season. This in the rest of the Year particularly favours the Cheese, but it is now too rank; and we very well know in other Instances, as well as this, the best Things may be faulty when they are in Excess.

It is not only before the right Season, but after it, that the Cheese of CHESHIRE is bad; we have named the Time of the Year at which the fine

Cheese of this County is made, which lasts only five Months: after this Period, though the same Care and Pains be used in making it, the Cheese grows bad again, and is not marketable; at least they do not carry it to Market, lest it should hurt the Credit of the Country: but they continue making it for some time, for the Use of their own People.

The Fault of the Cheese after MICHAELMAS, is of a very different Kind from that in Spring. In the Month of APRIL it is rank, and in OCTOBER it is poor. This is the greatest Proof that can be, not only that the Excellence of the Cheese of this County is owing to the particular Nature of the Pastures, but that this Article of Food to the Cattle is the whole Matter on which the Difference that good Dairywomen find in Cheese, in the several Parts of ENGLAND, depends. There is good Cheese made in SUFFOLK, and we see there is bad in CHESHIRE: but in general it is reasonable to conclude, that the Soil of CHESHIRE affords a Pasturage particularly fit, and that of SUFFOLK particularly unfit for Cheese.

We see the Progress of the Growth of Pasturage in CHESHIRE, marked exactly by the Condition of their Cheese. During the Summer, when that Food is in its regular and perfect Richness, Cheeses made there, though in the same Manner with those in other Places, excel those of any other Part of ENGLAND; but in Spring the Herbage is too rank, and they are destroyed by their own Richness, and in Autumn it is too weak, and the Cheeses grow poor.

As the People of CHESHIRE begin Cheese making before the Pasturage comes to be good, they continue it after it is decay'd; and this with very good Reason, for they could not any Way else tell exactly when to begin, or just when to leave off. By this Conduct they do not lose a Day of the Cheese Season; and as to what they make before and after the Season of its Perfection, they have a Home Consumption.

When they are convinced there are no more of the marketable Cheeses to be made, they continue that Work only till they have made the necessary Provision for Home; then they go to making of Butter, a great deal of which they salt, and this they continue till the Cows grow dry.

After this general Account of the Nature of Cheshire Cheese, and the Occasion of its particular Goodness, we shall give the Directions for attempting it in other Places, according to the Rules which are universally followed there; for in all the Country they have but one and the same Practice, and they very seldom fail in their Expectation, during the favourable Time of the Year.

CHAP. XXIX.

The Way in which Cheshire Cheese is made.

IN laying down the general Methods of making Cheese in CHESHIRE, we must observe that there are in this, as in all other Things, some Differences; there are People in CHESHIRE who make poorer Cheeses than others, but it is not to their Credit or Profit; and the Difference we observe in them, though in some Degree owing to the keeping, yet is also sometimes owing to the Condition in which they come from the Maker.

We have observed that the Cheshire Cheese is properly a new Milk Cheese. We have shewn, in the treating of the common Country Cheeses, that some make them with new Milk, enriched by the Cream of the last Milking, and others of new Milk, impoverished by an Addition of the skim'd Milk of a preceding Meal. In CHESHIRE their Pastures are so rich that they never find it needful to enrich their new Milk, for it will alone, with proper Management, make Cheese of the richest Kind that can be; but some of the CHESHIRE People impoverish their new Milk, by mixing the skimmed Milk of a former Meal, and this always debases the Nature and Quality of the Product.

This is the general Cause of the natural Poorness of such Cheshire Cheese as is inferior to the common Sort; but this is a Practice carried on by few. Having just mentioned this for the Sake of passing upon it a necessary Censure, we shall lay down that Method which may be called universal in the County.

They are in the first Place particular as to the Condition of the Cow: and this is a Caution that all Farmers would do well to take from them: they find by Experience, in this great Cheese County, that the Milk of a Cow which has just calved, is not so proper as that a few Days after; therefore they never take the Milk of any Cow for Cheese till she has been milked four or five Times.

This Caution being observed they use their whole Store of new Milk, a very little excepted, for their necessary Uses, in the Cheese Manufacture. When the Morning's Milking is brought in, they strain it warm into a large Tub, and put in their Rennet. Four Spoonfuls is the Quantity they usually allow to as much Milk as will afford a Cheese of a Hundred Weight; and there are Dairies of such Consequence in that County, that they turn out two Cheeses of about this Size every Day, during the five Months they are in the right Season.

They cover up the Tub, and when it has stood half an Hour they open it, and find the Curd formed. They are very cautious to hit the right Quantity of Rennet, which no Rule can determine, because of the Difference in the Strength: for too little does not give the Curd a due Consistence, and too much makes the Cheese bitter.

After half an Hour they uncover the Tub, and press down the Curd with a large skimming Dish; and when they have pretty well cleared off the Whey, they get to work upon the Curd with their Hands, which they break to Pieces in the most perfect Manner, working it a long Time for that Purpose.

This done, supposing it for a Hundred Weight Cheese, they add one Pound of Salt: this they work in, and mix thoroughly well with the Curd.

This done they put the Curd into a wet strong

ſtrong and large Cheeſe-cloth, and when they have got the Whey tolerably well drained out, they put it into the Fat, or Mould, for four Hours, with a good Preſſure, putting the Fat in the Cheeſe Preſs, and working it down pretty ſtrongly.

At the End of the four Hours they take it out, ſalt the Outſides, put it into a freſh wet Cloth, and put it into the Fat, and that into the Preſs again: here it is to be kept four Hours more; and in the mean Time a Quantity of good ſtrong Brine is to be made of Salt and Water, and put into a large Tub.

When the Cheeſe has been four Hours more in the Preſs they take it out, and put it into the Tub of Brine, and then let it lie eight Days, all the Time covered over with Brine, and turned once a Day.

At the End of this Time it is to be taken out, and laid to harden and dry. This is to be done in a particular Manner, and Preparation is to be made for it accordingly.

A Quantity of Ruſhes are to be cut up, and laid green on a large Board: on theſe the Cheeſe is to be laid when taken out of the Brine, and for the firſt Day nothing is to be done to it; the next Morning it is to be turned and wiped with a Hair Cloth all over; and this is to be repeated every Day for twenty Days.

At the End of this Time it muſt be removed from the Bed of Ruſhes, and laid on the Floor; and it is here to be taken up, and turned once in three Days, and at every turning it is to be rubbed; till it gets firm and hard: as this is the compleating the Work, it is to be done very carefully; for if the due Degree of Hardneſs be not given at this Time, the Cheeſe will be liable to Accidents in the keeping. Therefore it is an eſſential Point to let it lie long enough, and wipe it carefully.

When it is thus finiſhed and hardned, the laſt Thing is the rubbing it over with ſome Butter, and this, though it may ſeem more trivial than the reſt, is very eſſential: half a Pound of Butter is the proper Quantity for a Cheeſe of a Hundred Weight, and this ſhould be rubbed thoroughly in all over it, nothing more tending to preſerve the Rind in good Condition, and keep the Cheeſe ſound.

This is the Method obſerved in that famous Cheeſe County. They have Rooms built on Purpoſe, in many Places, for the drying of their large Cheeſes, and they raiſe the Floors ſeveral Feet above the Ground, to preſerve them from Damp. In many Places they uſe Shelves put round theſe Rooms, inſtead of uſing the Floor, which I think much the better Method, for the Cheeſes are more ſecure to be out of the Reach of Damp, and they are more eaſily turned, and more conveniently rubbed and wiped, which is very eſſential.

CHAP. XXX.

Of making Cheeſe like Cheſhire, in other Places.

WHAT I have written in the preceding Chapter, concerning the making of Cheſhire Cheeſe, is what I have collected from thoſe who are much concerned in that Product, and from what I have myſelf ſeen on the Spot: for I once, ſome Years ſince, made a Journey thither for that Purpoſe, and took Notes of every Circumſtance, intending to attempt the making a Cheeſe of the ſame Sort.

Having thoroughly acquainted myſelf with the Method of working, I ſet about it at Home, employing the moſt careful Servants that could be had, and over-looking every thing myſelf.

The firſt Trial did not ſucceed; and I made another; after the ſecond I made a third, and being very much bent upon the Thing, I repeated the Experiment oftener than a wiſe Man ſhould have done; for I found in the End I had been trying to make Brick without Straw, my Materials not ſerving me.

I was not at that Time ſo ſenſible as I am ſince made by Experience, that the Cheshire Manufacture depends, in a Manner, entirely upon the Cheshire Paſtures. It was plain the Food was of great Conſequence, and from the Failure of the Milk from one Paſture I tried that of another, and went the Round of all my own, and ſeveral of my Neighbours, but nothing would do. Some was too rank, and ſome too poor, but none came up to that excellent Richneſs of the Cheshire Kind.

This I have mentioned as a Caution to others: but there is no Need it ſhould prevent their making ſome Trials, only let them learn from this Experience, not to venture ſo many.

There may be Grounds that will afford a proper Milk; but from ſuch as do not, none can ever make this right Kind of Cheeſe.

Wherever the Farmer has upon his Hands a rich, ſhort, and ſweet Graſs, with numerous Blades, a full Body in each, and few rank Weeds among it, there it will be worth while to make a Trial; not to ſet aſide the whole Buſineſs of his Dairy for ſuch Trial, but to make one Cheeſe. Let him give the Experiment fair Play, by making it in the firſt or ſecond Week in June, which is the Time when the very beſt Cheeſes are made in Cheshire; and having made this Trial with all due Care, according to the Rules we have laid down, if it do not ſucceed let him give up the Expectation: if it do he has the Opportunity of making a Fortune.

Others beſide myſelf have tried with as little Succeſs, in various Parts of the Kingdom; but all this proves is, that we have not yet found any Paſtures like thoſe of Cheshire; but that is no Proof we never ſhall.

The Misfortune of theſe Cheeſes made in the Cheshire Manner in other Places, is that they will not keep their Conſiſtence; and when that is loſt they ſoon decay. The great Happineſs of the Cheshire Paſtures is, that they furniſh a Milk which has at the ſame Time great Richneſs and great Firmneſs in the Curd, which are the two Articles whereon the Firmneſs and Fineneſs of Cheeſe depend.

CHAP.

CHAP. XXXI.

Of making Sheeps Milk Cheese.

THE Reader who is unacquainted with these Subjects, will naturally enough suppose a Cheese made of Sheeps Milk must be a very poor one: hut this is a great Error. They prefer in CHESHIRE the Cheese of the neighbouring Parts of WALES, to the very finest of their own, giving thirty per Cent. more for it, and this is all made of the Milk of Sheep.

It is particular in Sheeps Milk that it abounds in Curd; all Milk, as we have observed, consists of the three Parts, Curd, Butter, and the watery or wheyey Matter; but it is the particular Quality of the Sheeps Milk, that it affords most Curd in Proportion of any other Kind.

It is natural also to this Curd to be tender; but there are Pastures on which the Sheep yield a Milk as proper for Cheese, as the Cows of CHESHIRE. These are principally in and about the Borders of WALES. I have examined them with Design to tell the Farmer in ENGLAND which of his own are like them, and I can give him some Hope of Success in this Article, if he will think it worth while to attempt the Manufacture.

DENBIGHSHIRE is the particular County where Sheep Milk Cheese is fine: this is as famous as the Cheshire of ENGLAND. The Pastures on which the Sheep feed there are hilly, the Soil rocky, and the Grass low, but very thick and entirely free from rank Weeds.

We have the same or very nearly the same Kind of Pasture in some Parts of HERTFORDSHIRE; and the Farmer will know it by the Shortness and dark Look of the Grass, and by the little blue Bell Flowers, which are the principal Weed that grows among it. In these Pastures Sheep yield a Milk, the Curd whereof is firm, and therefore there is all the Advantage, and little of the Inconvenience attending this Species.

The Cheeses made of this Milk are extreamly rich and mellow. They never have any great Degree of Hardness; but their Richness is always a great Recommendation, and another is their ripening very quick; for one of a moderate Size will be fit to eat in four Months or sooner.

This may very well tempt the ENGLISH Farmer to make a Trial, and the Price may encourage him farther. 'Tis a Cheese that in many Parts of ENGLAND brings from five Pence to seven Pence a Pound Retail; and might be set at a much larger Rate in LONDON.

We shall acquaint the Farmer with the Method of making it to Perfection; but shall first inform him what he is to expect by Way of Quantity from these new-fashioned Milch Cattle.

Five Ewes, upon a good Pasture, will give at the Rate of two Gallons of Milk a Day: upon an indifferent one they will give a Gallon and half: so upon this the Farmer may judge how many he will set aside for this Purpose of milking. He may count five Ewes as the same with one Cow, and he will not be much mistaken.

The Sheep are to be milked Morning and Evening, and when they are a little used to it will stand very quietly. The Milk of the Evening is to be strained into that of the Morning, and when the Milkers come in the next Morning the whole is to be mixed with what they bring in. This is the Custom in WALES, where they make these Cheeses best; so that the Sheep Milk Kind is always what we call a three Meal Cheese.

When the Milk is all mixed, a little of it must be heated, and that poured into the rest to make the whole of the same Degree of Warmth with that which just comes from the Cow. Then the Rennet is to be strained in, and thoroughly mixed with it. As to the Quantity, it is to be about one fifth Part more than is used for Cows Milk.

The Vessel is to be covered, and stand quiet till the Curd is formed, and after that the Procedure is to be much the same with that on other Occasions. The Whey must be skimmed off, the Curd must be well worked in the Hands; and afterwards put into a wet Cloth and press'd, but this Pressure must be continued six Hours.

At the End of that Time it must be taken out, and the Cloth shifted; the Outside must be then salted, and it must be pressed six Hours more, the other Side being turned upwards.

While this is doing a Bed of Rushes must be made upon the Floor, and the Cheese, when taken out, must be laid upon it, and in this Manner it must lie a Fortnight, taking up and turning it every Day; and remembering every Time it is taken up, to rub it softly but thoroughly all over, with a dry and not very coarse Cloth. In this Time, drying gently and leisurely, it will get some considerable Firmness, for a Cheese of so mellow a Kind; and when it is thus far prepared, it is to be taken from the Floor and laid upon Shelves, where it will dry more quickly than at first, and be thoroughly finished.

This is the Method of making a Sheep Milk Cheese entire, and a very excellent and valuable Kind it is; but there may be a Sort made with Sheep and Cows Milk mixed, which will answer the Farmers Purpose excellently in many Places, where his Pasture would not serve for the makeing Cheese from the Sheeps Milk alone.

There is a Season when the Sheeps Milk may be had in Plenty, and without Inconvenience: this is when the Grass Lambs are sold off fat: the Ewes will then yield a large Quantity of Milk, and that regularly for some considerable Time; they should therefore be milked, and the Produce mixed with the Cow's Milk for Cheese. We have mentioned how Sheeps Milk abounds with Curd; and how fine that is in its Kind: being mixed with Cows Milk, the Curd produced from both has the Advantage of each Kind, it gets Firmness from the Cow, and a delicate Mellowness from the Sheep.

This Curd is to be made into Cheese in the Way we have described for the new Milk Cheese, and it will excel any that is made of new Milk from the Cow alone. I have had Cheese of this Kind made upon my own Ground,

and

and when it has come to my Table ſome have taken it for one Kind of foreign Cheeſe, ſome for another; and every impartial Perſon has declared it better than moſt Kinds.

CHAP. XXXII.

To make a Nettle Cheeſe.

A Nettle Cheeſe is accounted, in many Parts of ENGLAND, a very dainty and excellent Kind; it is a very thin new Milk Cheeſe, with an exceeding fine and ſmooth Coat, that is the whole Matter. It differs from the common new Milk Cheeſes more in the Form, and the Manner of making and drying, than in any thing eſſential in itſelf.

The Reader has obſerved that for the drying of the CHESHIRE Cheeſes, which are large and thick, they uſe a Bed of Ruſhes ſpread evenly upon the Ground or Floor of the Room; and in the ſame Manner a Bed of common Nettles is the Matter on which theſe Cheeſes are dried, and from which they receive their Name; the Nettles upon this Occaſion are to be freſh cut, as the Ruſhes on the other; and the Manner of making the Cheeſe is this.

Let the Milk of the Morning's milking be taken for this Purpoſe, juſt as it comes in warm from the Cows, without any Addition or Mixture, for the enriching or impoveriſhing it; or the joining with it the Milk of any former milking. Let this pure freſh Milk be ſtrained through the ſtraining Bowl into a large Pan, or ſmall Tub, and let there be immediately added to it as much Rennet as will be neceſſary to turn it. 'Tis then to be covered up half an Hour; then the Curd is to be preſs'd down, and the Whey ſkim'd off, and when thus ſeparated the Curd is to be wrought in the Hands. When it is well worked it is to be put into a Cheeſe Fat, not more than three Quarters of an Inch deep, and preſs'd to get out the Whey.

The very ſame Method is to be uſed that was directed for the new Milk Cheeſe, and by this Means there will be a very fine one Meal Cheeſe, thin and delicate, prepared, and ready for drying. It is then the Nettles come in Uſe. When it has been ſufficiently preſs'd it is to be laid on the Floor, which is to be firſt ſpread over with freſh Nettles, and another Parcel of the ſame is to be ſpread over it.

Care muſt be taken in the cutting and laying of theſe Nettles, for the Cheeſe is to have an even Coat, and that will depend entirely upon the Management in this Particluar. In the cuting then it muſt be obſerved, that only young Nettles are to be taken, or the tender Tops alone of ſuch as are more grown; and theſe, when they have been laid evenly upon the Floor, muſt be preſs'd down, and flatted carefully into an even and ſmooth Surface: this is the eſſential Article whereon the Smoothneſs of the Coat of the Cheeſe depends; and if there be any thicker Stalks, they will take Effect upon the tender Surface of it, and even any rumpled Leaf will have the ſame Conſequence. When the Bed is made flat and even, the Cheeſe is to be laid carefully upon it, and a Coat of the ſame Kind ſpread evenly over it. Every other Day freſh Nettles are to be brought in, and the Cheeſe is to be wiped and laid upon the new Parcel, covering it with freſh ones alſo. In this Manner it is to be kept till it is ripe and ready for the Table, and no Cheeſe ripens finer.

CHAP. XXXIII.

To make a running Cheeſe.

THIS is a greater Delicacy than the former, and is a richer Cheeſe, with the ſame Advantages of ripening; it is made thus. Mix together equal Meaſure of Stroakings of the Cow, and of rich Cream, put this in a clean Pan. Set it in a Pot of Water, that the Water may reach up on the Outſide as high as the Cream and Stroakings do within; then ſet the Pot on the Fire, till the whole be as warm as Milk from the Cow.

Take the Pan out of the Water, and put in as much Rennet as is ſufficient to turn it. Stir this well in, ſo that it may mix thoroughly, and then cover the Veſſel.

When it is come, preſs down the Curd, and take off the Whey: then heat the Whey ſcalding hot and throw it upon the Curds, and after this take up the Curd, which will now be in a Body: this muſt be done carefully with both Hands; and the Curd is to be raiſed up as whole as poſſible without breaking it, and ſo laid into the Fat; then place it in the Preſs, and put a ſmall Weight upon it; afterwards put on a larger, but don't bring it to the Screw Preſs, for it is too delicate for that forcible ſqueezing.

When the Whey is got out let it be taken out, ſalted a little, and laid upon a fine even Bed of Nettles. The Leaves of the Nettles ſtripped from their Stalks, ſhould be uſed for this Purpoſe. It muſt be ſhifted as the other, and will be very ripe in three Weeks or leſs. Three Pints of each of the Ingredients makes a proper ſized Cheeſe of this Kind.

CHAP. XXXIV.

Somerſetſhire Cheeſe.

THIS is a large and rich Kind of Cheeſe, named from the County whence it is brought, and where it is principally made. The Bigneſs is a very material Article, for I have ſeen the ſame Kind of Cheeſe exactly, made ſmaller, and it has been not at all particular, or ſcarce ſeemed of the Nature of the larger. What is farther ſingular in it is, that there is Butter worked into it, which greatly helps the Mellowneſs.

This is to be made thus. Let the Milk of twelve Cows be ſet over Night for Cream; and in the Morning let the Milk of the ſame Cows be brought into the Dairy warm from them. Let the Cream be carefully taken from the overnight's Milk, and mix'd with this Milk of the Morning, let all be ſtrained together into a large

large Tub, and as much Rennet put in as will be ſufficient to turn it. Let it be covered up for half an Hour, then open it, break and preſs down the Curd; ſeparate the Whey, and when the Curd has been well worked in the Hands, to a Cheeſe of this Size there muſt be allowed three Pounds of freſh Butter. This muſt be well worked into the Curd with the Hands, and a little Salt ſprinkled over it, and alſo worked in.

It is then to be put into the Preſs in a large wet Cloth, and it muſt be turned very frequently, every Time uſing freſh wet Linnen, till toward the laſt, and then there muſt be three or four dry Cloths.

When it is put in for the laſt Time it muſt be ſomewhat firmer preſſed than before, and it ought to remain in the Preſs forty Hours. When it is taken out of the Preſs it muſt be waſhed over with Whey, and laid in Cloths till dried. It is finally to be laid on a Shelf, that it may dry perfectly, and there muſt be turned very frequently, and every Time carefully wiped. It will, according to its Size, take a conſiderable Time in drying, but it will become in the End a very rich and fine Cheeſe.

CHAP. XXXV.

Of the early Uſe of Wool in the Eaſtern Countries.

WE have ſhewn our Huſbandman the proper Management and various Uſes of Milk, the Produce of his Cows, and we are now to conſider the Nature, Qualities, and moſt advantageous Uſes of Wool afforded by his Sheep.

Wool has been conſidered at all Times as a moſt valuable Commodity; and that of our Country is preferable to moſt other upon the Earth. We find the Uſe of Wool known in the earlieſt Periods, and Flocks of Sheep are mentioned in the firſt Ages of Mankind, whether we read of them in Sacred or Profane Hiſtory. Kings and Lawgivers have not been aſhamed to employ themſelves in the Care of them; and therefore the Country Gentleman needs not think their Wool an Article beneath his Dignity. We wiſh to make a Regard to it more univerſal, and ſhall endeavour to render the whole Knowledge of it familiar.

We read in Sacred Hiſtory that the Patriarch ABRAHAM had Flocks, and the ISRAELITES of that early Time all employed themſelves in the Care of them: their Neighbours the MIDIANITES had ſuch Numbers at that early Period, that the ISRAELITES took among the Spoil after their Succeſs againſt them, more than ſix Hundred Thouſand; and drove to their own Lands: and two Hundred and fifty Thouſand were taken from the HAGARITES by the Sons of REUBEN.

The ETHIOPIANS had Sheep alſo; for when ASA conquered a Part of their Country, he carried away Sheep in Abundance: the ARABIANS at the ſame Period had alſo Sheep, for they brought more than ſeven Thouſand Rams at one Time to JEHOSAPHAT; and the MOABITES muſt have bred them alſo in great Quantity, for MESHA, King of that Country, rendered to the King of ISRAEL a hundred Thouſand Lambs, and a hundred Thouſand Rams.

Theſe are Paſſages of Hiſtory delivered in the ſeveral Parts of the Old Teſtament, according to the different Circumſtances that introduced them; and by theſe we find that at this remote Time, much earlier than the utmoſt Extent of any other Hiſtory, that the ISRAELITES had Sheep in great Abundance, and that the MIDIANITES and HAGARITES, the ÆTHIOPIANS and the ARABIANS, and the MOABITES fed them alſo in vaſt Quantities.

Here therefore is an Account of Sheep bred and tended in a Manner all over the Eaſtern Quarter of the World; and we have occaſional Mention alſo of the ſame Creatures making a chief Object of the Care, and a principal Article in the Riches of the AMALEKITES, the PHILISTINES, and the People of DAMASCUS.

Theſe are Countries whoſe Extent and Situation are very well laid down by the Labours of the Learned of later Time, and by this we ſee a great Part of the Quarter of the World, then moſt inhabited, devoted to the Care of this uſeful Animal.

That this Creature was bred not only for its Fleſh, which ſome have very idly pretended, is evident alſo from many Paſſages. The Mention of Wool is made in ſome of theſe, and in others there are Alluſions to the Implements of Weaving, which though they may be applied to either the weaving of Woollen or Linnen Cloth, yet as mention is in the ſame Books made of Wool, and of the Methods of preparing it for the Loom, they muſt be allowed often to refer to this Article.

That the ISRAELITES themſelves fed Sheep for the Wool, may be ſeen by the Tythe exacted on it. In the eighteenth Chapter of DEUTERONOMY, the firſt of the Fleece of the Sheep is declared the Due of the Prieſt: and that other Countries knew its Value in the ſame Manner, is plain from an Inſtance in the Preſent of the MOABITISH King before-named, which is, that the Rams were given with their Wool.

The Staff of GOLIAH's Spear is ſaid to be equal to a Weaver's Beam: the Fullers Field is mentioned in ISAIAH and by the Prophet MALACHI; and EZEKIEL, in the twenty-ſeventh Chapter, calls the People of DAMASCUS Merchants in white Wool.

We have recited theſe Paſſages, which contain the Summary of what is ſaid concerning Flocks of Sheep, their Wool and its Manufacture, in the Scriptures, to ſhew that the ſheering of Sheep, the Uſe of Wool, the manufacturing it into Cloth, and the preparing that Cloth by fulling, were Articles known in the earlieſt Time. It eſtabliſhes the Care of this Animal, and the Uſe of its Fleece, upon a very great Authority of antient Hiſtory: it produces Examples that may animate private Gentlemen to intereſt themſelves in the Care and Management of its Fleece, and Kings and Legiſlative Powers to eſtabliſh and encourage the Manufacture of it. This Attention both of private Perſons of Fortune, and of the Publick Authority and Regard, is greatly want-

wanting at preſent in ENGLAND, for the Advancement of our Woollen Manufactures.

It has been ſaid that GREAT BRITAIN and IRELAND naturally were the Reſources of the reſt of the World for Wool; but this has been a fond Miſtake, and has led the Publick into a Neglect of that Concern, from which it will not be eaſy to recover.

We have ſhewn here that Wool was produced in Abundance, and wrought into Cloth for common Service in the whole Eaſtern Part of the World, before any thing was known of BRITAIN; and we have found by Experience of late Time, that there are many other Countries in EUROPE which may rival us, if we neglect the Care, or our Legiſlature the Encouragement.

It is leading the Huſbandman into a falſe Calm, to make him imagine that the natural Quality of BRITISH Wool is ſo ſuperior to that of other Countries, that he may manage as he will, and it will ſtill have the Preference. Other Nations have been eminent in this Article before BRITAIN was attentive to it. We know not whether this Iſland was peopled at the Time of the earlieſt of the Tranſactions above-named, in which Wool is mentioned ſo importantly; and even long after, when the enterpriſing Genius of the PHÆNICIANS puſhed their Navigation and their Traffick hither, this Commodity was not known amongſt our People.

They traded hither for Tin, which they purchaſed on the SCILLY Iſlands near the Land's End in CORNWAL, then called the CASSITERIDES; and as they came hither on that Account, they took of thoſe early BRITAINS alſo all that they had to offer in Commerce. The ſeveral Articles are named, and Wool is not of the Number. STRABO has committed to Poſterity the different Commodities: they were beſide Tin, the great Article which brought thoſe remote People hither, Lead, Corn, Cattle, Gold and Silver, alſo Dogs of a particular Breed, the old and famous ENGLISH Bull Dogs; and what comes neareſt the preſent Article, Hides. Theſe were the ſeveral Articles furniſhed by the BRITONS, and we ſee they had a Market for whatever was the Produce or Manufacture of their Country, but they never brought Wool to the Traders, though they ſold them Hides. Therefore we ſee that BRITIAN, far from having at all Times ſupplied other Nations with Wool, was a Country that late fell into that Concern; and that there were Manufactures of Woollen in the Eaſtern Countries, and probably in many others, before the Uſe of the Fleece appears to have been known in this Iſland.

This is not wonderful, becauſe the Inhabitants of a great Part of the Kingdom went naked, and thoſe who covered themſelves with any thing uſed the Skins of Beaſts, in a rough and ſavage Manner.

As we have here ſhewn from Sacred Hiſtory, that this was the State of the Caſe, we ſhall, in the ſucceeding Chapter, ſhew it appears alſo in the ſame Light from other Authorities; and from that we ſhall deduce the Leſſon of Induſtry, Care, and Application to the Affair of Wool, for the Service of all concerned, from the meaneſt Farmer to the Sovereign. It appears that other Nations were acquainted with this valuable Commodity before it was known in BRITAIN: they may therefore ſupplant us in all Places, as they have in many, in this Article.

Our Huſbandman has it in his Power to raiſe his Woollen Manufactures, under the Encouragement of the Government, to a greater Perfection than other Nations: this is the Advantage of our Country, let us not ſuppoſe we have more than we have, but knowing the true State and Limits of our Pretenſions, let us uſe every Method to improve them.

CHAP. XXXVI.

Of the early Uſe of Wool in other Countries, according to general Hiſtory.

ALL the old Hiſtorians mention the Care of Flocks, and Value of their Wool; the GREEKS, of all the Periods we know, uſed it for the Purpoſes of Cloathing, and they refer to Times much earlier than their own, as familiar in the ſame Uſe; the famous TYRIAN Purple was employed in dying woollen Cloth; and the early Expedition of the ARGONAUTS to COLCHIS, for what was called the Golden Fleece, however it have been repreſented, was no more than a Voyage of Traffick in Search of this Commodity. The Naturaliſts may ſuppoſe their Voyage was in Search of Gold, and the Adepts pretend that the Secret of the Philoſopher's Stone was couched under this Myſtery: but plain Reaſon, and the moſt authentick Accounts of the Tranſaction, taken in their plaineſt Senſe, ſay nothing more than this; that the People of COLCHIS underſtood the Management of Sheep, and the manufacturing of their Wool, better than any other Nation of that Time; and that JASON, and his Partners, in that Expedition, after encountering many Dangers at Sea, and in their firſt Intercourſe with them, brought back a Quantity of the Wool, and a Number of the Natives to manage the ſame important Article in their Country.

The City of CORINTH became afterwards a general Mart for Wool and woollen Manufactures, and therefore all Commodities in general: and after POMPEY had ſcattered the Pirates, the ſame Article was a very conſiderable Branch of the Commerce carried along the Coaſts of the Mediterranean Sea.

In all theſe Ages, while ſo conſiderable a Traffick was carried on with Wool and woollen Cloths, in the ſeveral Countries we have named, nothing was known of BRITAIN. The Knowledge the PHÆNICIANS had of our Country was loſt; and they had never communicated it to any other People. This Iſland ſubſiſted as a Place ſeparated from the whole World, and unknown to all its Inhabitants; and the Hiſtories, ſuch as they are, that give an Account of BRUTE the TROJAN, and his Deſcendants, their Wars and Victories, mention not a Word of this important Article.

Our Anceſtors, ſomewhat more civilized in thoſe Ages than they had been in the preceding, might, for ought we know, have begun to manufacture

nufacture Wool: that they might do ſo is all that can be alledged, we do not know they did; and of this we are very certain, which is the main Point concerned in this Place, that if they had the Knowledge of it, they ſerved none but themſelves; they had in theſe Ages no Commerce with the reſt of the World: that was ſupplied one Country by another; and we ſee abundantly the Error of thoſe who fancy this Iſland the natural Source of that Commodity.

We not only know that other different Kingdoms at that Time were famous for their Production and Manufacture of Wool, but we are told of ſeveral of them by Name. The ſame accurate and faithful Writers who give an Account of the Commodities of BRITAIN in thoſe early Times, and do not name Wool among them, name that Article as a very valuable and firſt Rate Commodity in reſpect of others. SPAIN is mentioned with great Commendation, in reſpect of the Wool it produced in thoſe early Times, and the Manufactures made from it: inſomuch that ſome attribute the Invention of weaving woollen Cloth to the People of that Nation. Wool was received in the early Times from many Parts of the Euxine; and the Trade of the Baltick was, in a great Meaſure, ſupported by it. The ARMENIANS of the ſame Period purchaſed Wool and woollen Cloths of the TURKS, in Exchange for Horſes. ROME in ſomewhat later Times, received woollen Manufactures from ALEXANDRIA. This all ſtands eſtabliſhed on the beſt Authorities; and is related by all the Authors who have, in any Part of their Works, had Occaſion to mention the Commerce of thoſe early Ages. In all theſe Times BRITAIN continued negligent of this Matter, as is evident from the Silence of all thoſe who mention the woollen Trade of other Nations, among the moſt conſiderable Articles of their Commerce; and ſay nothing of it in reſpect of this, when they treat of the Products of it, and the Traffick carried on by them.

It will be ſeen, in the ſucceeding Part of this Work, how valuable a Part of our natural Advantage we neglected in this Article; and we ſhall, I hope, be cautioned not again to loſe ſo great a Benefit, which ſo many others have, at different Times, taken from us, and will always be ready to take from us again, if our own Aſſiduity, and due Support from the Government do not prevent them.

CHAP. XXXVII.

Of the Wool of different Parts of the World; its Condition and Qualities.

IN the Countries that lie far North, the Wool is generally coarſe, and of little Value.

In ICELAND it is as coarſe as Hair, and in ſmall Quantity. In NORWAY the Wool in general is but poor, though there is ſome tolerably good; that of their natural Sheep is ſhort and coarſe, and ſuch as they bring over from other Places often die in the hard Winters. They work it up into Manufactures at Home, but they are of the pooreſt Kinds: their Cloth is little better than Flannel, and the principal Uſe of it beſide is in a coarſe Kind of knit Stockings, which they not only make for themſelves, but for Exportation to the other Northern Countries, to the Amount of ſixty Thouſand Pairs a Year.

In SWEDEN the Wool is alſo very coarſe, ſhort, and poor: they have been uſed, till of late, to have their woollen Goods from us, but they have ſince encouraged Manufactures ſo far, that they have a coarſe Cloth of their own Fabrick, and to promote the Care of this Branch of their own Trade, a Duty is laid on the ENGLISH.

In MUSCOVY they have Abundance of Sheep, but their Wool is not fine.

In POLAND they have ſome Wool, but it is not excellent.

GERMANY, in many Parts, abounds in Sheep, and their Wool is fine, and the People underſtand very well how to make the beſt Advantage of it.

In the AUSTRIAN NETHERLANDS there is Abundance of fine Wool, and many of the woollen Manufactures have been either invented or improved to a great Height there.

FRANCE is not famous for its Wool, though ſome in the Southern Provinces is very fine, but they import a great deal, and to our great Diſadvantage, from ENGLAND, among other Places; working up our own Produce to ſupply other Markets in our Stead.

SPAIN produces a good Quantity of Wool, and it is the fineſt in the World: we err in ſuppoſing that of our own Country excels all others, this is an Inſtance of the Error, and there are ſeveral others.

PORTUGAL has Wool alſo little inferior to the SPANISH: it is fine and delicate, and fit for the niceſt Works.

ITALY affords ſo much Wool that a great deal is annually exported, and it is very good: the VICENTINE and PARMA in particular are famous for a fine and valuable Kind.

In HUNGARY and TRANSILVANIA there is a great deal of Wool produced, though not of any particular Excellence, ſo that it is leſs fought by Strangers, and in general it is worked up at Home.

In TURKEY they have Abundance of Sheep, and they carry on a conſiderable Traffick in Wool.

In SCOTLAND a great deal of good Wool is produced, though not equal to that of ENGLAND. In GALLWAY, TWEDALE, and more North, they have what is very fine, and they underſtand it very well. They had the Art of making Broad Cloth in great Perfection before the Union. The GLASGOW Plads exceed all other Manufactures of that Kind; and they have many other very good ones. There is a Method in the dying the red Part of theſe Manufactures, which the SCOTS have the Addreſs to keep to themſelves, and which keeps them the Pre-eminence in that Manufacture, though all the Arts poſſible have been uſed by our People to diſcover or purchaſe the Secret. The SCOTS are more honeſt than our People of the ſame Rank; it would not have been eaſy to have kept a Secret of that Importance in ENGLAND, which was neceſſarily entruſted to ſo many People.

In the East they at present less regard the Produce of this Commodity; because their principal Manufacture are in Silks and Cottons, but there is a great deal of very fine Wool in ASIA, SYRIA, and PERSIA. They have a particular Breed of Sheep in this last-named Country, whose Wool is long and greyish, and they make certain peculiar Manufactures of it, and those much esteemed.

In CHINA and the EAST-INDIES the Produce of Wool is so great, that they shear their Sheep three Times a Year: and in AMERICA they feed Abundance of Sheep, whose Wool, in many Parts, is little inferior to that of our own Country.

CHAP. XXXVIII.

Of the Methods of managing Wool in different Parts of EUROPE.

THE FRENCH, who very well know where the best Wool is to be had, get what they can from ENGLAND, not a little from SPAIN, and purchase it wherever good is to be had in other Places. The foreign, as well as their own, they divide into separate Parcels, according to the Degrees of Goodness, before they work it up or dispose of it. Most other Countries have the same Practice, and from their dividing it into three Kinds this is called the Triage of Wool.

These three Kinds are called, in all the modern Languages, the first, the second, the third Kind of Wools. And when the Fleece is sold entire, there is usually made a Distinction, according to its Quality, into a first or a second Kind: the fine and the coarse being distinguished by these Names.

The Proprietor has his Choice to sell his Wool in the Gross, as it is shorn, or to clean and separate it; and in general the best Method is to manage every Commodity as well, and work it as far as the Knowledge or Convenience of the Husbandman will permit; for those who buy Things in the Rough, as they call it, always make themselves large Allowances for Waste and Labour in the working. In many Articles the Difference between selling the Produce in this rough Way, and selling it wrought, so far as the Farmer can conveniently do it, is Thirty per Cent.

The Wool of SPAIN is principally from CASTILE, ARRAGON, and NAVARRE, and of these the first is generally the finest. It makes an admirable Mixture with our ENGLISH Wools. Those of FRANCE are, by all Acknowledgement, greatly inferior to ours; yet they by a proper Mixture of the SPANISH, and a good Fabrick, have produced Cloths very little inferior to our own, when we have kept our Wool entirely from them. Our People should in this learn from their Neighbour's Policy.

In SPAIN, where they are very choice of their fine Wool, they have five different Ways of selling it; and the ENGLISH Farmer should observe the Difference for his own Information. They sell it, sometimes singly on the Sheep's Back; secondly, Coarse as shorn; thirdly, Washed and cleaned; fourthly, Wash'd, cleaned, and triaged; that is, separated into the finest, second, and coarser Kind; and fifthly, On the Sheep's Back at a general Price, to pay for one Pile what other Piles of the same Quality shall be sold for. They generally find the fourth Way the best for the Seller, and the fifth the best for the Buyer. 'Twas once a Custom in ENGLAND to sell the Wool in this Way, but our Farmers are grown wiser, and we hope they will continue to be so.

The Difference in Quantity between the Wool as it is shorn, and when washed and cleaned, is about one half: sometimes the Waste is a little less, sometimes a little more, but usually about this. The second Cleaning, which prepares them absolutely for Cloth, reduces them near a fifth; and this is the whole Waste in general Terms.

This will inform the Farmer upon what general Conditions he may set the Price of his Wool, if he chuse to part with it rough, but it will in this, and all other Articles, always be his Interest to work them as far as he can himself: this is so universal, that he should understand it as repeated under every Article.

Upon the whole, having looked into the Produce of the Wool of different Countries, we shall do well to consider the Nature of their Pasturage, and other accidental Things of every Kind, that the Farmer may see not only where the best Wool is produced, but form some rational Guess to what the Excellence is owing.

In general two Things contribute to the Fineness of Wool, the Sweetness of the Pasture and the Cleanliness of keeping.

In SPAIN, where the Wool is excellent, the Grounds are in a Manner barren, in Comparison of those in many other Countries, and in many of the Northern Nations we have mentioned, as producing indifferent Wool, the Meadows are covered with a very rich Grass: but then the little Grass of SPAIN is sweet, and this abundant Quantity of the Northern Kingdoms is harsh and sour. A coarse Grass makes a coarse Wool; and to this we may attribute the ill Success of those several Schemes which have been practised, of carrying the Sheep of Wool Countries into others not famous for that Produce; the Kind is not of so much Importance in this Matter, as the Nourishment; and the same Sheep in a sweet Pasture will yield the finest Wool, that will afford but indifferent on a coarser Grass.

The practical Rule to be drawn from this is, that the Farmer who has a Mind to raise the Credit and Price of his Wool, should first chuse a proper Breed, which we have sufficiently directed under the Article of Sheep, and then feed them principally, if not entirely, upon his sweet high Pasture Grounds.

Cleanlyness is the next Article, and this follows the other in Course, for the Sheep on Downs are always much cleaner than those in low Grounds. The FRENCH cannot be so careful in this Respect as we may, because the Fear of Wolves renders it necessary for them to house their Sheep in Winter; and in this Case there is no Possibility of their living so sweet and clean, as when they went on in an open Pasture, and touch

touch nothing but the Grass washed with the Dews of Heaven.

Our covered Fold for raising Manure from the Dung and Urine of Sheep, will be little Disadvantage to their Wool, if the Earth thrown into it be of a sandy or dry loamy Kind, and none answers that Purpose better.

CHAP. XXXIX.

Of the Origin of the Woollen Trade of ENGLAND.

WE have seen how late, in Comparison of other Nations, the People of BRITAIN fell into the Care of Wool, and the manufactureing of it; and we shall find, upon farther Enquiry, that by all we have remaining on the Subject, the Progress made in it was at first very slow.

This is the more to be lamented because we have, and always had, the finest Pastures in the World. The improved State of Husbandry has, from time to time, brought in new Advantages to tilled Land, and none more than the latest; but at all Times the Pasturage must have had its Character of Excellence and Superiority, nay probably in the Times when Agriculture was least improved, that Part of our Produce was best, because then the best Lands lay for it. Grass is a Product of Nature, in which she needs no Assistance from the Hand of the Labourer, or Genius of the Husbandman: her own Hand plants the Growth, and the Rains of Heaven are all it needs for bringing it to Perfection.

There never was any Time therefore in which this Country wanted the Means of feeding Sheep, and consequently there has been no Time when it might not have produced Wool in Abundance: we have the same Advantage over all other Countries in the World, at this Time, in respect of our Pastures: and let the Husbandman well regard it. Let him remember how many Ages other Nations, as we have shewn him in the preceding Chapters, ran away with the Profit of this great Commodity, before his Ancestors in this Island thought of interesting themselves in its Concern; and let him recollect later Instances in which they have, and in which, I am sorry to say, they do rival us through our Neglect: what Advantage they had before the BRITONS entered on the Trade they may have again, if it be neglected on one Hand, or restrained by Authority on the other: and let these Considerations have their Effect in the stirring up all Ranks to promote and patronize it.

If we would know by what slow Degrees the Care of Wool, and the Profits rising from it, became known in ENGLAND, we must refer to those Records in which it has been occasionally named, or in which any thing concerning Sheep is to be found; for we are not to expect that we shall, in any early Time, find an Account of a Trade established on this Article.

We have shewn that the Generality of our Ancestors, in early Time, went naked, and that Skins were the Covering of the rest; in the Time of the ROMANS Commerce became more established in this Island; and LONDON was a Place of great Traffick: but Wool was not of the Number of the Articles in which either our own People, or the ROMANS settled among them, traded.

One of the earliest Notices we have of Sheep in BRITAIN, considered with respect of their Value is found in STILLINGFLEET *, who tells us, That between the Years seven Hundred and twelve, and seven Hundred and twenty-seven, were made certain Laws of King INA, and in those a Value or Price was set upon the Sheep Kind. The Price of an Ewe and her Lamb together, till a Fortnight after EASTER, is there set down at One Shilling. The Value of Money was then very different from what it is now, but this, with all the Allowances that can be made on that Head, is but a very poor Price.

* *Chronicon Pretiosum*, p. 20.

We may learn by it that in King INA's Time the Care of Sheep was grown to some Concern in the Island; and there are other Passages of the same Period, that shew Wool was an Article comprised in the Purchase of these Creatures; but by all we learn on this Head, the Art of working it was but at a poor Height; nor was any of it exported either wrought or raw.

ALFRED, a Name famous for Military Atchievements, and also for the Care of Arts and Commerce, took no small Pains to improve this Manufacture; but they did not much succeed; 'twas in the Year 885, he set in earnest about this great Work, but Wolves were too numerous in the Island to let Sheep be kept in Safety.

The Consequences of the Encouragement this Sovereign gave to the raising these Animals, was seen in the succeeding Years; for in 918, EDWARD, who had married the Daughter of a Country Gentleman, distinguished by the Regard he had shewn to this great Concern, and thence called by those who little understood what they read in earlier Writers, a Shepherd, had his own Daughters instructed in the Art of carding, spinning, and manufacturing Wool.

This double Patronage bestowed by EDWARD, the Countenance he gave to one who employed himself in breeding Sheep, and the Example he set in making his Daughters work the Wool, was of so much Assistance to the Manufacture, that the Pasturage of the Southern Countries became mostly occupied in feeding Sheep, and every one, fond of recommending himself to the Royal Favour, became a Shepherd, or at least employed his Attention greatly on that Article.

The Wolves were for some time the principal Obstacle to the Progress of this great Undertaking; but after many Struggles with this Inconvenience, EDGAR, about the Year 961. setting a Price upon their Heads, and by every other Means encouraging their Destruction, three or four Years did the Business: there was not in that Time a Wolf left in the Kingdom.

The Value of the Sheep rose in Proportion to the Number propagated and preserved: for with the Encrease in the Quantity of Wool, the Number of Manufacturers encreased, and the Demand for it enlarged. The same Author who tells us that in 720. in the Time of INA, an Ewe and her Lamb together, were valued only at a

Shilling

Shilling in the beſt Seaſon, ſhews us that in 1000. under the Reign of ETHELRED, a Sheep alone was worth a Shilling, without any Reſtraint of Seaſon †. This Shilling was SAXON Money.

† *Chron. Pretioſum*, p. 81.

This ſhews that the Value of Sheep roſe, but it alſo ſhews that it was but ſlowly. No Exportation of Wool, or woollen Cloth, is yet heard of in the Market at Home; and People principally wrought up the Produce for the Service of their own Families.

A Hundred Years after we find by an accidental Paſſage, that the Value of Sheep was rather decreaſed than encreaſed, ſo that we may ſee the working up the Wool did not thrive very faſt. The black Book which contained the Taxation of every Man, toward the Support of the King's Houſhald, there mentions Money as an Equivalent for Cattle, and the Sum on each Article is ſtated. Ten Years before this Time we find, that if a Sheep was loſt the Damage was eſtimated at Five-pence, but on this Occaſion the Price laid upon him who choſe to pay his Tax in Money, inſtead of Cattle, was only Four-pence in the Place of One Sheep.

Purſuing this Subject in the old Records, we find the Sheep more numerous in all the ſucceeding Reigns, and we ſee their Value encreaſing conſtantly with their Number. In the Time of HENRY the Firſt, about the Year one Thouſand one Hundred and Twenty, forty Sheep were valued at One Pound.

In one Thouſand one Hundred and Eighty-five an antient Record tells us, that by the Cuſtom of BELESHAL, the Tenants of SHERBORN were, on certain Occaſions, to make their Acknowledgement by delivering a Ram, but if they choſe to pay in Money, the Price was fixed at Eight-pence.

The Reader is not to imagine that this Price eſtabliſhed upon Sheep, had Regard to their Fleſh for Food, without Reſpect to the Wool: it is true that all Hiſtorians are ſilent upon the Progreſs of that Commodity and its Manufactures, but we have, a few Years thereafter, a memorable Inſtance of the Regard ſhewn to it as a National Commodity.

RICHARD the Firſt, in the Year one Thouſand one Hundred Ninety-three, returning from the Holy War, was taken Priſoner by the Duke of AUSTRIA. A vaſt Ranſom was required, and toward raiſing it one Year's Wool was demanded from two of our Abbeys. This is a Paſſage recorded by RAPIN †, and all the common Hiſtorians, and is ſupported on the beſt Authorities: and this ſhews, though we have not had any regular Account tranſmitted to us of the Progreſs of this Article of Commerce, that all the Time the Price of Sheep was encreaſing the Value of Wool was riſing, and that this was the principal Cauſe of their Encreaſe in Value: and we find that at this Period Wool was become the firſt Commodity of the Iſland: the Thing next named in Purchaſes to Money.

† *Rapin's Hiſt. of Eng. v. 1. p. 254.*

Till this Time we hear, as I have before-obſerved, nothing of any Uſe of Wool, except for our Home Conſumption, but this Tranſaction ſeems to have opened the Eyes of the neighbouring Nations. Having received ENGLISH Wool in Payment they found it excellent, and they began to think of it as a Purchaſe. The Paſtures of BRITAIN now ſhewed the World their Excellence for the feeding this uſeful Animal, and the Huſbandmen began to acquire a Reputation for its Management. Exportation of Wool became a common Practice, and the Article from this Time grew ſo important, that it was the great Source on all Emergencies. It was the Land Tax and the Malt Bill of thoſe early Periods.

The firſt Notice of its Exportation is in the Year one Thouſand one Hundred and Ninety-eight, only five Years from the Time of RICHARD's Ranſom.

In this Year we find, in MADDOX's Hiſtory of the Exchequer, that GERVASE DE ALDERMANBURY ‡, rendering an Account of the Chamberlainſhip of LONDON, gives in this ſingular and important Article: Fines from Merchants for Permiſſion to export Wool and Leather Twenty-three Pounds twelve Shillings.

‡ *Maddock's Hiſt. of the Exchequer*, p. 532.

At the ſame Time that Quantities of Wool began to be exported, the manufacturing of it at Home encreaſed. The ſame Exchequer Account gives a Liſt of ſeveral Sums by the Sale of Wool at Home; of twenty Pounds from one Perſon, and of two Hundred and Twenty-five Marks from the Seizure of a Quantity that was attempted to be ſmuggled out of the Kingdom, or exported without paying the Fine for Leave.

This is an Article recorded in the ſame Author, and it tends very happily to the ſhewing the real Price of Wool in ENGLAND at that Time.

The Quantity of Wool ſeized on this Occaſion was forty-five Sacks. Each Sack we find was valued at five Marks, and each Sack contained twenty-ſix Stone of Wool. This ſettles the Price of Wool in ENGLAND, in the latter Part of the Reign of RICHARD the Firſt, at little more than Two and Six-pence a Stone. This Two and Six-pence was, at that Time, one Eighth of a Pound Silver, and was equal to about three Times that Quantity or Weight of Silver now; that is, to ſeven Shillings and Six-pence.

The Reader will, we hope, not blame us for deſcending to Particulars in a Point of this Curioſity and Importance. We ſhall endeavour to trace the Hiſtory of this Commodity from the beſt Records of earlier Time, and ſhew him its Advances and Decline under the different Encouragements or Oppreſſions of its Manufacture.

About thirty Years after the ENGLISH found the Way of ſerving their Neighbours with our Wool, we improved ſo far in our own Manufactures of it, as to get into the Art of dying. At firſt Wool was only wrought up in a coarſe plain Way for the Cloathing of the Farmer and his Family: by Degrees thoſe who beſt underſtood the working of it up, brought what they had to ſpare from the Service of their Family to Market; but all this Time the Wool was only wrought up as it was furniſhed by the Sheep, and all Cloth was of the ſame Colour.

They found that, thoſe who imported Wool and woollen Cloth from us, in its natural Colour, dy'd it at Home; and they ſoon learned the Art of doing the ſame here. We read in the Sta-

tute Book, that in the ninth Year of HENRY the Third, dy'd Cloth was limited by a certain Law, as to its Quantity and Measure.

Our Wars with FRANCE, and other Difficulties, broke in upon the Progress of our National Trade in 1242, the Persons and Effects of the ENGLISH Merchants in FRANCE, and those of the FRENCH Merchants in ENGLAND, were seized in Consequence of Hostilities between the two Nations; and in 1275. all Commerce was prohibited between ENGLAND and FLANDERS, upon a like Account; but upon this Occasion we find an Instance of the great Height to which the Wool Trade of ENGLAND was arrived at that Time, for a few FLEMISH Merchants were permitted to carry over a Quantity of ENGLISH Wool with them, paying the King for the Permission. This Quantity was no less than a Thousand and Sixty-eight Sacks, and the Price for Leave of Exportation was ten Shillings a Sack. We see by this how swift a Progress the Commerce of the Kingdom, in this Article, had made, when the Husbandmen understood the Value of the Commodity; and the Legislature encouraged its Manufacture.

We find by the Accounts here given, how little Historians and others have considered this important Article. Those who speak of the Manufacture of Broad Cloths in ENGLAND, follow one another in placing the Time of their being first made at the Year 1331. We see from this Circumstance, countenanced by the Statute Book, an unerring Guide, that they were not only made but dy'd so early as in the Year 1220. one Hundred and Eleven Years before that Time; and probably the Origin of the Manufacture was much earlier than that.

The Quantity of Wool our Country produced soon after, is to be guessed from the vast Exportation we have named under those FLEMISH Merchants; and this as recorded punctually by RYMER *.

* *Rymer*, vol 2 p. 50.

In 1284. foreign Merchants were permitted to establish themselves in the Kingdom, for the Encouragement of the woollen Manufactures. They had till this Time been obliged to lodge in the Houses of our own People, and could not trade otherwise than by making their Landlords their Brokers; but now they were permitted to traffick in their own Names; and the Privilege granted to them was of the utmost Benefit to the Trade.

In 1291. SANDWICH in KENT was made the general Market, by an Act of EDWARD the First, and so vastly did the Trade encrease, and the Manufacture flourish, that but five Years after this the Custom upon it was raised from twenty to forty Shillings a Bag; and the Traffick was able to support it.

This Demand was indeed repealed, but not because it would have ruined the Trade, but because it was made by the King's sole Power. That was a Stroke too arbitrary for those Days of virtuous Liberty: the Merchants exclaimed against it, and they obtained a Release from the absolute Exaction, the additional Duty being charged by this Act upon them with such Limitations, that it was in a Manner dependent on their Pleasure; and soon afterwards it was left to the Determination of Parliament.

A few Years after this we find the Traffick for Wool and woollen Manufactures very flourishing in LONDON; and several of the Sea Port Towns: the King's Duty upon exported Wool was established upon it according to the Weight; and the Scales for weighing it in all Parts were made by those in LONDON, and delivered in a solemn Manner by the Lord Mayor into the Exchequer, to be sent to their respective Places.

In 1297. the Wars with FRANCE demanding a great Supply: the woollen Trade was so flourishing that Recourse was had to it. The Parliament granted for two or three Years forty Shillings a Sack upon Wool. This was the Exaction that had occasioned so much Disturbance at first; but now it was legally established and regularly paid. The King promised never to demand more than the old Duty, without Consent of Parliament; and the woollen Trade flourished under this large Drawback, and the Disadvantages of a War together.

These were Times of virtuous Government. The King was thankful to his Subjects for so large a Supply, and he was happy to find that the woollen Trade could bear it: but he demanded it no longer than it was required by the Exigences of the State, on Account of which it was raised. He called a Parliament, and of his own free Accord gave up the additional Duty, publishing a Proclamation that no more than the old Sum should any where be demanded.

The Price of Sheep now naturally rose with the Value of their Wool, but still the Number made some Alteration. We read in THORN † of three Shillings apiece being given for three Hundred Sheep; but it was at an Installation Feast, 1309. The current Price about that Time was much less, as we find in the Acts of the Common Council of LONDON, and in DUGDALE.

† *Decem Scriptores.*

In the Year 1315. we find the Price of Sheep established in such a Manner, as to give us a fair Insight into the Value of Wool at that Period. The Sheep, if delivered shorn, was fixed at Fourteen-pence; if unshorn at Twenty-pence ‡, but we must not extend this Consideration farther than to the Value of the Wool, for it was a Time of Famine.

‡ *Stillingfleet's Cirac.* p. 72.

From this Period the woollen Trade became an Object more than ever of the publick Concern. Persons of all Nations who could improve the Manufacture of Broad Cloth, were encouraged to come over; and among Numbers brought under great Encouragements from FLANDERS, BRABANT, and ZEALAND; there were some so worthy of the Advantages they received, that they soon set the Trade upon a most respectable Footing Abroad, and upon the most profitable Foundation at Home.

In Consequence of the greater and more profitable Traffick in this Article, the Price rose; and the more Assistances were drawn from it for the State; in EDWARD the Third's Reign, toward the End, we read of Subsidy after Subsidy on Wool: and in RICHARD the Second's Reign more Subsidies were demanded; the Traders complained, and the Matter being candidly examined,

it

it appeared that though they were not wholly without Reaſon of Complaint, yet the Trade could bear additional Loads, and that they might raiſe Fortunes.

In the Reign of HENRY the Fourth the Sanction of Parliament granted to the King, for a limited Time, a Subſidy of fifty Shillings upon every Sack of Wool belonging to the Natives, and four Pounds on thoſe of Strangers exported; and ſuch was the Produce of Wool in BRITAIN at that Period, and ſuch the foreign Demand for it, that the Quantity exported was not leſs than a Hundred and thirty Thouſand Packs in a Year: and in RICHARD the Second's Time the Subſidy had amounted to a Hundred and ſixty Thouſand Pounds. This is related by PRYN, and the other Hiſtorians, and is ſupported on the beſt Authorities.

The ſame Subſidy that had been granted to HENRY the Fourth, was allowed for four Years in HENRY the Fifth's Time.

In the Reign of HENRY the Sixth we find thirty-three Shillings and Four-pence a Sack allowed to the King on the Natives Property in this Article; and forty-three Shillings and Four-pence on that of Strangers. The woollen Trade encreaſed under all this Demand; and NORWICH about this Time became eminent in it.

In the former Reigns the large Subſidies on Wool had been granted only for two, three, or four Years, in Time of Neceſſity; but in the Reign of EDWARD the Fourth, the Charge of thirty-three Shillings and Four-pence on the Wool of the Natives, and of three Pound Six and Eight-pence on that of Strangers, even the naturalized, was granted to him for Life.

Even this proved no Check to the Traffick. Encloſures became more frequent; the Land was more improved, the Management of the Cattle and their Wool was better underſtood; and ENGLAND carried the Praiſe for this Article before all other Nations.

In the Reign of RICHARD the Third, though the Traffick was encumbered with large Subſidies, it encreaſed continually. In the ſucceeding Reign of HENRY the Seventh, the greateſt Regard was ſhewn to Trade in every Article, and in none more than this. The Exportation of Wool was limitted, and the Manufacture of Cloths encreaſed accordingly.

In HENRY the Eighth's Reign the Produce of Wool was greater than at any Time before; and its Price encreaſed with the Quantity; ſuch was the Demand for it Abroad, and ſuch the Conſumption of it at Home. Farmers were laid under certain Limitations, as to the Number of Sheep they were allowed to keep; but theſe were very extenſive ones, and we may ſee by the Account preſerved of this Tranſaction, and of the Price of Things at that Time, to what an Advance the Care of that Animal, and the Price of its Fleſh and Wool, had riſen.

No one was to have more than two Thouſand, but this with many Exceptions. The Statute, by way of Reaſon, recites "The advanced Price of "all the Native Commodities in the Kingdom. "That ſome Perſons had at that Time vaſt Num-"bers of Sheep, which for Victual had riſen in "Price from two Shillings and Four-pence, or at "the moſt three Shillings, to ſix Shillings, or five "Shillings, or four Shillings at the leaſt; and "that a Stone of Cloathing, heretofore in ſome "Shires accuſtomed to be ſold for Eighteen-"pence or Twenty-pence, had riſen to four Shil-"lings, or three Shillings and Four-pence at "leaſt. In others, where it had been ſold for "two Shillings and Four-pence, or two Shillings "and Eight-pence, or three Shillings at the moſt, "it was then ſold for five Shillings or four Shil-"lings and Eight-pence the leaſt."

If we look back to the Prices of Wool in the thirteenth and fourteenth of EDWARD the Third, which was near two Hundred Years before, the loweſt, viz. the Wools of CUMBERLAND and WESTMORELAND, were ſold for above two Shillings per Stone, excluſive of the Duty, which was ſomething more than one Shilling and Six-pence per Stone; and thoſe of SALOP, at better than four Shillings and Ten-pence per Stone, in like Manner. So that in Fact, there ſeems to have been at this Time, no Advance in the Price of Wool from the Period juſt mentioned: but very much the contrary, conſidering that the Shilling was then two Hundred and Sixty-four Grains; and at this Time, but one Hundred and eighteen. Nor was it any Advance from the cheap Price of which H. KNYGTON ſpeaks, becauſe the Shilling was then two Hundred and thirteen Grains. Much leſs was Wool dearer at this Time, than in the fourth of HENRY VI. The Price being then not only nearly equal to the higheſt Rate mentioned in this Act, but the Shilling then, at the loweſt, contained Twenty-four Grains more than at the Time of the Act; and therefore we are to ſuppoſe the Complaint then made concerning the Dearneſs of Wool, to have had reſpect to ſome intermediate later Times, in which the Price of Wool does not now appear; and which was probably occaſioned by the Monopolizations of the Merchants of the Staple, and the Manufacturers.

As to the Price of Victual, it will not be amiſs to inſert here a little Piece of Hiſtory, which Biſhop FLEETWOOD takes from Mr. STOW, in the Year one Thouſand five Hundred and Thirty-three. It was that Year enacted, "That Butchers ſhould ſell their Beef and "Mutton by Weight: Beef for a Half-penny "the Pound; and Mutton for three Farthings: "which being deviſed for the great Commo-"dity of the Realm, as it was thought, proved "far otherwiſe. For at that Time, i. e. one "Thouſand five Hundred and Thirty-three, "fat Oxen were ſold for Twenty-ſix Shillings "and Eight-pence, fat Weathers for three Shil-"lings and Four-pence, fat Calves for the like "Price; and a fat Lamb for Twelve-pence. "The Butchers ſold Penny Pieces of Beef, "for the Relief of the Poor; every Piece two "Pounds and a half, ſometimes three Pounds. "And thirteen, ſometimes fourteen of theſe "Pieces for Twelve-pence. Mutton Eight-"pence the Quarter, and a Hundred Weight "of Beef for four Shillings and Eight-pence. "What Price it has grown to ſince needs not "be ſet down. At this Time alſo, and not be-"fore, were foreign Butchers permitted to ſell "their Fleſh in LEADEN-HALL Market of "LONDON." I ſuppoſe by Foreign Butchers,

he means such as lived not, or had not served their Apprenticeship in LONDON.

CHAP. XL.

Of the Wool Trade from the Time of HENRY *the Eighth.*

WE have seen what a prodigious Advance the Wool of ENGLAND made in the several preceding Reigns, and we shall find it in this continue encreasing.

Husbandry had been in early Times but very little understood in ENGLAND, but the Regard to this Commodity, the Demand for which was so considerable, and the Price so large, gave a Spirit to the People concerned in it at that Time, which we wish had been continued to the present.

In EDWARD the Sixth's Reign we seem to have had Farmers in ENGLAND, who understood the Management of Pasture Ground so well, that it were happy if Books had been written on the Subject, which had perpetuated their Improvements. The great Benefit of Enclosures was a little before understood fully, and they encreased in the Reign of EDWARD the Sixth. The Care of the Pasturage grew with the Number of Enclosures, and the thriving of Sheep, and the Price of Wool, with it. That Commodity sold in this Reign dearer than in any of the preceding. Statutes were made from time to time, to encourage the Manufacture of Cloths, and Marts were established by Authority in different Places.

In the Reign of PHILIP and MARY the Subsidies granted to EDWARD the Sixth were continued, only with a Limitation in Favour of naturalised Strangers, or such as should be naturalised. Many good Statutes were enacted in Favour of the woollen Manufacture in this Reign; and it throve greatly under the prudent Regulations that were established, and extended itself to many Parts of the Kingdom.

In Queen ELIZABETH's Time a Subsidy was granted for Life on this Article, included in Tunage and Poundage: many good Statutes were made in that Reign, and Numbers of the FRENCH and FLEMISH engaged in the Cloth Trade, leaving their native Country becaufe of Perfecution, brought over their Secrets, and encreased our Credit. In this Reign Wool unmanufactured rose from its former Price, which might be called Thirteen and Four-pence to two and twenty Shillings a Tod.

We may safely establish the Period from the End of EDWARD the Sixth's Reign, to the End of Queen ELIZABETH's, as the most flourishing of all Times for the Wool Trade of ENGLAND. It has never risen much higher since, and it has very often been much lower; in general, considerably below that Standard.

Yet even in that Time we were far from supplying all the World, or all EUROPE, with Cloth; for there were many other Countries very eminent in the same Manufacture: this therefore, as we have shewn before, is an imaginary Notion; and it is altogether erroneous to suppose we ever did, or ever shall have that vast Trade to ourselves. It is enough if we can get the Superiority in the Manufactures, which doubtless we may; and we may be very proud of our Success, if we can yearly bring in such Sums as it then raised; which were, moderately speaking, near three Millions a Year.

In the Time of JAMES the First Wool afforded Subsidies, and that largely. New Regulations were made, and Statutes enacted. Monopolies and Oppressions were introduced, but the Clamours of the People got the better of them: the Desire of growing rich too fast became however general among the woollen Dealers, and hurt the Trade extreamly: Abuses were committed in the making Cloth; and our Credit in Consequence declined, during this Reign, in foreign Markets. Proclamations were published to prevent the Exportation of Wool, and Search was made into the Nature of the Abuses; but in vain. The Manufacture dwindled, and the Price of Wool fell from Thirty-three to eighteen Shillings a Tod.

The first Years of King CHARLES the First's Reign, promised the Revival of the woollen Trade; but the Disputes succeeding reduced it lower than ever. Proclamations now took the Place of Statutes; and the Exportation of Wool was forbid by several of them.

In 1640. Wool was advanced again to Twenty-four Shillings the Tod.

In 1671. many Attempts were made to restore these Manufactures to their former Glory. The bad Consequences of suffering our Wool to be exported unmanufactured were shewn; and Propositions made for gaining several hundred Thousand Pounds a Year, by throwing that Trade into a better Method: but these were Times in which Men better knew what should be done, than how to do it.

In 1685. the FRENCH began to supply foreign Markets with what they called ENGLISH Cloths. These had been made of ENGLISH Wool, and while that was, in despite of all Remonstrances, suffered to be exported; and so many Disadvantages laid on our Manufactures at Home, it was no Wonder they could under-sell us in the same Articles. The publick Attention was waked by this, the Exportation of Wool was absolutely prohibited, and great Encouragements were given for the Produce of Wool, and for the working it here into marketable Manufactures. This raised the Spirit of the People, and the Advantage was soon seen: happy had it been if the Measures so projected had been as properly continued.

When Wool, except in woollen Manufactures, was prohibited Exportation from ENGLAND, the FRENCH, and other neighbouring Countries, got it from IRELAND; and this was soon seen, and its Disadvantages; and Laws were enacted against it.

In 1703. the woollen Manufactures began to flourish again in ENGLAND: a Treaty was soon after made with PORTUGAL, very advantageous to them; and there was the Appearance of their again making great Progress. The FRENCH droop'd in this Article, for some Time after they were deprived of our Wool; but they found the Way afterwards to rival us, with what they produced

duced at Home, or got from elſewhere; and the Manufacturers with us ſaw that there was no Way but Integrity in their Dealings, and a Care of the Trade that could give them the Preference.

Theſe great Articles of the Trader's Character, were not found: integrity was wanting in ſome, and Knowledge or Attention in others, and for ſeveral ſucceeding Years Things, in this Reſpect, went worſe and worſe: the Neglect of thoſe moſt concerned let FRANCE get our Wool again in great Quantity, and our own Manufacturers drooped in proportion: for this has been found at all Times, that although the FRENCH can carry on their Traffick in this Article without us, yet they always ſucceed beſt when they have moſt from us; and we droop in proportion.

To cloſe this important Conſideration we muſt obſerve, that on two Things depend the flouriſhing State of the BRITISH woollen Manufacture: on the Care of the Huſbandman in the proper Management of his Sheep and their Produce; and on the preventing its Exportation when we have it in the proper Condition. We have laid this ſhort Hiſtory of the Riſe and Progreſs of the woollen Manufacture before the Huſbandman, to ſpirit him up in this great national Concern; and to ſhew him that they are idle Declaimers who tell him ENGLAND always muſt be the Country for the beſt or largeſt Quantities of Wool; that he may know how much it is neceſſary to exert himſelf in a Concern on which the Welfare of his Country, and his own Advantage ſo greatly depend.

Having given him this full Detail of the State of the Trade, we ſhall proceed to the Practical Part; and acquaint him how he is to manage his Wool to the beſt Advantage. We ſhall not enter upon a nice Detail of the Manufacturer's Profeſſion, but only lay down the plaineſt and moſt profitable Rules for ſo much of the Management of Wool, as concerns the Farmer: that is, the preparing the great Part for Sale; and the working up the reſt at Home, for the Service of his Family.

CHAP. XLI.

Of cleaning, carding, and greaſing of Wool.

WE have, in its proper Place, laid down all the Rules needful to the Huſbandman for the Choice, breeding, and feeding of his Sheep, and have at large acquainted him with all that is needful to be done in the great and important Article of Shearing.

We will ſuppoſe therefore that he has got his Wool from the Backs of his Flock, and proceed to tell him what he is to do with it. The Miſtreſs of the Houſe naturally undertakes the Office of preparing the Wool for her Family Clothing: the Huſbandman is therefore to deliver to her ſuch a Quantity as will anſwer this Purpoſe, rough from the Hands of the Shearers.

The firſt Thing to be done with this is to open it with a Pair of Shears, and cut away all the foul Pieces, Knots, and Lumps of whatever Kind. Theſe muſt be laid by for meaner Purpoſes, and the reſt thus cleanſed muſt be broke and divided very carefully between the Hands, that there may be none of it left matted together.

When it is all thus clean, looſe, and fine, it is ready for carding: but as ſome will be required white, and other Part coloured, it is to be ſeparated for that Purpoſe. Such as is for Colours muſt be divided into different Parcels, according to the intended Dyes; and the uſual Way is to keep each Parcel in a ſeparate Bag of netting, with the Weight marked upon it. Theſe are then to be ſent to the Dyers, and the Owner will be ſure, by this Precaution of the weighing and marking, not to be deceived.

The white Wool as it is, and the other when dyed, are to be wrought juſt in the ſame Manner.

The firſt Operation is carding: and the Intent of this is to mix and blend equally every Part; to tear it open perfectly; and to diſcover and ſeparate any Knots or Lumps, which may have been ſo ſmall that they were not obſerved in the breaking of the Wool by Hand.

This carding ſhould be very carefully performed by Means of a Pair of Stock Cards well faſtened to a Form. The whole Quantity is to be over and over combed and carded on theſe, and the leaſt Knot that is found is to be ſeparated.

When the Wool has gone through this careful Management, it is to be greaſed. This is done by Means of Oil; and the common Kind of Oil uſed for the Purpoſe is the Rape Oil made from Coleſeed, which we have before named in its Place.

The Wool is to be ſpread evenly upon a large flat Bed, and the Rape Oil is to be ſprinkled on it carefully with the Hand, till there is enough put on to wet the whole in every Part. Then the Wool is to be moulded and worked about with the Hand, that every Thread of it may be moiſtened. The beſt Way is to turn the whole once, or oftener, as the Oil is ſprinkled upon it; and by that Means it works in the eaſier. Every Part muſt have its Share, that is the great Concern. Yet in the Care of this there muſt be Regard had to the Quantity of Oil employed: it would be eaſy to wet the Wool, by pouring on a great deal of Oil at once, but this would ſpoil it: the Art conſiſts in having every Part really wetted, and yet none too much. This is the Reaſon of ſprinkling the Oil on ſoftly, and turning the Wool often while it is doing; and in this conſiſts the Art of greaſing, as it ſhould be: it is of the greateſt Conſequence, to moiſten the Wool well with a little Oil, for on this depends the Perfection of the Web. If too much be uſed the Thread will not draw, but will fall into very ſmall Pieces.

There is no better Way of being ſure of finiſhing this right, than the trying it at Times as it is doing. When the Wool is greaſed it is fit for ſpinning: therefore nothing will be ſo proper as to have a Wheel by, and try it from time to time. A little Oil ſhould be worked in at firſt, and then the Wool tried on this Wheel: if it draws dry and breaks, then a little more Oil is to be uſed; for the Uſe of this is to keep it moiſt and ſupple, and to make it hang together: this Purpoſe it excellently anſwers when a ſmall

Quantity of it is well mixed with the Mass; but as we have observed already, when too much is used, and it is put to the Wool in a careless or unartful Manner, it takes quite a contrary Effect, and the Wool falls to Pieces.

When the Wool, on trying it, draws well and holds together, the Quantity of the Oil is right. The Eye and the Hand will judge of this, when People are very much used to it, but there is no Way so sure as this of Trial. In general Wool requires somewhat less than a third Part of its own Weight of Oil for this Operation. Therefore that those who are not used to the Manufacture may proceed upon some Certainty, let them first weigh the Wool, and to every three Pounds of it allow a Pint of Rape Oil, bare Measure; or to every ten Pounds of Wool three Pints of Oil: let about two Thirds of this be used at first, and then the Wool tried on the Wheel, for sometimes this will do; and if not, let some more of the Quantity be used, but carefully and with great Discretion.

Oil is the common Thing used for this Purpose, but any greasy or fatty Substance will do: and indeed any Kind of Oil. Where Rape Oil was not to be had I have seen other common coarse Oil used; and many a good Housewife has made Hogs Lard answer the same Purpose; but the Oil mixes more easily, and more thoroughly with every Part of the Wool. When Hogs Lard, or any other solid fatty Substance, is employed instead of Oil it must be melted, and very carefully sprinkled on while it is fluid, and mix'd well in by turning and softly working with the Hands.

CHAP. XLII.

Of tumming and spinning of Wool.

THE Wool may, for some Purposes, be spun as it comes from the Hand of the Housewife in the greasing; but the better Way is to use this only as a Preparation for the tumming. This tumming is another carding, and it brings it to a great Degree of Fineness and Suppleness; and makes it fit for all the Housewife's Purposes. The Method of tumming it properly and effectually is this.

When it is thoroughly oil'd or greas'd, and will hang in a Thread from the Wheel, let it be very well worked in the Hands, and then spread out as at first. Let a Pair of long-tooth'd Cards be made ready; and let it be very well carded and combed again, drawing it perfectly fine; and separating every thing that is knotty, tangled, or uneven. These Pieces, thus separated, are called Tummings, from the Name of the Operation; and they are to be reserved by themselves for other Purposes. They are not to be mixed with the first foul Parcel, because having gone through so much more of the Operation, they will be great deal finer than they.

The tumm'd Wool is now perfectly ready for spinning. The Wheels must be large, and a steady and careful Hand must be employed in the spinning it.

There is so much Difference between the Wool of one shearing and another, that all will not spin to the same Fineness. No Force is to be used in this, for it will not succeed. If any one should attempt to force a coarse Wool to run into a fine Thread, it would never answer in the other Parts of the Manufacture. Things must be taken as they are: and when the Wool is suffered to run from the Wheel well, as it naturally offers, it will be sure to hold good in every succeeding Process.

A judicious Person will see, from the Nature of the Wool, what Service it will answer from the Beginning, but this is not essential; for whether it be formed for a larger or a finer Thread, the same Care is to be taken of it in every Article we have already named. The Difference arises partly from the Breeds of Sheep, and partly from the Care taken of them in their Management; both these Articles we have treated of already, and therefore need not repeat what we have delivered on those Heads.

When the Wool is of a coarser Staple it should not be wrought into a fine Thread, for if this be done it will want Substance when it comes to the Mill; it will beat to Pieces, or never bed well, and consequently the Cloth will have little Strength, and do little Service.

In the same Manner if any one should force a Wool of a finer Kind to spin out into a thick Thread, being against its Nature, it would be greatly to its Disadvantage. In this Case a great Part of the over Thickness of the Thread must be taken away afterwards to waste, or the Cloth will wear coarse.

This is all the Caution required in the common Way of spinning, and the doing it properly and well depends, as we see, principally upon the keeping a regular Hand, and letting the Wool work according to its Nature; but a great deal more may be done by those who are expert. There may be two Kinds of Thread spun; and indeed it always should be so. Two Manners of spinning should make these two Kinds of Thread, which are called the Warp and the Woofe.

The Difference is this. The Warp is to be spun close, round, and hard twisted, and it should be strong and very well smoothed: the Woofe may be spun more loose, open, and but half twisted. The Reason of this will appear very plainly, when the Farmer considers their Use and Condition. The Thread of the Warp is to run through the whole, and to endure the fretting and beating of the Beam: the Woofe, on the contrary, requires no great Strength or Smoothness, because it only crosses the Warp without any Violence or Straining.

It is not only that the Woofe does not require the Firmness and Hardness of the warp Thread; but its being looser and softer makes it answer the Purpose better: it beds the closer and evener in the working, and the Warp has all the necessary Strength for keeping the whole together.

The Intent of the Woofe is to cover in and unite all together, and this is to be perfected by beating in the Mill. This is an Operation altogether needful to the Cloth, yet the less of it can be made to answer the Purpose the better. Now the proper spinning of the Woofe Thread is an im-

important Article in this Reſpect. Many a good Houſewife thinks ſhe never does well unleſs ſhe make one Thread as hard as the other, and therefore ſhe orders all the Parcel to be ſpun alike, thinking the leaving the Woofe thus open to be only a Piece of Idleneſs. But the looſer this Woofe Thread is the eaſier it is to make it cover, and the leſs beating it takes; the harder the more. This is an important Article, and has been much diſputed, but the Practice in the Cloth Countries, which is founded on long Experience, ought to determine it. 'Tis a common Opinion that the making both Threads hard, though it requires a great deal of beating to bring the Cloth to Form, yet gives it Strength: but this is proved an Error.

The Warp is the Thread on which the Strength of the Fabrick is to depend, and as to the other, its being hard is found to be of no Service. It makes the Cloth fret and wear, whereas the leaving an open looſe Thread for the Woofe, gives it a pliable Softneſs that prevents all fretting and cracking.

We hear every body of late ſpeak of the FRENCH Cloths; they praiſe them for their Pliantneſs and eaſy Wear; and though they are in reality greatly inferior to the ENGLISH in Subſtance, and many other Particulars, yet People prefer them for this Reaſon. A Deſire of being ſerviceable to my Country in this great Article, has led me to make Enquiries among thoſe who underſtand the FRENCH Clothiery, and I find it is altogether owing to their ſpinning two Threads out of every Parcel of Wool, and keeping one for the Warp and the other for the Woofe, the latter of which they make ſo looſe that 'tis hard to work it. The Conſequence is, that a very little beating brings the Cloth into a Body, and when finiſhed it is ſoft, pliant, and very fit for wear. One would think theſe FRENCH Cloths, by their Look, and by feeling of them, could do little Service, but the contrary is found upon Trial. They never crack, and the Looſeneſs of the Wooſe Thread riſing from time to time, keeps them from wearing thread bare. Our hard Cloths are very liable to grow bare at the Seams; theſe never do; becauſe they are leſs harſh. They are fitter for Gentlemen's Service than for labouring People; but it would be eaſy to follow their Practice more moderately, which is what we recommend to the Huſbandman, in preparing Cloth for his own Family, and then there would be more Service and more Credit every Way in theſe Cloths, than in thoſe which are made every Way with a harſh and hard Thread.

CHAP. XLIII.

Of the winding the Thread, and finiſhing the Work.

WHEN the Wool, after the dreſſing, oiling, and tumming, is ſpun into Thread, or Yarn, it is for Convenience to be wound. Thoſe who continue the old Houſewife's Practice of ſpinning it all alike, have nothing to do but to wind it off as it is finiſhed from the Broch, into a Clew or round Bundle. But the better Way is, as we have ſaid, to ſpin it in two Kinds, and wind each off in its ſeparate Clew, the warp Thread and the woofe Thread. In this Condition it is ready to be made into Cloth. The making it up is the Buſineſs of the Weaver, a Trade to be learned by an Apprenticeſhip, not by any Deſcription that can be given in Writing; nor is it our Purpoſe here, for we limit ourſelves to the Buſineſs of the Huſbandman alone, for whoſe honeſt Service this Work is written. However, though we are not to inſtruct the Weaver in his Profeſſion, yet it will be proper to inform the Farmer ſo far in the Nature of it as concerns himſelf; that is, to give him juſt ſo much Inſight into the Work, that he may know whether he has Juſtice done him or not.

In the firſt Place, before the Yarn is delivered to the Weaver, it is fit the Owner ſhould know how much Cloth it may make; I have known an ignorant Perſon cheated, in this Reſpect, of half, nay two Thirds, by the Villainy of the Weaver.

The Quantity of Cloth will be very tolerably determined by the Weight of the Yarn. We have adviſed the weighing of the Wool before, but it will be proper finally to weigh it again, when it is in the Clews: this is very eaſy, and as there may have been ſome Waſte in the former working, it is the beſt Method.

The general Computation, in the Language of the Workman, is, that it will run Yard and Pound; and this is in the common Run true, provided the Wool have been originally good, and the ſpinning carefully performed. If the Yarn be coarſe it will make leſs.

This being determined, the next Care is to obſerve how many Pounds of Yarn are laid in the Warp, and ſo many exactly muſt be reſerved for the Weft or Woofe. This is a Rule not univerſally practiſed, but there is none better. Even and even is the Practice of the beſt Workmen, when they have a Mind to make the beſt Cloth. There may be Differences, but they will be for the worſe, at leaſt they certainly will in the Cloths we are treating of, which are the common Kind for the Service of the Family.

If the Owner will carry his Obſervations farther, it will be ſo much more to his Advantage: though he cannot do the Weaver's Buſineſs, he can know when it is well done; and he ſhould over-look it often, to ſee that it be ſo. He is to obſerve that the whole be woven cloſe and true; and in every Part alike.

From the Weaver the Cloth is to be carried to the Fulling Mill, and there he may ſee alſo that the Buſineſs be done well and carefully. We have ſhewn him that ſome Yarn will make the Cloth require more milling than other: but if this have been ſpun well in the two Kinds, let him ſee that it have not more than it requires.

The ſcouring Earth is the next Article to be conſidered, and none is of more Importance. It is a moſt neceſſary Ingredient, but it may be a very hurtful one. Its Uſe is to clean, but it may tear the Cloth: its Fineneſs is all in all on this Head, for if it be coarſe, and the Work ill managed,

naged, it may very naturally and eaſily beat Holes in the Cloth.

From the Fuller the Cloth is to be carried to the Sheerman, and there, if the Eye of the Owner follow it, he will be ſure to have it the better done; he is to ſee that this Workman hurle it, and dreſs it ſufficiently; and ſheer it according to his Purpoſe: Moderation is the beſt Rule. If it be left too rough it will not wear clean, and if too cloſe it will be ſoon thread-bare.

CHAP. XLIV.

Of the dying of Wool.

THE Huſbandman will conſider in this Place, as in the preceding Chapter, that we are writing ſolely for his Service, and the Reader who has Candour will not purſue the Subject farther in this Place; nor cenſure us for having conſidered it thus far. We do not intend to teach the Art of Dying, any more than we attempted before to inſtruct our Huſbandman in the Trade of Weaving. We only aim to give him all the Information that may be needful; and to lead his Curioſity no farther. We have, in the laſt Chapter, told him how he is to judge of the making up of his Cloth; but in this we ſhall proceed a little farther. We ſhall not enter into the Buſineſs of the Dyer at large, but ſhall ſhew the Countryman how he may, in thoſe Inſtances that ſerve his common Purpoſe, tinge his Wool at a ſmall Expence, and do in a Manner all within himſelf.

The Colours the Countryman will deſire to give his Wool, may be reduced to a ſmall Number. Black, red, blue, green, and yellow, may be named as the five Principal, and if we add to theſe a pale Purpliſh, an aſh Colour, and Hair Colour, from one or other of theſe, and the Mixtures compoſed, as we ſhall ſhew from theſe variouſly combined, he will draw all the Variety that he deſires.

For blue, grind in a Mortar a Pound of Indigo-blue, and mix it with two Gallons of ſtale Urine, ſet it on the Fire, ſtir it well together, and put in the Wool when it is made moderately hot. Let it continue ſome time, and it will have a good ſtrong blue Colour.

The Quantity of the Ingredients muſt be proportioned to that of the Wool; and the beſt Time for dying it is before the oiling.

To die black beat to a groſs Powder two Pounds of Galls, put them into a Pot with two Gallons of River Water, put to them one Pound of common green Copperas, boil them up well together, and the Liquor will be like Ink. Put the Wool into this and boil it. Then let it cool, take it out, and hang it to dry.

To dye red ſet on a Quantity of River Water, in a large Earthen Veſſel. When the Water is ſcalding hot put in a Peck of Wheat Bran: let this boil a few Minutes, then pour it into a Tub, and put to it twice the Quantity of cold Water. Set this by for a Week. Then weigh the Wool you intend to dye red, put it into the Water and Bran; and with it, to every ten Pound of the Wool, one Pound of Allum. Let theſe boil together an Hour: then take out the Wool. Beat to Powder a Pound of Madder Root, put it into Bran and Water, and when it is hot, and the Madder is well mixed with it, put in the Wool, break and divide it well with the Hands; and when the Liquor is ſo hot the Hands cannot bear it, ſtir it about with a Stick; when it is well coloured take it out; and hang it up to dry.

To die yellow boil the Wool in Allum Water, made as ſtrong as before directed; then take it out, and hang it to dry. Set on a large Pot with River Water, and a good Quantity of Dyer's Weed, of which, as alſo of Madder, we have ſpoken in their Place. Put the Wool into this, divide and break it well, that it may receive the Colour throughout, and it will thus become of a very good ſtrong yellow.

To die green, the Huſbandman's beſt Method is firſt to die his Wool blue, as we have directed already: when it is dry in this Colour let him ſet on a Pot of Water with Dyer's Weed, and put in his blue Wool. It will receive the Die in the ſame Manner as the other, and by a natural Conſequence the Wool become green; becauſe a Mixture of blue and yellow is always green.

To die a pale Purple the ſame Ingredients are to be uſed as for dying black, only in leſs Quantity, and in a different Management. The black is only a purple carried to that Extremity. This is plain from Experiments eaſily tried. The ſame Ingredients that make this black Die make Ink, and they will always make purple inſtead of black in a ſmaller Quantity. If Copperas be diſſolved in Water, the Liquor will be clear. Then let Galls be boiled in Water, and ſome of that being dropped into the other it will raiſe a purple Cloud, and when more is added it will be darker, till it become quite black. In the ſame Manner this Die, which is for black in the common Way, may be made to anſwer for a pale Purple. It is to be done thus.

Bruiſe ſome Galls to a coarſe Powder, ſet them over the Fire in a Veſſel of River Water, and when the whole is hot put in the Wool. Let it boil half an Hour, then take it out and hang it to dry. The Colour of the Wool will be ſcarce at all altered by this. Let the Liquor be poured off clean from the Galls, and put to it a ſmaller Quantity of Copperas than is ordered for black dying. The Liquor will inſtantly become black. Draw the Wool lightly through it; and it will get a pale purple Tinge. If it be not deep enough put it in again. The Care muſt be not to make it too deep.

To die Hair Colour ſet on a Pot with ſtrong Allum Water: boil the Wool in this, and then take it out.

Then mix together a good Quantity of Soot and Urine, and when they are hot put in the Wool. Let it remain a moderate Time, then take it out and hang it up to dry. This makes a very good, ſerviceable, and laſting Colour.

To die Aſh Colour make a Liquor in the ſame Manner as for the pale Purple, but inſtead of putting in the Wool boiled only in Galls, uſe Wood died red, as before directed, with

with Madder. This will make a very pleaſing Aſh Colour, with a light Glow of the red, which will be very agreeable.

We have thus laid before our Huſbandman the Method of dying all the uſeful plain Colours, in an eaſy and cheap Manner; and ſhall, in the ſame Way, ſhew him how to make a Variety of Mixtures in his Cloth from theſe ſimple Dyes in the Wool. The Dyers uſe more laborious Methods, and more expenſive Ingredients; but this is ſufficient for all the Purpoſes of the Country Farmer.

We have directed the Wool to be dyed before the ſpinning, which is by much the beſt Way; and in treating of the mixed Colours for Cloths, in the next Chapter, we ſhall purſue the ſame Method, ordering them to be made from the looſe Wool thus dyed; nevertheleſs, if any chuſe it, they may in the ſame Manner, and with the ſame Liquors, dye the Yarn or Thread after it is ſpun, or even the Cloth after it is wove. Circumſtances may ſometimes render this Management neceſſary, though the other is preferable.

CHAP. XLV.

Of mixing the coloured Wools for weaving.

OUT of the plain Colours we have directed the Farmer to die, it will be in his Power to make ſeveral Mixtures, and thoſe for Service are frequently better than the ſimple Colours themſelves. The Time for doing this is when the Wools are dry, and before they go through any other Operation. Indeed nothing prepares them ſo well for ſpinning; for nothing renders them finer than the neceſſary Diviſion of them in the mingling of their Colours.

If the dy'd Wool be intended to be wrought up in its plain Colour, it is to be treated exactly as the white in all Reſpects, oiling, tumming, and the like; therefore nothing on that Head need be ſaid farther: but if it be intended for Mixture, that is to be made before any thing elſe is done to it.

Mix'd Colours may be compriſed under two Heads, thoſe which are compoſed only of two, and thoſe compoſed of ſeveral.

Of the firſt Kind the beſt are thoſe made up of the darkeſt and the lighteſt or brighteſt Colours, for theſe give a Spirit: whereas two light, or two dark Colours together, make no conſiderable Variations.

The Proportions of the ſeveral Colours in theſe Mixtures, may be varied in a Manner without End; but there is one Proportion which is in general better than any other, and is therefore worthy to be advanced into a Kind of fixed Rule. This is when a proper light and a proper dark Colour are choſen, to weigh two Pounds of the dark, and one of the light, for the Mixture, and in the ſame Manner for any larger Quantity, the bright Colour being only one third Part of the whole. Thus if we ſuppoſe blue and red to be the two plain Colours, of which a Mixture is to be made, and the whole Quantity intended to be uſed to be fifteen Pounds; in this Caſe there ſhould be ten of the blue and five of the red; and ſo in all other Caſes.

The Colours thus produced are what are called mixed Colours in a diſtinct Manner, for when more are uſed they are called Medleys; and the Way is this. Suppoſe three Colours for Inſtance are to be mixed, if two be dark and one light, the Method is to take an equal Quantity of each of the light Colours, and twice the Weight of both the others, of the dark one; on the other Hand, if it be a Medley of two dark Colours and one light, then an equal Quantity of each is to be taken, and they are to be perfectly well mixed together.

When the Wools of theſe ſeveral Colours are weighed out, a large Sheet is to be ſpread upon the Ground, and upon this is to be ſpread an even and thin Layer of the darkeſt Colour, or of one of the dark Colours, when two are equally dark: upon this is to be ſpread another Layer of the lighteſt Colour, and ſo on interchangeably Layer over Layer, till the whole Quantity of Wool that was weighed is ſpread on the Sheet.

Then this Wool is all to be rolled up into one thick, hard, and ſtiff Roll. The Way is to begin at one End, and carefully turn up the Edge round itſelf. This makes a Beginning, and the reſt all rolls upon it very eaſily; a ſteady Hand is to be uſed, and the whole will be thus brought into one long thick Maſs.

One End of this Roll is then to be made faſt in a Frame, or a Perſon is to kneel upon it, to keep it from moving or untwiſting, and beginning at the other the whole is to be pulled out into ſmall Pieces. The ſpreading and rolling of the Wool had before very tolerably mixed the ſeveral Colours, but this does it entirely; the whole will now be an uniform Maſs of a medley Hue, as if dyed of three or more Colours together.

When this is done the Wool is all to be carded and combed together, by a Pair of Stock Cards well fixed to a Form.

This compleats the Mixture, it grows into an even and perfectly uniform Maſs; and if there be any Knots or Lumps in it they are to be carefully ſeparated.

This combing is to be done exactly in the ſame Manner as in the Management of white Wool, before deſcribed; and after this the oiling, tumming, ſpinning, winding, and warping, are to be performed in the ſame Manner. The Cloth thus made has a very good Look, and wears clean: none is fitter for the Service of the Family.

The Farmer or his Wife may thus, without farther Information, perfectly well go through ſo much of the Wool-Dreſſers and Dyers Buſineſs as is neceſſary for their own Concerns, and in Places where thoſe Trades are not at Hand it is a very great Convenience to be able to ſupply their Places at Home.

CHAP. XLVI.

Of Hides and Leather.

THE Wool being diſpoſed of either at the Market alone, or partly at Market, and partly wrought up for the Service of the Family, the

the Care of the Hides of Sheep, Oxen, and other Beasts remains, and is the Farmer's next natural Consideration.

Hides are of various Kinds, according to the Creatures from which they are obtained; and they are accordingly put to various Uses: and they may, like all the Farmer's other Products, be sold by him either rough, or with some Degree of Preparation. The entire Dressing of them is the Business of a distinct Trade, or indeed, taking in the whole Course of the Subject, of several Trades; however, it is proper he should know so much of the intended Operations, as to be able to suit his Hides, as far as lies in his Way to them.

The Skin of the Cow and Ox Kind is so much above the others in Use, that it has, in a Manner, appropriated the Word Hide to itself; those of these Creatures being called, in the common Way of speaking, Hides, and those of other Animals Skins.

The Farmer usually sells his Oxen or Cows alive at Market, or to the Butcher, and has no farther Care about them; but it may happen that he have Occasion to kill them sometimes himself. The Hide then is sold separate. If he dispose of it just as taken off from the Carcase, it is called a green Hide or a raw Hide: but this is generally the least advantageous Method of disposing of it, because the Purchaser knows it will spoil upon the Farmer's Hands, if he does not know what to do with it farther, and therefore that he will take what is offered for it.

We shall prevent this Imposition upon our Husbandman, by acquainting him what may be done to preserve it.

In the natural Course of Things a Hide will keep a great deal longer in Winter than in Summer. Those who deal in them largely are forced often to keep them some Time; or to send them to a considerable Distance before they are wrought. And in this Case they have a Way of preserving them with Salt: this is in the Farmer's Power, as well as theirs: the Hide will not be at all damaged by it, and he may preserve it thus to a better Market.

A good Quantity of common Salt is to be mixed with a tenth Part of its Weight of Allum beat to Powder. The Hide is to be spread upon a Floor, and a stout Fellow is to rub and work this in well with his Hands all over it, and particularly where there are any Crevices, or thicker Places than the rest: when it is thus well salted it may be kept some Time. The best Method is to double it up, and lay it on a Shelf in a Cellar.

This will answer the Purpose of keeping it some Days; but if a longer Preservation be required, for the getting a Number together, then two Days after this first salting let it be spread out again and rubbed well with Salt and a little Salt Petre. A Hide will thus be preserved any reasonable Time.

Hides may be preserved dry in the Hair, by carefully hanging them up single in an airy Place, wiping them frequently and turning them till they harden: and in this Way they will be in the same Manner capable of being put to use; but it is not nearly so well as the other.

The Buffaloe Hides from some Parts of AMERICA, are sent over in this Manner, and are dressed afterwards.

The Hides of the Cow and Ox Kind fall into the Hands of the Tanner afterwards, for tanning into Leather; but those of other Creatures, both here and in other Parts of the World are dressed by other Trades, for different Purposes. Shagreen is a Skin prepared in a particular Manner; and Parchment and Vellum are also Manufactures of Skins.

The Skin of the Sheep is the proper Material for making into Parchment, though in some Places Goats Skins are used for the same Purpose.

Vellum is made of the Skins of sucking Calves: and Shagreen of the Skin of the Buttocks of an Ass. This last is a Manufacture of the East.

Chamois, or as it is commonly called, Shammy Leather, is made of the Skin of a particular Kind of Goat; but it is commonly in ENGLAND no other than Sheep Skin dress'd in a particular Manner.

The Skins of Sheep and Calves dressed in other Ways, make also Leather of various Degrees of Value for the covering of Books, and other such Purposes: the Calf Skin being always much more valuable than the Sheeps.

The Farmer sees here what are the Uses of his various Hides, and will know by this general Account, that he need not want Purchasers for all Kinds. The Principal, which are the Hides of the Ox Kind, go to the Tanners for making into Leather; and he is ready to receive them in either of the three Conditions we have named, that is, green, salted, or dried. He throws them into Pits with Lime, and Oak Bark, and by that Means takes off the Hair, and hardens the Skin for the various Purposes. The Tanner, when he has gone through his Business, delivers the Hide to the Currier, who finishes the Preparation and delivers it for Use.

We shall not attempt to inform our Husbandman in these Particulars; they are separate Trades, and never can fall within the Compass of his Practice. All that he can be required to know is how, to whom, and in what Manner to dispose of the Skins and Hides, which we have shewn him, with their general Uses.

End of the TENTH BOOK

A COMPLEAT BODY OF HUSBANDRY.

BOOK XI.

Of making Beer and Cyder. In TWO PARTS.

PART I. *Of* MALT LIQUOR.

CHAP.

1. *Of making Malt.*
2. *Of the drying of Malt.*
3. *Of the ſeveral Kinds of Fuel uſed in drying of Malt.*
4. *Of the right Management of Malt, and of Additions to it.*
5. *Of the ſeveral Kinds of Malts and Waters.*
6. *Of Brewing in general.*
7. *Of Brewing in private Families.*
8. *The Advantages of Brewing at Home.*

PART II. *Of* CYDER.

9. *Of chuſing a Spot for an Orchard.*
10. *Of diſpoſing the Orchard.*
11. *Of making the Plantation.*
12. *Of the common Management in the making of Cyder.*
13. *The Reverend Mr.* GEORGE TURNER'S *Method of making Cyder.*

The INTRODUCTION.

IN this, as in the preceding Parts of this Work, we ſhall lead the Huſbandman in the Road of Reaſon and Experience; conſidering what has been written as it deſerves; and much more what has been practiſed as it has come to our Knowledge: we ſhall begin from the Foundation, that he may be acquainted with every Part, and underſtand every thing that is directed to be done from the making of the Malt to the brewing and fining down of the Beer in its different Kinds, and for its ſeveral Purpoſes.

BOOK XI. PART I.

Of MALT LIQUOR.

CHAP. I.

Of making Malt.

MALT is a Preparation of Barley, fitting it for impregnating Water with its Taſte and Qualities, in the moſt pleaſant, wholeſome, and advantageous Manner.

We ſhall not trace the Subject farther back than to the thraſhed and cleaned Barley, in this Place; becauſe we have brought that Grain from the Seed to the perfect Corn, in a due Courſe of Huſbandry in a preceding Part. Only we ſhall add, that as the beſt Barley will always make the beſt Malt, ſo there is an Advantage alſo in its having grown on a proper Soil, and in its having been dried by a right Management. On theſe two Articles depend the Quality of the Malt. In general that Barley which is tendereſt and moſt mellow, is beſt for the Purpoſe; that which is hardeſt is worſt.

The Manufacturers call this laſt ſteely Barley, and they always avoid it as much as they can, knowing it will give them moſt Trouble, and ſucceed the leaſt in the Brewing.

It would not be of much Conſequence to the Generality of thoſe who brew, to acquaint them with the Advantages of taking the Grain from a proper Ground, and drying it in a proper Manner, for the mellowing of its Subſtance; becauſe they cannot know thoſe Things, but muſt receive it as it comes: but we are here writing to the Farmer, who is to make his Malt from Barley of his own growing and drying: he therefore may chuſe ſuch of his Grain in this Kind as will be ſure to anſwer beſt for this Purpoſe.

The beſt Barley for making into Malt is that which has been raiſed on a chalky Soil, and the worſt of all is that which has grown on Clay. The Difference, in this Reſpect, is greater than any would conceive that have not tried it, the Barley that has grown on Clay being naturally hard, and the other naturally tender.

As every Farmer will not have chalkey Soils among his Grounds, we are to tell him in general, that the tougheſt and ſtiffeſt Lands yield the worſt Barley for Malt; and the lighteſt and melloweſt the beſt. Therefore let him remark ſuch as grows on the lighteſt Soil he has, as fitteſt for this Uſe.

When he has fixed upon the proper Field of Barley for this Purpoſe, let him ſee it be managed according to the Deſign. Good Malt requires that the Grain be full ripe, and perfect in the Ear. It is a common Piece of Neglect to mow Barley at random, often before it is ripe: in this Caſe the Corn is lean, and will never yield a rich Malt.

When it has ſtood to a proper Degree of Ripeneſs for mowing; it muſt be carefully dried after cutting: for if it be houſed before it is properly ſeaſoned, it will contract an ill Taſte, and will make poor Malt, beſide that it will give a great deal of Trouble in the making; not coming, as they expreſs it, ſo regularly as other better Grain. The Barley being thus far properly managed, is to be thraſhed and carefully cleaned, and then it is ready for malting.

Making of Malt is no more than ſoftening and mellowing the Flour of the Barley, and then properly drying it. It is mellowed by Means of Water, and it requires a different Time of ſteeping for this Purpoſe, according to the Nature of the Grain.

Such a Quantity as the Farmer intends to uſe for this Purpoſe, is to be put into a Leaden Ciſtern, or other Veſſel, and Water is to be poured in till it be ſix Inches deep above the Grain. This will allow for the ſwelling, and this will do the Buſineſs in two or three Days, according to the Nature of the Grain; the fineſt Barley always taking the Water the moſt kindly. In order to know when it is ſteeped enough, a Grain is to be taken out, and held end-wiſe between the Thumb and fore Finger, preſſing it gently. If it be hard and ſtubborn it is not ſteeped enough. When it is in right Order it will yield and give Way a little; there will be a Softneſs perceived in the floury Part or Body of the Grain; and the Huſk will ſtart or part a little from it: this ſhews it is juſt in right Order.

The hitting this Time exactly is the niceſt Part of the Art of Malt making: for if it be not ſteeped enough it will not anſwer well in the reſt of the Proceſs; but will give great Trouble, and make imperfectly; and on the other Hand, if it be ſteeped too long it will loſe its Flavour and its Strength: the Beer that is made from it will have a Deadneſs from the firſt, and no Quantity of the Hops will make it keep well.

When the Barley is in this right Condition, the Water is to be drained from it, and it is to lie to come on the Floor: this it will do in a little more than twelve Hours, in favourable Weather, but ſometimes it will be twice or three Times as long.

From the Ciſtern it is to be put into a ſquare Hutch, and there it is to lie quiet about thirty Hours. Then it is to be worked Night and Day, in one or two Heaps, as the Weather is hot or cold, and turned about once in ſix Hours, the outer Part inwards, and the Bottom upwards; always keeping a clear Floor, that the Corn lying next it may not be chilled.

This Care is to be continued till the Malt begins to ſpire, or, as the common Expreſſion is, to come: after this it is to be turned once in three or four Hours; and as it comes more the Heap muſt be ſpread wider and thinner, to cool it. The beſt Method is to lay it out in general in Parcels two Foot and a half thick, and about ten Foot broad, to come and chip gradually, for it ſhould neither ſpire too much nor too quick.

When it is come enough it is to be turned once in two Hours or leſs, for four and twenty Hours together; and when it is fixed, and the Root begins to be dead, it muſt be thickened again, and often turned and worked about, that the growing of the Root may not revive.

A diligent and induſtrious Man is to be employed for this Purpoſe, and he ſhould be without Shoes for fear of damaging a great deal of the Malt. He muſt be careful to turn it frequently and thoroughly, and keep a clean Floor: for if he be remiſs in the Management at this Time, the Malt will either mould or ſhoot out in Leaf. This laſt is the moſt common Accident attending ill Management at that Time of the working; and it is what the Malſters call acro-ſpiring. In this Caſe the fine Flour of the Malt is exhauſted in this uſeleſs Shoot, and the reſt is a Kind of Chaff.

When the Malt is ſo turned as that the Danger of both theſe Accidents is over, it may be put into the Kiln; but a better Way is to throw it up into a large Heap firſt; in which, being in no Danger of ſhooting, it may lie twelve Hours, which will mellow it in a ſurpriſing Manner. After this it ſhould be ſpread and turned once in ſix Hours, and this repeated four Times.

The Weather is a great Article to be conſulted in Malt making, and its Changes make ſo great a Variation in the Proceſs, that no fixed Rule can be eſtabliſhed. Twelve Hours is about the Time it uſually requires to mellow in this Heap, but ſometimes an Hour or two leſs, and

ſometimes an Hour or two more will be better; the Intent is, that it ſhould mellow kindly without heating too much, and this muſt be tried by examining it; for if it heat too faſt it will be greaſy and of little Value. In the ſame Manner all the other Times of turning muſt be varied according to the Temperature of the Air. The Farmer ſees what is the Intent and Deſign of the Work, and he is to turn it an Hour ſooner, or an Hour later on any of the Occaſions we have named, according to the Nature of the Opportunity. If he make his Malt himſelf this is a very material Part of Knowledge, and, as in other Occaſions, if he do not, it is fit he ſhould underſtand every Part of the Proceſs, that he may know whether thoſe to whom he puts it to be made do him Juſtice.

When the Malt is in the Condition we have named, it is to be brought to the Kiln, there to be dried according to its Nature.

CHAP. II.

Of the drying of Malt.

THERE are various Degrees of drying Malt, according to its intended Uſe; and different Contrivances for the doing of it.

In general the paler the Malt is to be, the more gradual and gentle muſt be the drying: this is the general Rule, and in this there is to be a great deal of Variation. The paleſt Malt will require ten Hours or twelve in drying, whereas the browneſt will be very well dried in four, and a middling Kind in ſix or ſeven Hours.

There is a great deal of Variation in the Opinion of Malſters, about the Thickneſs the Malt ſhould lie upon the Hair Cloth for drying. Our Anceſtors were ſo careful they ſpread it very thin, they rarely let it lie at more than three Inches deep: our late Improvers, as they call themſelves, lay it ſix Inches or more; but this is a very great Error.

By all that I can ſee from repeated Trials, about four Inches is a proper Thickneſs: and in this Manner about a Space of fifteen Foot ſquare will dry two Quarters of Malt.

It is not to lie here all the Time quiet. It muſt be turned upon the Hair Cloth as upon the Floor, and this more or leſs frequently, according to the Nature of the Fire, and the Time intended to be allowed for the drying. If the Fire be gentle, and 'tis a pale Malt, that is to have ten or twelve Hours on the Hair Cloth, then once in four Hours is very well for the drying: if it be a Kind that muſt dry quicker, once in two Hours will be a proper Method: obſerving in this Caſe, as on the Floor, to keep a clean Bottom.

When the Malt is ſufficiently dried, whether by a quicker or a ſlower Fire, it muſt be thrown off from the Kiln to the Floor, and ſpread thin and wide in an airy Place, that it may perfectly cool. Then it is finiſhed and fit for Uſe.

There is not, in all the common Arts of Life, any that requires ſo nice a Caution as the making of Malt. The Time muſt be conſidered: three Weeks is a moderate Allowance, often it will take much longer.

As different Lengths of Time are required for the drying the different Kinds of Malt, there have been alſo invented various Ways of doing it. The Iron-plate Frame, and the Tile Frame, both full of ſmall Holes, are much eſteemed by many; others prefer the Braſs-wire and others the Iron-wire Frame; and others the Hair Cloth: the Huſbandman is not to give his Voice in Favour of any one of theſe in general Terms; but to conſider the Uſe it is intended to anſwer: the Nature of the Malt to be dried is a material Conſideration, for that Kind will do for one that will not for another; and when the moſt expeditious can be uſed, without Hurt to the Malt, there is ſomething worthy Conſideration in the ſaving of Fewel.

Thoſe which do with the leaſt Fewel are the Iron-plate Frame and the Tile Frame: they were invented for this Purpoſe, and are a ready and cheap Method. They dry the brown Malts very well, but they will by no Means anſwer for the pale Kinds.

None of the Methods heat the Malt ſo violently as theſe, the Corns often jump like parched Peaſe, and crack: but they get a fine brown. It is a cheap Way of drying; but let the Farmer ſee he is not deceived in it, eſpecially if he be to buy Malt of this brown Sort. The Nature of it is to look dry, and it is not the worſe for that; but thoſe who ſell it, frequently ſprinkle Water over it, which it receives freely, and this makes it ſwell up vaſtly. 'Tis fairer to the Eye, but this is a Trick that takes away a great deal of its Sweetneſs.

People find the brown Malt dried this Way apt to ſpoil in keeping: but they accuſe the Machine when the Malſters are in Fault: all the Damage they find in the Malt is owing to the ſprinkling Water over it; which they are apt to do on all Occaſions, to make their Work appear well; and this ſubjects it to decay in keeping. Brown Malt, dried on one of theſe Frames, will keep as well as any, if it be ſpread to cool as ſoon as made, and no Tricks be play'd with it.

All the real Damage it is ſubject to is, contracting ſomething of a Bitterneſs by burning; and this owing to the Careleſſneſs of the Maker, more than the Fault of the Frame.

This Careleſſneſs of ſome, and the Tricks of others, have brought theſe Methods of the Plate and Tile Frame out of Faſhion, but without any real Cauſe. They are fit only for brown Malts in their Nature, but in a fair and proper Management they dry theſe as well as any other of the Methods, and much cheaper.

The Wire Frame comes next in Degree after the Plate and Tile ones, and it is generally uſed in their Stead. This dries the Malt more gently and leiſurely; but there is ſome Difficulty in the turning it, and cleaning the Bottom.

Of all the Methods that have been invented, the plain and ſimple Hair Cloth is the beſt for nice Work, and the fineſt Malts. A ſlow Fire under this dries it very gradually and equally, it is eaſily turned as is required, and when it is done there is no Difficulty in getting

it

it out, for 'tis only turning it at once and all is clean and clear.

CHAP. III.

Of the Fuel to be used in drying Malt.

WE have shewn the Farmer by how many several Ways Malt may be dried in Respect of the Frame, and there is also a great Variety in the Article of Fewel, which he must consider in the same Manner: some Kinds being cheaper, some dearer; and some better, others worse. However this is not so absolute a Character, but that some of those which are bad for the drying certain Sorts, may be very proper for others.

The principal Kinds of Fewel, including the Practice of the several Parts of the Kingdom, are five: 1. Coak; 2. Welch Coal; 3. Straw; 4. Wood; and 5. Dry Fern or Brakes.

The Farmer will understand that what is to be done by this Fewel is to dry the Malt, and nothing more. No Flavour is required from it, and therefore the purer the Fire is, and the cleaner the Malt is dried by it the better.

All Smoak must be wrong upon that Consideration; and therefore all those Fewels that yield a great deal of Smoak, are to be rejected in the drying at least of the nice Malts.

Upon this Consideration the Farmer will perceive, that Fern must be a very bad Fewel for this Use: and at first Sight a Person might join Wood and Straw under the same Denomination, because of the Quantity of Smoak that rises from them in burning: but there is in this a Difference. All Smoak is an Enemy to Malt; but there are Varieties, and those very great ones, in the Taste and Flavour of the Smoak of different Materials. Thus the Smoak of Fern is not only vety plentiful, but of a very ill Hogoe, which it will communicate to the Malt. And on the other Hand, the Smoak of Straw, though almost as plentiful as that of Fern, is so sweet, that it scarce does the Malt any Damage. The Smoak of Wood is of a middle Nature between both, not so sweet as that of Straw, nor so rank as that of the Fern.

Thus dividing our Fewel into two general Kinds; the Coak and Welch Coal being the best, and the Straw, Wood, and Fern the inferior, we have here the Degree of Goodness of these latter three; the Straw is the best of them, the Wood the second, and the Fern the worst.

There never can be a Necessity of using Fern on this Occasion, therefore it ought wholly to be excluded from the Malt-house. As to Wood it may always be had, and must be better than Fern; and for some of the ordinary Malts it is a cheap Fewel, and answers very well. Straw, with good Management, may be made to do for any but the very best and nicest Kinds.

With Respect to the other two Coak is the best; but the other is very good.

We advise the Husbandman to use Coak, if it is to be had; but let him see that it be good and well made: for otherwise the inferior Fewels may do better. Fine Coak is made of large Pit Coal charr'd, or burnt to a Cinder. It is to be burnt till all the ill Smell is consumed, and no Smoak rises from it; and in this Condition it makes the steadiest and the sweetest Fire of any Fewel whatever. It is a common Negligence to char this Coal imperfectly, but the Husbandman who dries his own Malt should examine strictly into it; for one smoaky Piece will do vast Damage. He may see this by the Eye, for there is a particular dry Aspect which Coak has when perfectly burnt, that is wanting in such as has any of its gross Parts remaining.

The next to pure Coak is Welch Coal: this is called by many Culm. It is a fine sweet Coal dug naturally out of the Ground. It comes in thin fleaky Pieces, and burns to white Ashes with a little Flame, and no Smoak, or very little. This brings it nearer to the Nature of Coak, but it is not altogether so pure: however, it is cheaper in many Places, and for all but the fine Malts will very well answer the Purpose.

Therefore let the Farmer, if he have Convenience, dry his own Malt, for out of this Variety of Materials it is possible the Malster to whom he puts it may chuse the worst: in some Places it will not be worth while, because every thing must be built for it, and that the Farmer may not think this proper, when he has a small Family: but in other Places most of the Conveniences will be ready.

In the Hop Countries the same Kiln that dries Hops will dry Malt; and so on many other Occasions: and wherever it can be done 'tis much best for him to do it at Home. As to a little Expence, let him consider 'tis a thing for which there is a constant Demand.

I shall offend the Malsters; but I must add, that if he knew their Practices as well as I do, he would see more Reasons than are here set down for doing his Business himself.

CHAP. IV.

Of the right Management of Malt, and Additions to it.

WE have observed, that to have perfect good Malt the Barley must be in perfect Order; and in this Respect the sweating in the Mow is a great Article. Nature intends some such Practice in the finishing of all vegetable Juices. We find that Apples carried from the Tree to the Press make a poor raw Cyder; and 'tis the same with the Barley: as the Apples must lie in a Heap, the Barley must be packed some Days in the Mow. I have known some Farmers, to save Trouble and Time, thrash their Barley from the Cart which they intended for Malt; and I have shewn them the Effects of their Error. The Malt has been poor, steely, and hard, in spite of all the Care in making; and no Art whatsoever could brew good Beer with it.

Pure Malt requires no Addition for the makeing of fine Beer, but Fancy or Curiosity have led People to make it various Ways, and some not amiss.

A small Quantity of Oats are added by some: but 'tis a Practice I cannot approve. The first

In-

Invention of this was owing to a Suſpicion of the Malſter. A Farmer who had been careful of his Malt Corn would put in the Oats, that it might not be changed: and as a very ſmall Quantity anſwered for that Purpoſe, there was not much Harm. But when thoſe who did not underſtand the Reaſon of it came to put in more by Way of an Improvement of the Drink, the Error was ſoon ſeen. As to this Practice all to be ſaid is, Oats hurt the Malt; ſo the leſs of them the better; but ſo much as will anſwer the Purpoſe of preſerving it to the Owner, may be done without any great Harm.

Others mix Beans or Peaſe with their Barley for malting. This ſeems a more unnatural Addition, but I have known it anſwer very well: ſuch a Kind of Malt, ſuppoſing it to be well made, and of a very good Barley, will make a mellower Drink than any other.

A very ſmall Quantity anſwers the Purpoſe of this Addition, a Peck and half of either is enough for five Quarters of Barley; and Peaſe anſwer the beſt. The Taſte and Qualities of both are much the ſame, but the Peaſe come better, and mix more conveniently with the general Quantity.

Though the Farmer may thus make ſome Additions to his Malt, he muſt be very careful that none are made by Accident for him. We have ſpoken at large of cleaning the Corn, in a preceding Part of this Work, and ſhall obſerve to the Huſbandman here, that there is no Occaſion which requires it to be ſo perfectly pure as this of malting.

The Seeds of many Weeds will get in among it, and ſome of theſe are very hurtful. 'Tis ſaid the Seeds of Cockle give the Beer an intoxicateing Quality, and in ſome Places Melilot is a common Weed in Corn Fields. This is a moſt miſchievous Addition to Malt Corn; for the Seed of Melilot is a very ill taſted, and a very ſtrong taſted one. It gives a diſagreeable Flavour to the Beer, and no Art can remove it.

Tho' Oats mixed with Barley hurt the common Kinds of Drink, yet they may be malted alone, and will make a very pleaſant Liquor; what is called Oat Ale, where genuine, is made of them, and it is then a ſoft and mellow Drink, not ſtrong, but very pleaſant.

Malt may alſo be made of Wheat, and a very ſtrong and very fine Kind of Drink is to be brewed from it: but this is a Concern the Farmer has no Buſineſs with.

Whichever Way Malt is made it anſwers the ſame Characters, if the Work have been well performed; and there are Methods of knowing by Trial, whether it be well made and in good Order or not. 'Tis fit our Farmer know them, that he may be able to try both his own Malt, and that he buys.

A fine Malt ſhould be full of Flour, mellow within, thin ſkin'd, and of a pleaſant Smell. The ſureſt Way of trying is by biting a Corn of it croſs-wiſe.

Another very good Method is to try it by Water. This Trial depends upon the following Principle. Barley, in its natural State, ſinks in Water; but malting, when it is well done, makes it ſo light that it ſwims. Therefore to try whether it be well made, let ſome fine whole Grains be picked out and put into a Glaſs of Water. If the Malt be mellow they will ſwim, if but imperfectly made they will ſink like raw Barley. The Corns muſt be perfect for this Trial, otherwiſe the Water will get into them, and they will then ſink, though ever ſo good.

The Lightneſs in the Hand is alſo a good general Way of trying: and alſo the drawing it carefully acroſs a Board; for good Malt will mark it white.

The Farmer will, by theſe Inſtructions, know how to make or buy good Malt, and we ſhall now tell him how to uſe it.

CHAP. V.

Of the Kinds of Malts and Waters.

TO lead the Huſbandman on to the practical Part of brewing, we ſhall firſt lay down a few Hints reſpecting the Nature of the Ingredients. Malts, ſuppoſing the Barley to have been equally good, may be divided into three general Kinds, from the Method of making: theſe are, the Pale, the Amber, and the Brown.

The Pale has a great deal of Time, and a very gentle Fire in drying; the Amber has a middle Degree of Fire, and a moderate Time; the Brown is the quickeſt dried of all.

The Pale is the richeſt, and it ſells for the beſt Price: it may be brewed with Well Water, but the others require ſuch as is ſofter.

The Amber is an excellent Kind of Malt, and the beſt Way of brewing it is with a Mixture of hard and ſoft Water.

The Brown is the higheſt dried, and requires River Water.

Theſe ſeveral Kinds of Malt may be dried with any Kind of Fewel, becauſe it is only moderateing the Degree of the Fire, according to their intended Nature; and it is always beſt to give the ſweeteſt to that intended to be the fineſt Malt.

Pale Malt ſhould, for this Reaſon, always be dried either with Coak or Culm, and the firſt is much the beſt.

The Amber may be Straw dried, but 'tis not nearly ſo well. As to the Wood and Fern they are uſed in ſome Parts of the Kingdom, and Cuſtom makes the People reliſh the Beer brewed from ſuch Malt; but to a Stranger there is a moſt nauſeous Taſte of Smoak in it.

The common Practice is to brew ſome one Kind of Malt alone; but the mixing half Brown and half Pale, is a Way to make a very ſound, pleaſant, and wholeſome Drink.

With Reſpect to Waters they may be ranked under four Kinds, Spring, River, Rain; and Pond. We have obſerved that Spring Water is very proper for the pale Malts; but let it be ſuch as is pure. There is a great deal of Spring Water impregnated with various Subſtances, as Salt, Allum, Iron, and the like. All theſe are improper for the common Service of Brewing. Some uſe them indeed for Medicinal Purpoſes, brewing Drinks with them that it may

have their ſeveral Virtues, but this is not what we ſpeak of here. We are informing the Farmer how to brew good Beer, and not how to make Medicines.

River Water is in general the beſt of all for Brewing: but to be in Perfection it ſhould be ſuch as is not near the Head of the River, becauſe that will be of the Nature of Spring Water; nor near great Towns where Filth is thrown in: and to be nice in having it in the greateſt Perfection, it ſhould not be uſed after great Rains when it is thick and muddy.

Clear River Water is ſoft, and the fineſt of all: it is naturally pure, as riſing from a Spring, and it has been ſoftened by its Motion, and by the Effect of the Sun and Air.

River Water in general takes out the Virtue of the Malt better than Spring Water; and the Difference is ſo conſiderable, that about one ſeventh Part more Malt is required to make Beer of the ſame Strength from Well Water and from the other.

Rain Water is the ſofteſt of all; and makes the ſtrongeſt Liquor from an equal Quantity of Malt: but the Beer made from it does not keep well. It is therefore fitter for Ales that are to be drank ſoon, than for Beers that are for Continuance.

Pond Water, when pure, is very good for Brewing, but where Cattle come in and diſturb it, and where there are great Numbers of Fiſh it is never clear. In this Caſe it neither makes a pleaſant Drink, nor takes out the due Strength of the Malt. When Pond Water is in its Perfection it is of a middle Nature between Rain and River Water; but in Places where it is made foul by the before-mentioned Accidents, it is worſe than any.

CHAP. VI.

Of Brewing in general.

THE Farmer having, according to theſe Directions, prepared or purchaſed his Malt, and fixed on a proper Kind of Water for it, is to proceed to Brewing.

His Malt is firſt to be ground, and let him give Orders that this be done moderately. It ſhould be only cracked, and in general ſhattered in the Mill. This is ſufficient, for the Water will in that Caſe thoroughly take out its Virtue; and if it be broke more it will not anſwer ſo well in the Brewing.

Many deſire their Malt to be ground very fine, thinking it by that Means anſwers better in giveing out its Strength; but in this Caſe it mixes with the Water inſtead of impregnating it with its Virtues; and the Wort runs thick, and the Brewing goes on coarſely.

Let the Farmer always have his Malt ground ten Days before the Brewing. This is the moſt eſſential to the brown Malts, becauſe it takes off the fiery Taſte they got in their high drying; but it is of great Uſe to all. The ground Malt muſt be kept in a dry Place, and it always mellows in lying. The paler the Malt the leſs Time it needs lye after grinding. In the London Way of Buſineſs it is not eaſy to give the Malt this Advantage, becauſe they brew ſo frequently and in ſuch Quantities, therefore the Family Brewer has in this Article an Advantage. In general about eight Days may be allowed to the pale Malts, and from ten to twelve or fourteen to the brown.

The Malt thus ground and kept is ready for Uſe, and we ſhall lead our Country Farmer into the Practice, by giving him a general Idea of what is the Method in London, where there are perhaps the moſt underſtanding Brewers in the World.

Four Kinds of Beer are in general brewed in London, Stout, common Butt-Beer, Ale, and Small Beer.

Stout is the ſtrongeſt Beer, brewed from brown Malt; and is ſold for forty Shillings the Barrel, or ſix Pound the Butt, from the wholeſale Cellar.

To brew this, the Water in the Copper for the firſt Marſh is made to heat ſoon, by pouring in a couple of Buſhels of huſky Malt, juſt to ſpread over its Top.

The Degree of Heat to be given this is the utmoſt that the Hand can endure, but it muſt not boil.

When it is in this Condition the Fire muſt be damped, and the beſt Way is by throwing on a good Quantity of freſh Coals. Then cold Water is to be let in till the whole is juſt Blood-warm. The Malt is then to be worked in with Oars, half an Hour, and this is called the Stiff Maſh.

While this is beating up more Water is boiling in the Copper. This is to be let in: and the whole being maſhed again, and well mixed, ſome Baſkets of Malt are thrown over it, and it ſtands an Hour.

At the End of this Time it is let out into the under Back; and is then boil'd an Hour and half. This, with the due Quantity of Hops, is the Stout.

The common brown Ale, or as they call it ſtarting Beer, is made in the ſame Manner as the Stout; but a larger Quantity is brewed from the ſame Portion of Malt. After the ſtiff and ſecond Maſh they cap the whole with freſh Malt and boil it an Hour, and after this Small Beer is made of it. The Difference between brown Beer and brown Ale is only that leſs Beer is made, and it is boiled longer and has more Hops, proportioned to the Time it is intended to be kept.

The pale Beers are brewed in the ſame Manner, only Pump Water is uſed, and it is made hotter at firſt, and lowered to be almoſt cold afterwards.

The Small Beer in London is made thus. They heat the firſt Water with ſome hully Malt over it, and when it is of a due Heat they let in ſome cold, and run it into a Tun Milk-warm. The Malt is maſhed in this; and then the ſecond Quantity of Water is let in, which is ſcalding hot. It is to ſtand an Hour, and then be run off into the under Back.

This makes one Copper of the firſt Wort without putting any freſh Malt in. The next Liquor is to be Blood-warm, then hot, and then laſtly, cool.

This is the great Secret of the LONDON Brewing. Their Beer has a very great Advantage from the Quantity that is brewed together; and there is a great deal of Art in putting in the firſt water Blood-warm, and the Reſt hot: for this warm Water opens the Malt beyond any other Practice, and makes it ready to receive, and yield all its Strength and Virtues to the hot.

The Quantities we have not named in the Courſe of the Brewing, reſerving them for a diſtinct Mention here by themſelves, the Strength alone depending on that Article.

The Allowance for Stout Beer is a Quarter of Malt to one Barrel; and this is ſold from the Tap at thirty Shillings. The Proportion for the common Brown Ale is a Quarter of Malt to a Barrel and Half. For entire Small Beer the Allowance is a Quarter of Malt to ſix Barrels; tho' ſome allow a Quarter to five. The Allowance for Pale and Amber Ale is a Quarter to a Barrel and a Firkin.

Thus have we laid before the Country Farmer the general Proportions and Method of working in the LONDON Brewhouſes for their various Kinds of Drink; and from this general Idea of the whole Art, and the Particulars of the ſeveral Kinds premiſed before, he will be able to comprehend the whole Theory, Art or Myſtery of the Buſineſs, and may ſafely and ſucceſsfully enter on the Practice.

CHAP. VII.

Of brewing for a private Family.

TO ſpeak with Certainty, and in a determinate Manner on this Article, we muſt firſt eſtabliſh ſome regular Quantity intended to be brewed; and ſome regular Size of the Veſſels.

We will ſuppoſe that the Farmer has a Copper, which, when filled to the Top, holds a Barrel, that is, ſix and thirty Gallons; and we will ſay he is to brew five Buſhels of Malt. He has this in the Houſe, it has been ground a proper Time, and there is nothing to be done but to put to it the Water proper of its Kind.

Let the Water be ſet on in the Copper, and when it is pretty hot pour upon it Half a Peck of Malt. This will keep in it Spirit, ſoften it, and purify it, and make it heat regularly. When it begins to boil ladle it out into the Maſh Fat, and there let it ſtand about a Quarter of an Hour.

It is often the Neceſſity of the Farmer to uſe but indifferent Pond Water in Brewing. In this Caſe let him pour Half a Peck of Bran upon it inſtead of the Malt, and when it boils ſkum that off. It will take the worſt Foulneſs of the Water with it; and is to be given to the Hogs. In the other Caſe, when the Water is tolerably pure, the Malt is to be uſed as mentioned already; and this is not to be ſcummed off, but to be ladled out with the Water.

When it has ſtood about the Time mentioned, the Steam will be but little, and the Farmer may look down into it and ſee his Face in it. This is the Country Rule, and it is a very good one; for he cannot ſee it while the Steam riſes thick, as it does from the hot Liquor. Separate Half a Buſhel of the Malt, and let the Reſt run ſlowly and leiſurely into the Liquor when it is of this Warmth; let it be well ſtirred about as it runs in, and ſo mixed when all is together, that it does not lie any where in Cakes or Lumps.

It is a common Practice to beat and ſtir up the Malt in this firſt Maſh into a Haſty Pudding, but this is very wrong: the whole Brewing always ſucceeds better when it is in this Manner only well mixed together without ſuch Beating. It receives the hot Water the more freely and perfectly, and gives Strength to it in a very fine Manner.

When the Malt is thus thoroughly ſoaked, the hot Water is to be ladled on by Bowls full, and it is to be ſuffered to run out at the Tap in a very ſmall Stream, not thicker than a Straw. In this Manner, as the Malt has not been maſhed to Pieces in the Water, the Liquor will run off very clear, and will yet have the full Strength and true Flavour of the Malt, according to its Kind; and will much ſooner be fine than in the common Way of Brewing.

This is the Method to be taken when the Farmer is for brewing a good Ale, and will make his Small Beer ſeparately, or leſs regards it: but when he minds the Small as much as the Strong, the ſecond Copper of Water muſt be poured on quick, and ſuffered to run off in a large Stream. This will make a good bodied and well taſted ſtrong Beer, and yet there will remain in the Malt Virtue enough for impregnating the Small.

When the firſt Stirring of the Malt is done, let the Half Buſhel that was ſaved out be carefully ſpread over it; and then let ſome Sacks, or other Covering, be put over the Tub to keep in the Steam.

The whole is to ſtand in this Way about two Hours and a half, and in that Time the ſecond Copper of Water is to be made boiling hot.

This is then to be poured on either briſkly or ſlowly, as we have directed, according to the Deſign of more or leſs Small Beer; and when it is in, let as much run off from the Tap as will very near fill the Copper.

Put half a Pound of fine ſweet Hops in a Canvas Bag, and putting them into the Copper boil them half an Hour: then take them out; and ſome freſh ones are then to be put in and boil half an Hour. The Quantity of Hops muſt be greater for Beer, and leſs for Ale.

If the Beer be intended for keeping, half a Pound of freſh Hops ſhould be put in every half Hour, and the whole boiled briſkly for an Hour and an half.

While this firſt Copper of Wort is boiling, ſome ſcalding hot Water muſt be poured in upon the Malt, Bowl by Bowl; and thus ſo much is to be got in and ſuffered to run off again, that there may be the Quantity of another Copper ready for boiling, by that Time the firſt Quantity is boiled off.

When this is drawn off the ſecond Running muſt be put in and boiled an Hour, with nearly the

the ſame Quantity of Hops as at firſt; and while this is doing, Preparation may be making for Small Beer, by pouring on ſuch a Quantity of Water as the Farmer chuſes cold upon the Grains all at once, or at twice.

This muſt be boiled up in the Copper in the ſame Manner as the Ale Wort, and muſt have the Hops that were boiled before. Each Copper of the Small Beer ſhould be allowed an Hour in boiling. In this Manner five Buſhels of Malt will make the Farmer a Hogſhead of Ale, and the ſame Quantity of Small Beer; or if he chuſes otherwiſe, his Ale will be much the ſtronger and better.

Each Copper of Wort muſt be ſtrained off through a Sieve, and cooled in four or five Tubs.

The Farmer will find a Hogſhead of Ale in this Manner made from five Buſhels, a very pleaſant and ſound Drink: if he chuſes to make it ſtronger, and for keeping, he muſt boil off only the one firſt Copper for Ale, and the Reſt all for Small Beer; which in that Caſe will be of a very good Strength.

The Farmer will ſee that in this Method, although very different from the LONDON Brewer's Practice, yet all that is valuable in that Art is preſerved. He may, if he pleaſes, imitate their Methods, by putting in more Malt after the ſecond Maſhing; and thus running off, according to his Pleaſure, a larger Quantity of ſtrong or of ſmall Beer: but this is getting into a confuſed and perplexed Practice. The other is plain, familiar and eaſy: and we may affirm upon repeated Experience, that whoſoever follows it, punctually will brew to his Satisfaction in every Reſpect, for the good Flavour and the Strength of his Beer.

CHAP. VIII.

Of the Advantages of brewing at Home.

WHAT we have here propoſed to the Farmer we would recommend alſo to every middling Family; and that for more Reaſons than will at firſt be thought. The Difficulty upon this plain Receipt for doing it is nothing; the Time required is only a few Days in a Year, and the Inconvenience is not much: the Advantages are very many. The ſaving in Money is very near half in half; and the Houſekeeper is ſure that nothing but wholeſome Ingredients have gone into the Liquor, which he never can pretend to know if he buys it of a common Brewer.

Moſt People have been deſirous of brewing at Home, but they have been deterred from it, partly by their thinking there was ſome great Myſtery and Secret in doing it well; and partly that there required a great deal of Room, and a great many large Veſſels, for the brewing but a moderate Quantity of Drink.

We have ſhewn this to be entirely an Error in both Reſpects. The Secret is in a Manner nothing, a few plain Words have deſcribed it; and in this Method which we have laid down, a moderate Copper, and a few common Veſſels anſwer the Purpoſe of brewing a Couple of Hogſheads.

We have only to add on this Head one general Caution, that Cleanlineſs be obſerved in every Thing relating to a Brewery. We have ſhewn the Neceſſity of it in a Dairy, and the Brewhouſe is the next Article to that, requiring it to be obſerved with Strictneſs.

Many who brew at Home, find their Beer that was not at all faulty at firſt, contract ill Taſtes, and grow very bad after a little Time; and they little ſuppoſe how much this may be owing, and how frequently it is, to the Careleſsneſs of keeping the Brewing Veſſels.

In Families where the Brewing comes ſeldom, the Utenſils are laid by careleſsly; and the Conſequence of this, eſpecially if there be any Damp about them, is, that they grow mouldy or muſty.

When Mouldineſs is ſeen, there is a natural Caution for the cleaning it away; but there will be Muſtineſs when there is no Mark to the Eye: and Servants are often ſo negligent, that they ſeem to have the Senſe of ſmelling given them to no Purpoſe.

We adviſe whoever intends to brew at Home, to look carefully himſelf into this Article. Let a Copper of Water, or two if needful, be boiled ſeveral Days before the brewing, and let the ſmaller Utenſils be boiled in it; and the larger well ſcalded with it. Let them all be thoroughly and perfectly cleaned after the Scalding, and then ſcalded again: after this let them be expoſed to the Sun and Air, ſo as to bleach and perfectly ſweeten, but not ſo as to crack them; and after this let them be ſet by for Uſe.

If every Thing be thus conducted, the Malt ſuited to the intended Kind of Liquor, the Water to the Malt, and the Quantity duly proportioned: if the Working be carefully heeded, and the Veſſels clean, there can be no Doubt of the Whole ſucceeding to Credit and entire Satisfaction.

BOOK XI. PART II.

Of CYDER.

INTRODUCTION.

WE have gone through the general Account of the natural and artificial Products of the Farmer's Stock, and might here close that Part of our Undertaking: but as the Husbandman should never be without an Orchard, and as we would have him make every Part of his Ground turn to some Account, we shall advise him to make Cyder from the Produce of his Apple Trees.

Under this Head we are very happy, that we have an Opportunity of communicating to the Publick a Method, of raising this BRITISH Liquor to an Excellence which few know it can reach, and which renders it equal in Value to many Wines. This we receive from a Clergyman; a Gentleman of eminent Knowledge and distinguish'd Candour; and we have Authority to assure the Publick, that it contains nothing but the Result of Experience; that nothing is directed to be done, but what the learned and reverend Author has himself frequently practised, and does at this Time practise; and that the Result is his having Cyder superior to any other Person; and for which he has been offered in Exchange Quantity for Quantity of very valuable Wines.

As this is a Method never published, and the Account in some Parts refers to Things commonly known in the Cyder Countries, though they may be strange to the Reader in general, we shall prefix to it an Account of the usual and received Way of making this Liquor.

Those who chuse to practise the old Method, will therefore in this Place have full Directions for doing it; and those who shall follow our Advice, and attempt it upon the Rules prescribed by this valuable Correspondent, will, by having gone through the other Account first, perfectly understand every Process and every Part mentioned in this.

It is proper, in order to trace this Subject from the Beginning, to instruct the Farmer in this Place to plant his Orchard rightly. This falls very well in with our Plan in the present Work, the Intent of it being to instruct the Farmer in every Part of his proper Occupation. This is indeed a Subject we shall hereafter pursue through all its Branches, being determined to publish, after this Work is finished, a Compleat Body of Gardening in the same Form. The specious Appearance of other Works already extant under the like Names, is to us no Discouragement in this Undertaking; because partly the Papers in our Possession, many of which we find relate to Gardening, and partly our own Experience, have shewn us, that the most popular of those Works abound with Errors.

The same Hands which have compiled this Body of Husbandry, intending therefore to continue their Labours with the same Assiduity, to finish from the like Materials and the like Experience a Body of Gardening, we shall not on other Articles, confound or perplex the Reader, by mixing together two Considerations so naturally separate; but shall reserve to that succeeding Work what Directions we have to give with respect to planting Fruit Trees of other Kinds. Here we shall treat only of the Apple; and under that Head, in the usual Course of our Work, and according to our accustomed Method, we shall first teach the Farmer to plant an Orchard, and bring it to a bearing Condition: we shall then direct him, according to the usual Practice, to make the Advantage of Cyder from his Fruit; and afterwards lay before him these new discovered Methods for improving that Liquor.

CHAP. IX.

Of chusing a Spot for an Orchard.

ALL that we direct the Husbandman to practise is, with a View of Profit. His Orchard we do not look upon as an ornamental, but useful Part of his Concern: and far from limiting it to the trifling Services of the Fruit at his Table; we intend it as the Source of very considerable Advantage in the Article of Cyder, which we shall give him the usual Rules for making, and afterwards these others, hitherto unpublished; which are vouched upon the most certain Authorities, Experience, and the Testimony of others of Knowledge.

If the Husbandman finds an Orchard upon his Farm, tolerably planted, and in a good State of Growth, he is to make the most of it in the Way we shall direct hereafter. If there be none, let him by all Means plant one; if he be fixed for a Continuance: and let the Land Owner never omit that Article. When the Orchards already planted begin to decay, this will be very well worth his while; and we shall here lay down the most profitable Method of doing it.

The first Consideration in the raising of an Orchard, is the Choice of a proper Piece of Ground. It is a Plantation that is to continue a great while, and that may be of very great Value hereafter, it is therefore worth while to be careful. 'Tis most convenient to be near the House, for the Advantage of gathering the Fruit, and for its Safety from their being stolen: but if there be not a proper Piece of Land near, it must be chose farther distant; for 'tis to no Purpose to have Convenience or Security where the Trees will not thrive.

Different Kinds of Ground will suit different Fruits; and if such a Soil as is suited to the particular Kind intended to be raised be not first carefully chosen, all the Expence and Care that

ſhall follow will breed only Diſappointment.

Let it be conſidered that Trees root deep; and accordingly let the Huſbandman extend his Regard to the Nature of the Ground, farther than to what appears towards the Surface. Of all Soils for an Orchard intended for Cyder Apples, there is none comparable to firm, rich Loam.

As to what lies under it, let the Huſbandman ſee that it be not a cold, tough Clay, nor a perfectly barren Gravel. Any other Bottom will anſwer, but in neither of theſe Caſes the Trees will ever thrive. In the Caſe of a tough Clay Bottom, the Roots will always be chilled, and the Branches covered in the Moſs: in Caſe of the barren Gravel, their Barks will crack or peel, and the top Branches will wither and ſhew what all the reſt ſuffer tho' leſs viſibly, that they are parched and ſtarved for Want of Nouriſhment.

The Depth of the good Soil is a very material Article, for Trees ſpread out Multitudes of Roots ſideways near the Surface; and the extreme Parts of theſe will fill all the good Soil be its Depth what it will: it is therefore of the utmoſt Importance that they be well ſupplied with Nouriſhment.

The next Article to the Soil is the Situation, for this is of great Conſequence; and he is happy who finds the Advantages of both together.

An Orchard ſhould neither lie on a Flat, nor upon the ſteep Edge of a Hill: if it lie in a perfect Flat the Roots will be chilled by too much wet, and it will want the Advantages of Sun and Air which higher Situations enjoy: and on the other Hand, if it be planted where the Deſcent is too great, little Wet will lie for the furniſhing the Roots, and the beſt Part of the Soil will be waſhed away from them.

For theſe Reaſons, the proper Piece of Ground for this Purpoſe is one that has a gentle Riſing: here the Sun and Air have free Paſſage among the Trees, and enough Wet will lie for the Benefit of the Growth, but not enough to do Hurt. In the abſolute Flats too much Wet lodges, the Conſequence of which is the chilling of the Fibres, if there be no Sun to evaporate it; and if there be 'tis often worſe, for the Quantity makes the Air foggy, and is the Occaſion of Blights and many other Miſchiefs; as we ſhall ſhew when we come to treat of that Matter.

Let the Huſbandman therefore underſtand, that if he can find near his Houſe a Piece of Ground that has a gentle Aſcent, where the Soil is a rich, deep Loam, and the Bottom neither is a cold Clay nor a bare Gravel, he is very happy in a Piece for an advantageous Plantation.

There are certain Advantages of Shelter from bleak Winds, and Openings to the milder Air, which that Piece of Ground is always to be valued that has; but as this may always be given by a proper Plantation, let the Huſbandman be ſure, that if Nature has not given it, his Care and Induſtry do. The North and North Eaſt Winds are thoſe which will be moſt miſchievous in the Spring, and very frequently a North Weſt in a more advanced Growth does great Damage; therefore let him plant in ſuch a Manner about his Orchard, that it be perfectly defended from theſe Quarters, the North, the Eaſt, and the Weſt; let it be open to the South to let in the Sun: and when all that is hurtful is blocked out, and all advantageous admitted in his Plantation, which before had all the Advantages of Soil and Situation, it will alſo have thoſe of Sun and Air.

The Trees that are to defend the Orchard will grow up with the others, and all will thrive as they ought; only let the Planter in this, as we have warned him on all former Occaſions, be careful not to run into one Diſadvantage by his Earneſtneſs in avoiding another: his Orchard is to be defended, but it is not to be blocked up. We have ſhewn the Diſadvantages of this to all Growths whatever; and it is in none ſeen more than theſe. While the Winds are kept off, there muſt be a clear and free Paſſage for Air; or all will come to little. This is to be obtained by planting the Trees intended for Shelter and Defence at proper Diſtances, and trimming them in a judicious Manner as they grow; leaving on Branches enough to break the hurtful Winds, yet not ſo many as to choak the Paſſage of the Air. The Fruit Trees themſelves muſt be planted alſo with a careful Regard to this Advantage.

CHAP. X.

Of diſpoſing the Orchard.

WE now enter on a Point leſs underſtood and worſe practiſed than any Thing in the Huſbandman's Profeſſion; but we ſhall endeavour to lay down ſuch Rules as will lead him into a better Tract. Let him obſerve, that we have ſaid a free Paſſage of Air is of the utmoſt Conſequence; it muſt have Liberty to go briſkly between Tree and Tree, and to carry up all damp Vapours with it, elſe they will deſtroy the Hope of the Planter. Let him firſt take Care of this in the planting his Timber Trees for Defence. If there be riſing Grounds towards the North Eaſt and Weſt, they will defend the Orchards without other Help; and when they are wanting, let him plant his Trees for this Purpoſe far enough from the Fruit Trees, that they be not choaked up by them.

The ſame Caution is to be obſerved, that the Fruit Trees do not choak one another. Moſt Orchards are planted much too cloſe. The Deſire of having a great deal of Fruit upon a little Ground is the Cauſe of this, but the Method they take defeats the Purpoſe. They do not conſider when an Apple Tree is planted to what an Extent its Branches will ſpread, or how far its Roots will run in the Ground. Let our Huſbandman take Care of this; let him give Compaſs for the Roots that the Trees do not ſtarve one another, and free Air Room for the Boughs, that there may be clear Space enough between thoſe of the ſeveral Trees at their utmoſt Growth for a Paſſage of the Air, Sunſhine and Winds.

We have, on many other Occaſions, ſpoken of the great Folly of cloſe planting, but in theſe Trees it is worſt of all: they ſpread farther, and they are to ſtand longer than others, ſo that 'tis an Error not to be remedied. We ſhall aſſure our Farmer, not on Reaſon only, but a careful Examination, that of the Orchards in general in moſt Parts of the Kingdom, if the Trees were but half as many, the Fruit would be a great deal more than it is from the whole. The natural Vapours of the Earth being pent up among cloſe planted Trees will occaſion Blights: but that is not all; the Perſpiration of the Trees themſelves is very great, and that joined with the Vapours from the Earth, will at the ſame Time hurt the Growth, and give an ill Taſte to the Fruit: the Sun is a very eſſential Thing for the raiſing a Cyder Apple to its right Flavour, and that is not to be had where the whole is kept in Shelter by the Covering of the Boughs.

The Huſbandman who has an old Orchard will do well to thin it by cutting away a great deal of the Heads of his Trees, that the Air may paſs more freely; but in the planting a new one, another Sort of Caution ſhould be uſed, for it is better to prevent than remedy.

We ſhall ſhew the Farmer that he would loſe leſs Ground by planting his Orchard very diſtant than ever ſo near. In the Common Way of near planting all the Ground is loſt for other Purpoſes; whereas, if the Trees be ſet at great Diſtances, it may be tilled as other Land, and will produce Crops in the ſame Manner; and theſe, far from impoveriſhing the Trees, will, by the Culture of the Ground, cauſe them to grow quicker, to flouriſh more in every Reſpect, and to laſt longer. We have explained in treating of the Horſehoeing Huſbandry, the vaſt Advantage of tilling the Ground while a Crop is upon it. This is a Benefit Trees will ſhare in common with other Growths; and what we are now propoſing is with Regard to them in all Reſpects the raiſing them by the Horſehoeing Huſbandry. The ſlight rooting Crops of Corn ſown in the Ground between them do them very little Harm, and the breaking and dividing the Land by Tillage for theſe Crops enriches them prodigiouſly; ſo that the Advantage is many Times greater than the Damage.

This then is the Plan upon which we adviſe our Farmer to begin his Plantation. He has choſen a Piece of Ground of proper Condition, and of ſufficient Extent: it is defended properly, and yet open to the beſt Influences of the Air. All this ſerves for the Advantage of the Corn as well as the Trees; and let him conſider the Piece therefore as a Quantity of arable Land as well as an Orchard. This Caution only is to be given him, that he ſow upon it none but the ſlight and ſhallow rooting Crops, as Corn, the Pulſes, and the like: for the others would interfere with the main Deſign, and be every Way improper.

His Ground being thus choſen, let him make a Plan of it upon Paper, and mark the Places of his Trees. Let him diſpoſe them in regular Rows; and let theſe Rows be thirty Yards aſunder; and the Trees twenty Yards from one another in the Rows.

Such a Plantation will have all the Advantages an Orchard poſſibly can enjoy. It will bear as much Fruit as it will be poſſible by any Art to obtain from an equal Quantity of Ground; and all the Time the Farmer will have the Benefit of it as ſo much Land like the Reſt. In the firſt Year every Foot of it will bear as well as any other Ground; and when the Trees are fully grown, he will only loſe the Advantage of a ſmall Spot round each, which therefore it will be prudent in him not to ſow: the Ground will all bear, except juſt under the Shadow of the Boughs.

CHAP. XI.

Of making the Plantation.

THE Farmer having thus eſtabliſhed in his own Mind, what is beſt for the planting his Ground, and to avoid Forgetfulneſs or Miſtakes, having drawn the Plan of his intended Orchard on Paper, which indeed it requires no great Skill to do, he is to proceed to put this in Execution.

We will ſuppoſe it Spring, and the Ground he fixes upon to be a Piece that is in Paſture: let him not count ſo much upon the Profit of the Summer's Graſs, as to defer the Work till it is got in or eaten off; this is a ſmall Advantage in Proportion to what he is about. Therefore early in the Spring let him plow it up, turning the Turf in that it may rot. Three Times in the Summer, at equal Diſtances, let it be plowed over again, to break and divide the Soil, to tear the Turf to Pieces, and to prevent the Growth of Weeds. The laſt of theſe Plowings ſhould be toward the End of SEPTEMBER; and this ſhould be a very deep one, that the Ground may be prepared for the Reception of the Trees.

There are two Seaſons for planting the Trees, and the Farmer ſhould take no certain Reſolution in Favour of one or the other; but be guided by the Weather, and the Nature of the Ground.

If the Soil be dry, and the Autumn favourable, any Time in OCTOBER the Trees may be put into the Ground: but if the Weather be extremely rainy, and eſpecially if the Soil be inclined to Wet, then the beſt Seaſon is the ſecond Week in MARCH.

As to the Choice of the Trees, the great Article regards their Age: for in this many have run into a very material and very miſchievous Error, by the planting them too large. It is certain, that an Apple Tree may be removed when of a conſiderable Growth, and that it will bear very well after it; but it will neither bear ſo well, nor continue ſo long, as when planted young.

The beſt Age of a grafted Apple Tree for planting as a Standard, is at three Years from the grafting; and for this Uſe they ſhould always be choſen upon a Crab Stock, for none is ſo laſting.

Let our Farmer examine the Ground from whence he has them: by no Means let him take them from a better Soil than his own: if he can have his Choice, let them be ſuch as have ſtood

on

on a Ground like his, but not ſo rich: their tranſplanting them will be natural, and they will at once take to the Land, and thrive apace in it.

Let a Stake be ſet up at every Place where a Tree is to be planted, and a large Hole opened for its Reception: let the Earth that is thrown out be well broken, and laid ready to put in when the Tree is ſet. A great deal of Hurt is done in theſe Plantations by the Holes not being made large enough, and by the Earth being thrown in careleſsly: when that is large, and the Ground that fills it is well broken, and is ſpread regularly, and ſettled by a gentle Watering, the Tree roots itſelf at once, and grows without any Check from the moving.

It is always beſt, when it can be done, to buy the Trees from a Nurſery at a ſmall Diſtance from the Place where they are to be planted, that they may not ſuffer by being kept long out of the Ground: and on all Occaſions the more Expedition is uſed in planting them the better; for they get Harm by the Air coming to their Roots.

When the Trees are thus brought into the Ground, one is to be laid by the Side of each Hole; and both the Roots and the Heads are to be pruned before they are put in: the beſt Way is to prune the Roots as the Tree lies, and the Heads as ſoon as it is planted: for the treading about the Roots in doing this afterwards, and the gentle ſhaking it gets in the handling, help to faſten and ſettle them, and the watering coming on upon that compleats it effectually.

In the pruning of the Roots the firſt Care is to look if any be bruiſed or injur'd in the taking up or Carriage; ſuch are to be cut off a little above the bruiſed Part: after this let the Courſe and Manner of growing of thoſe which are left be examined: it often happens that they croſs one another, cruſh one another, and are thus very hurtful: in this Caſe one of the two muſt always be cut off juſt above the Place; and when the larger Roots are thus regulated, the Fibres muſt be pruned. Theſe muſt all have their Ends cut off; and it ſhould be done juſt before the putting them in the Ground, for the Air always takes an Effect upon theſe ſlender Parts very ſuddenly.

If there be any decayed, mouldy or rotten Roots, they are to be cut off in the ſame Manner; for it is a Damage that ſpreads, and will infect the ſound ones.

All being thus ready, let ſome of the fine broken Mould be ſcattered in the Bottom of the Hole, and the Tree ſet on it perfectly upright, and not too deep: then let the Reſt of the Mould be thrown in a little at a Time, and the whole laid level and ſmooth at the Surface, when every Part of the Cavities between Root and Root has been filled up.

The Tree is now in the Ground, and the Head is the next Care. In old Time in ENGLAND Gardeners were afraid of taking off the ſmalleſt Shoot from a new planted Tree: at preſent the Faſhion is oppoſite; the Gardener with his Knife is as terrible as the Surgeon with all his Apparatus of Inſtruments; and he thinks the more he cuts away the more he ſhews a maſterly Hand: both Extreams are wrong. Indeed what Extream is not!

The new planted Tree will not be able to ſupport ſo large a Head at firſt Setting, as it did while in the native Ground: but on the other Hand, if ſome be not left on, it cannot thrive. We have before acquainted the Huſbandman how eſſential Leaves are to Trees; and he will therefore plainly ſee the Folly of cutting them all off with the Branches.

What he is to do is to take off a Part, and to manage his Knife in ſuch a Manner, that what is left on may be of ſuch Growth as to form a well ſhaped Head.

When the Tree is thus planted upright, and reduced to a proper Shape and Size in the Head, it is to be ſecured from Damage by Winds by ſtaking. To this Purpoſe a ſtrong Stake having been driven down near each Tree, the Stem is to be tied to it with a Hayband, or ſome other ſoft Subſtance, that will not hurt the Bark.

This done, the Plantation is ſecure: the Huſbandman is to till the Ground between the Trees. They will grow up without his Care if the Seaſons favour them; if not it will be proper for him to water them at Times, both the firſt and the ſecond Year. The new Plantation will be ſtarved by being left too dry; but there is no greater Miſtake than the watering them too largely. In the firſt Caſe the fine and ſmall Roots ſhrivel up and wither; and in the latter they are all rotted by the Abundance of Wet.

We have ſpoke of laying Sones about the Roots of new planted Foreſt Trees, to fix them and to keep the Ground moiſt; but we ſhall here propoſe a better Method for theſe Plantations.

Let there be a good Parcel of Turf pared pretty thick from a Common, and brought freſh into the Ground, and let a Quantity be laid down by the Foot of every Tree. Let a Labourer carefully ſpread this round the Bottom of the Stem, laying the Turf Part downards, and then covering the Ground with it two Foot each Way from the Tree. This needs not ſet aſide the Uſe of watering, for it will make it anſwer much better, becauſe the Moiſture will be detain'd as long as it ought; and this Turf may be afterwards dug in as a Manure. This Kind of Plantation we ſhall explain in a Folio Plate, at the Cloſe of our Directions concerning Cyder.

CHAP. XII.

The general or common Method of making Cyder.

WITH Reſpect to the Choice and Kinds of Apples, their Mixture and peculiar Management, we ſhall refer the Reader to the ſubſequent Chapter: We are not here entering into Particulars, but delivering only the general Method, and univerſal Rules; that the Proceſs of Cyder making may be underſtood in itſelf, and conſequently the following Account be underſtood without Heſitation.

The Apples intended for Cyder muſt be picked clean, and their Juice expreſſed or ſqueezed out. The picking them is an eaſy as well as a needful Article; no Filth or Foulneſs

of any Kind must be mixed with them; and if there be any decayed ones among them they must be thrown away.

The picked Apples are to be put into the Mill, where they are mashed and ground to Pieces by a Stone moved round upon them: this is the proper Method for large Quantities; but any Method of bruising and squeezing them thoroughly will do.

The Juice of the Apples being thus squeezed out, is to be caught in proper Vessels, and as some Foulness will have come among it, it must be strained. A tolerably close Hair Sieve answers very well for this Purpose, or a Canvas Bag may be employed, or any other Contrivance that will let the Juice run freely through; and keep back the gross Particles.

The Juice thus strained from Impurities is to be put into a Vessel, which must not be quite full. It is to be covered loosely, and set quietly by for three Days.

At the End of that Time it is to be covered up as tightly and closely as may be with Clay; and then the Business is to watch for its growing fine.

This is to be known only by trying from time to time. To this Purpose a small Quantity is to be drawn out once in a Day or two, and examined in Point of Clearness. When it is sufficiently clear, it is to be pierced for a more certain Examination of the whole.

In this Respect we are to inform the Farmer, that he is to consider his Cyder according to the Nature of the Apples under three Kinds. These may be named according to the Apple; 1. The Summer Fruit Cyder; 2. The Gennet moil Cyder; and 3. The Redstreak Cyder. These have their three several Times at which they may be naturally expected to arrive at this Degree of Fineness: the Time of the Summer Fruit Cyder is about a Month: the Gennet moil Cyder seldom comes to it till toward the Beginning of October; and the Redstreak Kind not till January.

These are not to be supposed certain, invariable, and universal Rules, for there can be none such. The Weather, the Temperature of the Air, and the Degree of Ripeness of the Fruit, all these singly, and two or more of them together, will naturally make very great Variations. Sometimes a Quantity of Cyder will be fine sooner than could be expected: frequently it takes a Fortnight longer for the Summer Fruit Kinds, and a Month or six Weeks longer than the natural and usual Time for the others.

In general the Winter Fruits of all Kinds are to be expected to answer in the Manner of the Redstreak, and when after a Month, or at the utmost six Weeks more than the usual Time, they are not grown fine, they must be racked off as clear as may be in the Manner of Wine.

Many Expedients have been used to fine down the Cyder that does not answer as it should, but most of them are very improper. There is however one eminent Ingredient, that is of excellent Service to this Purpose, and may be used with perfect Safety. This is, Isinglass. It is a very harmless Drug, and when dissolved is of such a clammy Quality that it lays hold of all Kinds of Foulness; and when the Fault is not too great will carry all down with it, and leave the Liquor perfectly fine.

As we have named this Ingredient, we shall inform the Farmer how he is to use it, for there is nothing so generally mistaken. Isinglass is brought from the Northern Parts of Europe, where it is made by boiling the sinewy and skinny Parts of a Fish, much like a Sturgeon, to a Jelly; which is then poured out upon a Table to dry, in the same Manner as our Glue is made.

The common Method of the Country is not to cut it out into flat Cakes, as we do our Glue, but to roll it up into long Pieces, which they double together in the Shape of an Iron Staple.

This is the Shape in which Isinglass comes to the Druggists, and they are ready enough to sell it in this Form: but this is not the Way the Farmer is to buy it. These large Lumps are very hard to dissolve; but when it is beaten out into thin Shivers, it will melt in any Liquor that is not too strong, without much Difficulty.

Water dissolves it best, because it has been boiled up in Water; but this is not the right Method for Cyder, because the Addition of any Water will impoverish the Cyder, and therefore have a just contrary Effect from the fining of it; any thing that weakens a Liquor of this Kind naturally rendering it cloudy.

For this Reason the best Way is to dissolve the Isinglass for the present Purpose in a good bodied white Wine. As this is a stronger Liquor, the Isinglass will not melt so freely in it, therefore there is the more Occasion to buy it in a proper Condition. Let the Farmer who wants this Drug therefore, see that he ask for beaten Isinglass, and that it be well beaten into thin Shivers. Then he is to put it into the Wine for fining down the Cyder.

It will be fit for Use as soon as it is thoroughly melted, but not before: this is a thing that is done slowly: some hasten it by Heat; but that is not so well. If the Wine and Isinglass be set over a gentle Fire, and kept stirring, it will in some little time melt; but thus the Wine loses a great Part of its Spirit, and often the whole gets a burnt Taste. This is to be guarded against in the most careful Manner; if the Necessity of the Farmer's Affairs make him use the Way with Heat: but the better Way is to take a proper Time, and let it dissolve in the cold.

The fine beaten Isinglass is for this Use to be put into a large Bottle, two thirds filled with Wine; and set by in a Cellar. It is to be shook gently from time to time, and by Degrees it will perfectly dissolve, and the whole will make a fine Jelly. This Dissolution is much more perfect than that with the Help of the Fire, and it always succeeds much better when put to Use.

When the Cyder is thus made fine by an innocent Addition, or when it has, in the common Course of Time, become fine of itself, it is to be drawn off at Pleasure and bottled, if the Farmer chuses.

This is the common Rule for making Cyder, and by this the Reader who had not before been acquainted with the Subject, will know the Nature of the general Practice. This being premised, we shall give the Reader the new Improvements of the Gentleman we have before mentioned.

CHAP. XIII.

The Reverend Mr. GEORGE TURNER'S *Method of making Cyder.*

AS we are here about to preſent the Reader with a compleat Treatiſe on this uſeful Subject, obtained from its Author at ſome Expence; and as we hope very well worthy the Publick Attention, it may not be improper to prefix to it what we have been informed concerning its Contents.

The firſt Notice we received of this Treatiſe was in a Letter from Mr. PENROSE, of PENRYN in CORNWAL.

This Gentleman acquainted Mr. OSBORNE, one of the Proprietors of this Work, that Mr. TURNER, Clergyman of that Neighbourhood, greatly reſpected for his Learning and Integrity, had written ſuch a Treatiſe from his own Experience; which he apprehended might be procured for the Service of our Undertaking. Upon this Gentleman's acquainting the Proprietors farther, that the Author had lived many Years in the SOUTH HAMS in DEVON; that he had great Experience in the Subject, and his Rules, ſo far as they had been communicated to the Cyder-makers, had been greatly approved and followed; and that the Treatiſe itſelf, though never publiſhed, had received the Approbation of the late great Doctor MEAD, and had, at his Recommendation, been read before the ROYAL SOCIETY, and univerſally approved; he was requeſted to obtain it from the Author on any reaſonable Terms, that a Piece of ſo eſtabliſhed and authenticated Credit might not be loſt.

In Conſequence of this Commiſſion we have been favoured with the Eſſay, which we here deliver to the Publick as it comes to us, with this additional Recommendation, that the Author of it, who lived fifteen Years near TOTNESS, and had always the Reputation of making the beſt Cyder there, had ſince his Removal into CORNWAL introduced his Method ſo happily, that the Cyder of that County, which never had been of any great Credit before his coming thither, is now advanced to ſuch a Degree of Perfection, that the DEVONSHIRE People, of the moſt famous Cyder Places, acknowledge they have none equal to it.

We have the Pleaſure to receive alſo with the Treatiſe this farther Teſtimonial of its Worth, that the Right Honourable the Lord EDGECUMBE, Mr. HOBLYN, and many other Noblemen and Gentlemen of diſtinguiſhed Knowledge, who had read it in Manuſcript, were deſirous it ſhould be printed for the Publick Good.

To theſe Teſtimonials of the Worth of the Piece, we have only this to add, that it is publiſhed entire, at the expreſs Inſtance of the Author. We ſhould have given the Reader only the practical Part of it, according to the Nature of this Work; but the expreſs Condition on which we received it was, that it ſhould be publiſhed exactly from the Manuſcript, without Addition, Diminution, or Alteration. We did not think it juſtifiable to deprive the Publick of a Piece recommended to us under the Countenance of ſuch great Names, on any ſcrupulous Strictneſs of that Kind; and having accepted it under this Condition, we have no Right to violate the Engagement.

The Treatiſe follows literally from the Hand Writing of the Author.

Engliſh Liquors beſt ſuited to Engliſh Conſtitutions:

OR,

An ESSAY on CYDER.

Directing how to order the Fruit: how to make, manage, and improve the Cyder to the beſt Advantage: how and when to Bottle it: and even how, and when, to drink it too, for Health as well as Pleaſure.

By GEORGE TURNER, *A. M.*
Vicar of MILOR, in the County of CORNWAL.

PREFACE.

THE Rules laid down in the following Eſſay, for the Management of Cyder, have received the Approbation of an Honourable Society; as being founded on Nature, Reaſon, and Experience.

Although I have no Right to mention the Name of the worthy Member, who recommended this Eſſay to the Notice of that learned Body: yet I cannot conceal, that he ſtood, for many Years, at the Head of the Profeſſion of Phyſick, and even to the Time of his Death. As the Rules themſelves were at firſt drawn up at that Gentleman's Command, (for I took his Requeſt to be ſuch) and almoſt in the ſame Form of Words, in which they are now preſented to the Publick: ſo that induced me to borrow ſo many Alluſions from the Practice of Phyſick. What Miſtakes I might be guilty of in touching upon the Medicinal Art; I had received ſuch Marks of Friendſhip from him, as gave me fair Hopes of being entitled to his Correction. And I am ſtrongly convinced, from repeated Obſervations in both Kinds, that the Fermentation and Cure of Cyder cannot be better illuſtrated, than by ſome particular Symptoms diſcernible in Human Bodies.

But its being manifeſtly calculated for the Benefit of my Native Kingdom, is that which hath rendered this little Treatiſe on Cyder acceptable to ſome others of my judicious Friends, as well as to the Gentleman above: for as their Hearts are entirely Engliſh: *ſo they would no more conſent that the Health of their Countrymen ſhould be impaired by* French *Liquors, than that their Underſtandings ſhould be ſubjected to a* French *Religion.*

As for thoſe who are already captivated, both in Body and Mind, and who will ſwallow French *Brandy in ſpite of their Experience, as they do* French *Principles in Defiance of their Reaſon, I do not pretend to reclaim them: their Conſtitution, in each Capacity, is broken, and they are paſt a Cure. The Sight of Multitudes dropping into their Graves, through an immoderate Uſe of ſtrong Spirituous Liquors, can no more convince them of their pernicious Quality, than they can be perſwaded of the monſtrous Abſurdity of Tranſubſtantiation itſelf; which goes down ſmoothly with them, even againſt the palpable Conviction of their own Senſes.*

But

But let ſuch Soakers be upon their Guard: for they can no more blame the FRENCH *Merchants for ſmuggling their Brandy, than they can find Fault with our* ENGLISH *Apothecaries for vending Arſenick. It is a Branch of the Buſineſs of both: and if ſome get their Death by an indiſcreet Uſe of that whereby others procure their Livelihood, the Fault is entirely their own. If they will continue to drink Brandy in Spite of Fate, when they are aſſured that an immoderate Uſe of it is perfect Poiſon; their Bane is of their own ſeeking, and they muſt take the Blame, as well as the Harm, to themſelves. They fall an unpitied Sacrifice to their own Folly; and become the Jeſt and Deriſion of thoſe who ſlily furniſhed them with Materials for their Ruin. For as the County of* CORNWALL, *by running out into a narrow Peninſula betwixt two Seas, doth not afford us any conſiderable Rivers; ſo the* FRENCH *very merrily, but ſarcaſtically, retort upon us for the frequent Cargoes of Brandy they furniſh us with: that they know not what Uſe we can make of ſuch a vaſt Profuſion of that Liquor every Year; unleſs it be to drive our Corn, and ſtamping Mills with it for Want of Water. That I might take an innocent Revenge upon them, the Deſign of the following Diſſertation is to rectify the Manners of my Countrymen, as well as to cure their Cyder. To convince my Neighbours of* CORNWALL *in particular, (who lie moſt expoſed to Danger) that they ſacrifice every thing valuable, (their Health, their Wealth, and their Reputation) to the Whim of an ungovernable Appetite. That Providence* hath been vaſtly kind to us; and that we want nothing but Innocence and Temperance, to render our Lives as happy and comfortable, as they may thereby become long and durable. That the Liquors of our own Growth, and the Juice of the Apple in particular, if well managed, would ſuperſede the Uſe of foreign† Wines, and prove more conducive to Health than any of them.*

If this Eſſay hath its deſired Effect but upon the two Weſtern Counties of CORNWALL *and* DEVON, *I ſhall be content, for their Sake, to draw the Diſpleaſure of the whole Kingdom of* FRANCE *upon me; eſpecially at this favourable Conjuncture, when the whole Navy of* ENGLAND *ſtands ready to guard and defend the Rights of* GREAT-BRITAIN *both at Home and Abroad.*

Milor, January 29. 1756.

* Rejoice, O BRITAIN, ſever'd from the World
By Nature's wiſe Indulgence. Indigent
Of nothing from without; In one Supreme
Entirely bleſt; long may he reign!

†—— Choice Nectar, on which always wait
Laughter, and Health, and Care-beguiling Wit,
And Friendſhip, chief Delight of humane Life!
What ſhou'd we wiſh for more; or why in Queſt
Of foreign Vintage, inſincere, and mixt,
Traverſe the extremeſt World, when native Land
Imparts from bounteous Womb annual Recruits
Of Wine delectable; that far ſurmounts
GALLICK or LATIAN Grapes. And ſhall we doubt
T' improve our vegetable Wealth? which will ſupply
What frugal Nature aſks.——

Mr. PHILIPS's Poem on Cyder.

1. IN the Improvement of Cyder the firſt Rule to be obſerved is, that all the Apples be permitted to drop from the Tree; that they may have the full Benefit of the Stock on which they grew, and of the Sun their Foſter-Father: for by ſtriking down the Fruit before it is ripe, the Buds are ſtruck off with it, the Tree is injured, and the Cyder that is made is tart and harſh, for Want of Time to meliorate the Juice.

2. Let your Apples (eſpecially in windy and tempeſtuous Weather) be gathered up once or twice a Week, and thrown together in ſome ſecure Place without Doors; for hoarding the Fruit in a Houſe is apt to give the Juice a muſty Taſte, for Want of a free and open Air. It alſo prevents the Cyder from quick refining, by rendering the Juice flat, dead, heavy and unapt for Fermentation.

3. Let your Apple-Heap be made on ſlanting and open Ground towards the South, that the falling Rains may fleet from it, and that your Fruit may be expoſed to the Eye of the Sun.

4. To erect a ſlight Covering of Reed over the Apple-Heap, ſupported by four tall Sticks, will be very proper; the fore and higher Part of the Covering fronting the South. By the Shed ſo contrived and ſituated, your Fruit may at once have the Refreſhment of the Air, be defended from Rain, and be alſo viſited by the Sun. But let the Bottom of the Apple-Heap be covered, or paved with broad Stones, and edged round with the like Sort, to keep the Fruit clean and cloſe together.

5. Let your Apples lie in the Heap a longer or ſhorter Time, according to the Nature of them. Mediates, for Inſtance, being of a hard Kind, and their Juice auſtere, do require a Month in the Heap, or more: whereas White-Sours, being of a ſofter and more early Sort, a Fortnight, or leſs, for them may be ſufficient. But the Time for each muſt be proportioned to the Ripeneſs of the Fruit, and to the various Diſpoſitions of the Air and Weather. For, according to the Quality of the Fruit, and the Temperament of the Air, the Apples run ſooner or later to Decay.

6. When your Apples are pounded, let the Muck lie a Day before it is ſqueezed. It will improve the Colour of your Cyder, and render it of a deeper Complexion.

7. If you make a Tun of Cyder at one Time, and have a Veſſel large enough to contain it all, it is a good Way to keep it together: that it may all become fine at the ſame Time, and be fit for racking.

8. When your Cyder is fine, (which it ſometimes happens to be within a Day or two, eſpecially upon a dry, * Northern, or Eaſtern Wind) then, by a Cock placed within half a Foot of the Bottom of the Veſſel, always allowing Room for the Dregs to ſettle in; it muſt be racked off into Hogſheads.

* *The hoary Froſts and Northern Blaſts, take Care,*
Thy muddy Cyder to refine, and drive
Precipitant the baſer, ropy Lees.

PHILIPS.

But

But although Cyder be rack'd never so fine at first, it will ferment again and become foul, especially in rainy and tempestuous Weather, and upon southern and western Winds; (just as the Humours in a Man's Body are set on float, and put in Motion when the Winds are in the same Position; and therefore Laxative Potions are wont to be administered at such critical Conjunctures) and then your Cyder may require several Rackings before you give over your Care about it: for all wet Seasons are injurious to new Cyder, by causing a constant Fermentation for a Month or six Weeks, and longer too, if the rough Winds and foul Weather do so long continue. You must therefore be very observant of them, and watchful against them, by frequent racking, whether your Cyder be fine or not; in order to prevent its over Fermentation, and to keep it quiet.

9. Let this be a standing Rule for your first racking: namely, to set about it when the thick, red Head, or Crust, which covered the Cyder, (like a Mantle upon a Patient under a Course of Physick) that so by its kindly Warmth a Fermentation may be promoted, begins to separate, and white Bubbles do appear. For although your Cyder be foul at that very Juncture, it is yet very proper to rack it: otherwise your Cyder (like a Man wasted by an incorrigible Diarrhœa, or a violent Super-purgation) may become incurable: for it will then (especially in wet Weather) instead of a gentle Fermentation, be put upon the Fret, and (in the SOUTH-HAM Phrase) sing; the wild Notes whereof may be heard at a considerable Distance) till it becomes * pale, thin and languid; and (like the Swan) hath sung itself to Death.

* *Cyder of pallid Hue declares the same*
Devoid of Spirit: wretched he that quaffs
Such Wheyish Liquors. Oft with Cholick Pains,
With pungent Cholick Pangs, distress'd he'll roar.
And toss, and turn, and curse th' unwholesome
Draught.

PHILIPS.

A critical Racking, therefore, is like a critical Bleeding in a Fever; or a well-timed Cathartick, Emetick, or Clyster in a violent Fit of the Cholick; and both the Liquor and the Patient are preserved by Evacuations adapted to their respective Disorders.

10. To prevent Waste in racking, and, at the same Time, to dispose Cyder for becoming fine the sooner, Recourse must be had to Percolation.

Get Flannel enough for five or six Bags, each containing five or six Quarts. Let those Bags be made of a conical Figure, like a Sugar Loaf, or what the Gentlemen of the Faculty do affect to call by their Master's Name, the Sleeve of HIPPOCRATES: (as if the Prince and Father of Physicians had carried some of his Art in his very Cloathing, and so his Disciples pinned their Faith upon his Sleeve in a literal Sense.) Let the small Ends of these Bags hang downwards, that the Cyder, by its impending Weight, may the sooner be impressed through them. Let the upper and open Parts be edged or bound round with Inkle; that they may the better support the Weight of the Liquor.

11. When your Bags are thus prepared, get a strong Hoop, and having fastened two Sticks across in it, tie up your Bags to them. The Center, where the two Sticks meet, having a Rope fixed to it, and the Bags being made to hang perpendicular over a large Vessel, pour that Cyder into them, which remains at the Bottom of each Hogshead after racking; and which is too foul to be mixed with the Rest. By this Method Abundance of Cyder (and fit for common Use) may be preserved, which must otherwise have been thrown away with the Lees.

12. An empty Hogshead must be kept on purpose for the Reception of the percolated Cyder, into which it must be thrown from Time to Time, as soon as it is strained. The Cask must be closely bunged, as often as the Cyder is thrown into it, lest the Liquor become flat by being too much exposed in an open Vessel. The percolated Cyder must also be racked, when there is a good Quantity of it together, and it is become tolerably fine.

13. To adapt your Cyder to all Palates, you may, either at your last Racking, or just before you bung and stop it up, * mix several Sorts together, and so render your Cyder rough or mellow, to what Degree you think fit.

* *There are that a compounded Fluid drain*
From diff'rent Mixtures, and the blended Streams
(Each mutually correcting each) create
A pleasurable Medley, of what Taste
Hardly distinguishable. PHILIPS.

14. By thus mixing your Cyder, you may give all that you intend for your own Table, the agreeable Taste of the White-Sour. The Juice of this Pom-Royal being of such a predominant Quality, as to communicate its Flavour, in a very distinguishing Manner, to all the Cyder with which it is in any due Degree mixed, Providence seems to have ordained it for this very Purpose.

I know, indeed, that in the Parts about MODBURY and KINGSBRIDGE, in DEVON, where the White-Sour Fruit doth much abound, the People are more tormented with the Gout, than in any other Part of the County. This they attribute to the Use of White-Sour Cyder. But ought they not rather to impute their gouty Complaints to their Grout Ale of several Sorts, with which those Parts no more abound than any other! Are not these Liquors too foul to have a clear Passage through them; and what becomes of their foul Contents? Must they not of course rack and torment the Bodies that harbour them?

But, if these Gentlemen are so in Love with their grouty Liquors, as not to perceive the Mischiefs they suffer from them; (for, of all fermented Drinks, those of the Grout Kind seem to be the worst) if they are resolved to acquit the guilty, let them not be so unfair, as to condemn the innocent. Before they appear in open Rebellion against this King of Cyder Fruit, and take up Arms to lop off the Heads of their White-Sour Trees, and to graff them to another Kind, (which, I am told, they are confederated to do after many Years Mutiny) it is no bad Advice to them to suspend their intended Hosti-

An Elevation of a Farm House, with the Orchard Planted in Quincunx, and the Ground Cultivated between it.

lities, and to try the Difference, by racking their White-Sour Cyder more, and by drinking leſs of it unmix'd than they are wont to do. If theſe tender-footed Gentlemen do really find their White-Sour Cyder potent and ſearching, even after they have well ſubdued it by racking; one Hogſhead of it (like what the Merchants call their Full Wine) will ſerve to improve two of another Sort, and to render all three more fit for their own Tables at Home, if not for the Markets Abroad. For White-Sour Cyder communicates its Virtue and Flavour to other Juices, as a merry Companion doth Life and Spirit to every Member of the Society in which he is engaged. And who would fall out with a Liquor ſo friendly and diffuſive of its Favours, as to diſtribute them thus frankly, and without Reſerve, for the common Good?

15. Various are the Practices of People in ſtopping up their Cyder; ſome doing it early, and others leaving it open till CHRISTMAS, and longer, if the Weather continues mild, or the Froſt be not ſevere.

As I have fully experienced both Ways; ſo I muſt give my Judgment in Favour of the latter. Due Regard ought, however, to be had to the Nature of the Fruit, and to the Time of pounding: for as the Cyder which is firſt made, may, at CHRISTMAS, be twice as old as the laſt pounding; ſo, coming from a more early Fruit, and therefore ſooner diſcharging its windy Effluvia, (the only Uſe and End of its being left open at all) it ought, for that very Reaſon, to be the ſooner bunged up.

16. While your Cyder continueth unſtopped, a ſlight and looſe Covering of Board, which may reach from Hoop to Hoop, ought to be put over the Bung-Hole, to prevent the Duſt, Rats, and other Annoyances, from breaking the thin Film, or unctuous Subſtance, which inveſteth the Surface of the Cyder; as a Guard intended by Nature for its Preſervation, like Oil upon a Flaſk of FLORENCE Wine.

17. Eſpecial Care muſt be taken alſo to fill the Hogſhead to the very Top of the Bung-Hole, at the laſt racking; that if any light or flying Lees remain in the Liquor, they may be removed at the Bung: for this is frequently the Caſe of mellow Cyder: and if thoſe Lees are permitted to remain in it, the Surface of them, by being expoſed to the Air will become ſour. That Tartneſs will by Degrees render all the Cyder (whether it be in a Hogſhead, or in a larger Veſſel) of the ſame Complexion. Yea, the Taint may be perceived to deſcend gradually: for while the Cyder is ſour at the Top, it is ſound a few inches below it; till (like the Palſy, which takes its Riſe from the Capitol, or Brain, the Seat of the nervous Stock) it deſcends from Head to Foot, from Top to Bottom.

18. This is the grand Article in which People are wont to be deceived, and by which they are rendered out of Love with racking of Cyder, how much ſoever they are pleaſed with it, when it happens to anſwer their Wiſhes: for when their Cyder turns ſour, they are ſo weak as to imagine that racking takes away the Spirit of it, and that it muſt then become ſour of Courſe, for Want of a Body to ſupport it, as they are wont to ſpeak: whereas, in truth, it grows ſour for Want of Skill how to ſecure it after the laſt racking; by removing the light Lees which ſwim on the Top of the Liquor, before they acquire any the leaſt Degree of Acidity from the impending Air, to which the Cyder is expoſed. And if the Hogſhead is not full, or the Bung-Hole is not large enough to admit the doing of this by a Spoon, the Cyder muſt be racked again, though it be as clear as Rock-Water, or as fine as Amber: And Racking indeed is the ſureſt Way; for ſome of the Lees may eſcape the Spoon, and therefore there is no certain Dependance upon it.

19. And under the Article of Racking I muſt moreover obſerve, that the Perſon employed in racking your Cyder, muſt be particularly careful to waſh and dry his ſtraining Bags, racking Tubs and Buckets, leſt they caſt a ſour Look upon him at the Time of his next Racking. He muſt be as neat in his Cellar, as a Maid in her Dairy. No more Marks of a Sloven muſt appear in the Veſſels of the one, than of a Slut in the Utenſils of the other. For Want of this Precaution, as the Dairy abounds with a worſe than CORNISH Sour-Milk; ſo the Cellar is ſtock'd with a deſpicable Sort of Vinegar.

20. The Seaſon for * bottling of Cyder for the ſecond Year's Uſe, (as that of the White-Sour, Mediate, Redſtreak, Fox-Whelp, and others of the ſtrongeſt Kinds) is at the End of AUGUST, or in the Beginning of SEPTEMBER; that the remaining Heat of the Seaſon may give it juſt Briſkneſs enough to preſerve it the following Winter.

* *Cyder in Bottles frail improves and ſmoaks*
Tranſparent, ſparkling in each Drop:
Delight of curious Palates, by fair Virgins crav'd;
Fallacious Drink! ye fair Maids beware,
Nor truſt its Smoothneſs: the third circling Glaſs
Suffices Virtue. But may perfidious Jilts
(That ſlily ſpeak one Thing, another think,
Hateful as Hell) pleas'd with the Reliſh weak,
Drink on unwarn'd; till by inchanting Cups
Infatuate, they their wily Thoughts diſcloſe,
And through Intemp'rance grow awhile ſincere.

PHILIPS.

Cyder thus ordered will be a prudent Reſerve againſt a Year of *Dearth, and ſtand good for ſeveral Years: longer, perhaps, than the Owner's Curioſity can prevail over his Appetite to keep it.

* —— *Elſe if the following Years*
Exhibit no Supplies, alas! thou muſt
With taſteleſs Water waſh thy drought by Throat.

PHILIPS.

21. But Regard muſt be alſo had herein to the Difference of Climates. My warm Situation (for Inſtance) in the Southern Part of the County of CORNWALL, near FALMOUTH, doth oblige me to defer bottling of Cyder till the End of OCTOBER, or the Beginning of NOVEMBER; and even then to let the Bottles remain uncork'd for ſeveral Days: otherwiſe (although I do not bottle my Cyder till it be two Years old) my mellow Cyder would burſt moſt of the Bottles; and thus (like a Chymiſt who hath laboured ſeveral Years in Search of the Philoſopher's

Stone, and put all his Materials into a weak Crucible, as the laſt and finiſhing Proceſs of his Skill) I ſhould be undone by the cracking of my brittle Ware, and ruined by my own Art.

22. My coſtly Experience this Way hath taught me alſo not to fill the Bottles higher than the Bottom of the Neck, even with rough Cyder, and lower ſtill with the mellow Sort. Hereby Room is left for the ſubtil and volatile Particles to play, and expand themſelves in the empty Space, without breaking the Bottles.

As for the Experiment of a certain judicious Naturaliſt of the preſent Age, in putting a ſmall Piece of round Cork into each Bottle, for Prevention of Miſchief, I never tried it. For if the Cork happens to be muſty, or the Parts of it to be ſeparated in the Bottle, it will either prove an Injury to the Liquor, or be an Eye-Sore in it. But it calls to my Mind a beautiful Compariſon of a late celebrated Writer; namely, that a great and able Stateſman out of Buſineſs, is like a huge Whale, which will overſet or daſh in Pieces a large Ship, if he hath not a light, empty Caſk to play with.

23. That your Stock of bottled Cyder may be kept from Leakage, the Corks muſt be tied down with ſtrong Packthread.

The Bottles ought alſo to be laid upon their Sides, that the Air may not find its Way by the Cork, ſo as to hurt the Liquor. The ſame Caution is needful in all other Liquors, except diſtilled Spirits, and a few Sorts of the moſt potent White-Wines. But when the Bottles are placed on their Sides, Care muſt be taken to decant the Liquor with the ſame depending Side downward on which the Bottles lay in the Cellar, that ſo the Sediment may be left behind.

24. And thus I have finiſhed that Part of my Eſſay which relates to the ordering of the Fruit; to the making, managing and improving of the Cyder to the beſt Advantage; and to the Rules proper to be obſerved in bottling of it, and in decanting of it, ſo that it may be preſented to your Friends at the Table in the moſt elegant Manner.

To lay down Rules to People, how and when to drink their Cyder for Health, as well as Pleaſure, may be deemed a needleſs Undertaking; becauſe they will tell me, that every one is the beſt Judge of his own Conſtitution.

But as the Deſign of this Eſſay is to rectify the Manners of my Countrymen, as well as to cure their Cyder; ſo I muſt here obſerve, that although Cyder, when well cured, be both a healthful and pleaſant Liquor, and is therefore well adapted to an ENGLISH Conſtitution; yet it is not to be drank at all Times, and by every Perſon that can ſwallow.

There are two Sorts of People to whom I ought in this Place to addreſs myſelf; I mean thoſe who will not drink Cyder, and thoſe who cannot forbear turning Sots upon it.

I am very ſenſible, that many of thoſe of the better Rank, who have been accuſtomed to the Juice of the Grape, have their Judgments ſo perverted, and their Palates ſo vitiated, that they cannot condeſcend to the Uſe of this common plebeian Liquor, becauſe it is ENGLISH.

And it may well be pleaded indeed in Excuſe of their Prejudice, that good Cyder being the Production of but few Counties in the Kingdom, even thoſe which do moſt abound with it, have it ſo often * adulterated with Preparations of Treacle, boiled Sugar, Brimſtone, Iſing-glaſs, Cochineal, boiled Cyder, and a Number of other Ingredients which I could mention; that, inſtead of being an innocent Liquor, (as it is in itſelf) it becomes a very offenſive one. For while ſuch over-buſy Practitioners do only ſtudy how to pleaſe the Eye, and to cheat the Palate, the Stomach (which ought to be chiefly regarded) is entirely neglected. Whereas, by attending to the plain Dictates of Nature, and narrowly watching her Operations, they might keep their pernicious Train of Ingredients and deſtructive Artillery for other Purpoſes; and render their Cyder more agreeable to the Sight, more delicious to the Taſte, and much more wholeſome to the Stomach without them.

* *This I warn thee, and ſhall always warn:*
No Heterogeneous Mixture uſe; as ſome
With wat'ry Turnips have debas'd their Wines,
Too frugal. Nor let the crude Humours dance
In heated Braſs, ſteaming with fire intenſe,
Altho' CORNUBIA *much commends the Uſe*
Of ſtrength'ning VULCAN. *With their native Strength*
Thy Wines ſufficient other Aids refuſe:
And when th' allotted Time is run compleat,
Are more commended than the labour'd Juice.

PHILIPS.

On the Score of the many Tricks practiſed upon Cyder, it was that I drew up theſe Memoirs ſome Years ago, at the Inſtance of that worthy Member of the Royal Society, of whom I have given ſome Intimation in the Preface. That Gentleman had ſtudied Nature very narrowly; and as he reckoned Cyder the moſt healthy Liquor of any, and was determined to confine himſelf to the Uſe of it, and to have it managed under his own Eye, that he might preſerve it genuine; ſo he might well confide in my Sincerity, at leaſt, as to the Rules of doing it. Of theſe I gave him a Specimen in a perſonal Conference at his own Houſe; and was really as anxious for the Preſervation of his Health, as he had before ſhewn himſelf truly judicious in preſcribing Means for the * reſtoring of mine.

* ——————— *What Returns*
Of Thanks were due to his Beneficence
Freely vouchſaf'd, when to the Gates of Death
I tended prone? If his indulgent Care
Had not prevented, with unbody'd Shades
I now had wander'd, and theſe empty Thoughts
Of Cyder periſh'd. But, up-rais'd by him,
Each Day and Night my Duty I repay'd
In grateful Taſk his Liquor to amend,
And render pure; as he had done my Blood.
The honour'd Name of M—— *ſhall ſtill employ*
My Thoughts, and dwell for ever on my Tongue.

I might, from this Paſſage, take Occaſion to enlarge upon the Virtues of Cyder, as a good Diuretick, Pectoral, and even a Cooler of the Blood too, as well as a Diluter of it, when taken in a moderate Way. But this is the Phyſician's Province, not mine. I only undertake the Cure of the

the Fermentation of Cyder, not that of the Blood and Humours.

But as Cyder is allowed by the Gentlemen of the Faculty, to be a good Antiſcorbutick alſo; and hath been known to continue ſound through an EAST-INDIA Voyage: yea, to become better by twice croſſing the Seas to and from that remote Part of the World; and to * imitate the Taſte of ſeveral Sorts of Wine: ſo I have often wondered that the Board of Admiralty have not, till of late, directed the Uſe of it to his Majeſty's † Navy; and that Maritime Perſons in the Merchants Service too, when bound upon long Voyages, ſhould ſet out from their reſpective Ports without a competent Stock of it.

* *Some Cyders have, by Art or Age, unlearn'd*
Their genuine Reliſh, and of ſundry Wines
Aſſum'd the Flavour. One Sort counterfeits
The Spaniſh Product: this to Gauls hath ſeem'd
The ſparkling Nectar of Champaigne: with that
A German oft hath ſwell'd his Throat, and ſworn,
(Deluded) that imperial Rhine beſtow'd
The generous Rummer. Whilſt the Owner pleas'd
Laughs inly at his Gueſts thus entertain'd
With Foreign Vintage from his Cyder Caſk.

PHILIPS.

† *Where'er the Britons navigate their Ships,*
Diffuſive to the utmoſt Bounds of this
Wide Univerſe, the Britiſh Cyder borne,
Will pleaſe all Taſtes, and triumph o'er the Vine.

PHILIPS.

Much might be advanc'd in Commendation of Cyder, and in Point of Health, to gain it the Preference to Foreign Wines, how neatly ſoever they are ſaid to be imported; yea, though they are found to anſwer too that Character of the inſpired Writer; namely, to make glad the Heart of Man. For all Wines abounding with tartarous Salts; and the Fermentation of them being quieted, while their Spirit is raiſed by a Mixture of Brandy in their Cure, the frequent Bibbers * of them do contract the Seeds of the Gout, Gravel, Scurvy, and other Maladies, to which this our BRITISH Wine doth not render us obnoxious.

* *I need not tell what dreadful Ills attend*
Immoderate Uſe of Wine: nor all the Kinds
Of Maladies that lead to Death's grim Cave,
Wrought by Intemperance: Joint-racking Gout,
Inteſtine Stone, and pining Atrophy. PHILIPS.

I muſt not here omit the Names of two eminent Phyſicians, *viz.* Sir JOHN FLOYER, and Dr. BAYNARD: the former of whom found much Benefit in a ſevere Aſthma; and the latter owed his Life twice, when in a moſt deplorable and confirmed Phthiſis, or Conſumption, to the Uſe of Apples and Pomaceous Juices.

And if this Fruit was not the Growth of ENGLAND, but the Production of the INDIES, it would, probably, upon the Strength of ſuch Authority, have been celebrated more than it is in our Diſpenſatories, by QUINCY, ALLEN, JAMES, and the Writers in that Way: be brought over to us either dried or in Conſerve: have a top Place in Phyſical Preſcriptions: and be cloſeted by the Apothecaries among their other rare and coſtly Drugs.

For that Apples are great Preſervatives, as well as good Reſtoratives of Health, let the ſeveral Inſtances quoted by the ſaid Dr. BAYNARD ſuffice to ſhew. Among other Things in Commendation of Apples, he tells us, in his Hiſtory of cold Bathing, p. 314. of a Gentlewoman and her three Sons, who came to HOLLAND, from ſomewhere near POMERANIA, to claim an Eſtate which fell to them as next Heirs, by the Death of ſome Relation: and that the Sons, as well as the Mother, were ſo very old, that, betwixt them all they made up four Hundred and thirty-ſeven Years. For what the younger were ſhort of a Hundred, the elder were above a Hundred; which compleated the ſame Number of Years. Whether they lived a Century, or more, beyond that Term, our Author doth not ſay. But when their Way of Living, as to Eatables and Drinkables, was enquired into, it appeared that their Drink was chiefly Apple-Water, or Crab-Apples bruiſed and ſteeped in Water; and their Meat plain, ſimple, Country-Fare, with but little Fleſh.

Now as their Drink was what we in ENGLAND call Beverage, that is, a Mixture of Water and Cyder: ſo the Place of their Habitation being on the Borders of POMERANIA (a † Country famed in Hiſtory for Plenty of Fruit, and abounding perhaps with Apples too, from which it ſeems to derive its Name) theſe, probably, were a great Part of that plain, ſimple, Country Food by which our Author tells us they prolonged their Lives. Their Fleſh Diet was very moderate; juſt enough (we may ſuppoſe) to cook up that ENGLISH Diſh of a Squab Pie upon Occaſion, and when, in entertaining their Friends, they indulged a little beyond the common and ordinary Way.

† *See Collier's Dictionary.*

But I ſay no more upon this tender Point, leſt I give Offence to the Profeſſors in the Medicinal Art, and ſo draw upon me the Cenſure of an arrant Quack, by aſcribing ſuch wonderful Virtues to ſuch contemptible Means.

I knew myſelf ſecure from the Diſpleaſure of my celebrated Æſculapius. For as he was no leſs famed for his diſintereſted Spirit, and Publick Humanity, than for his great Skill in Phyſick: ſo, in his various Reſearches into the Secrets of Nature, he would have been glad to have found all the Virtues of the Materia Medica contained in a ſingle Apple; that he might have had the Pleaſure of obliging the World with the valuable Secret.

And yet it is very evident, that if an effectual Remedy was found ſo near at Hand for the Cure of that ſingle lingering Diſeaſe of the Conſumption only, a great Part of the Phyſicians Buſineſs would ceaſe. Yea, the Inventor of this Sovereign Elixir Salutis, though he might be rewarded by his Prince with a Patent, muſt yet expect to be pelted by the Fraternity in general, for exploding the large Trumpery of Phyſick; as St. PAUL was by the Crafts-Men, for baniſhing the Heathen Gods out of the World; and ſo bringing the Gain of their Craft or Occupation to nothing.

And now I am come to Scripture Teſtimony, it may ſuggeſt, perhaps, a Fancy to the Reader, that that Divine ought to be accounted Heterodox,

and of a different Opinion from the Church; a Sceptick, or a Free-Thinker, who dares aſcribe any Sanative Virtue to a Fruit, the prohibited Uſe whereof ſome fondly conceive to have been the Introduction of Sickneſs, Diſeaſes, and even of Death itſelf, into the World.

But ſurely the Apple ought to have the ſame fair Plea, and Indulgence, with a reputed Criminal at the Bar: I mean, not to be condemned by Hear-ſay, or Conjecture, till the Guilt is roundly and fully proved. In the mean while let the frequent, and approved Uſe of Apples after * Dinner, (even at Tables moſt abounding with other Proviſions, and as proper to help Digeſtion after a full Meal) ſerve to vouch for their Innocence at leaſt, without retaining a Counſellor to plead it in Court vivâ voce.

* —— *ab Ovo*
Uſque ad Mala. HOR.

I muſt obſerve further, that the Hurt did not ſeem to lie in the Paradiſiacal Fruit itſelf, but in the Tranſgreſſion of the Divine Command. The Prohibition might have been annexed by God to whatever Subject he thought fit. But on what Fruit ſoever it was fixed, the Fall of Man is not to be aſcribed to any pernicious Quality in the Fruit itſelf; but to the Diſobedience of a curious, unruly Appetite; edged on by Pride, and by the ſly Inſinuations of that cunning Serpent the Devil.

Not but that it hath been conjectured by ſome very learned Men, that the Fruit of the Forbidden Tree was impregnated with ſome fermenting Juice, which (like that violent Operation too frequently perceivable in Cyder) put the Blood and Spirits of our firſt Parents into great Diſorder; and thereby diveſted them of the Power and Dominion which their Souls had before over their Bodies. That it clouded their Intellects, corrupted their Wills, and reduced every Faculty of their Minds to a ſhameful Deformity, to a miſerable Depravity. Like that INDIAN Juice, which is ſaid to turn even the moſt ſagacious and ſenſible Man that drinks it into an Idiot, or natural Fool.

Suppoſing therefore that the Miſchief did lie in the Fruit itſelf, I ſhould be inclined, from thoſe ill Properties of it, to conclude, that the Grape, and not my favourite Apple, was the very Fruit forbidden. For it was the Juice of the Grape which gave the firſt Occaſion to Drunkenneſs, that we read of. By which the firſt Divine Orator, or Preacher of Righteouſneſs, was befooled and cheated out of his Reaſon, and became expoſed to his own Family: a Shame and Scandal to his Children: a Spectacle not to be endured without a Covering to hide his Deformity. A NOAH transform'd, for a while, into the Condition of a Brute; and wallowing in the Mire and Filth of Senſuality.

With the bewitching Juice of the ſame Sort of Fruit, but rendered ſtill more miſchievous by the Art of the Diſtiller, unknown to the Ante-Diluvians, (which reduceth groſs and large Bodies into a ſmall Compaſs; as all the Evils, Diſeaſes, and Calamities of Life were ſaid to be crowded together in the little Box of PANDORA: which is a conciſe Repreſentation of the woful Effects of the Fall of Man, according to the Heathen Theology) by their Brandy I ſay, our Neighbours of FRANCE, with their Serpentine Cunning, do draw us into the Snare. For this Liquor (which is extracted from their worſt Wines, and even from Dregs) if not warily uſed, becomes of the ſame intoxicating Nature with the LETHEAN Waters. It obliterates, for a while, all the Traces of Reaſon. It deſtroys Men's Memories, makes them forgetful of what is paſt, and renders them unfit for preſent Service. It blunts the Edge of their Underſtanding, and enfeebles their Bodily, as well as Rational Powers.

Hence a late Phyſician of much Note in the Literary World, as he was in the Practice of his Profeſſion, hath wittily called all Sorts of Liquors, in which Brandy makes a Part of the Compoſition, "The Devil muzzled."

But notwithſtanding the Muzzle, the Cyſtis, or Bag of Poiſon, lieth concealed under the Tongue; and all the Liquors with which Brandy is wont to be mixed, cannot waſh away its Venemous Quality. The moſt that can be ſaid in Favour of ſuch compounded Liquors is, that thoſe who drink Brandy in Mixture with other Ingredients of an innocent or leſs offenſive Nature, may be ſaid to do it with ſome Caution, though with ſome Imprudence. But thoſe who drink it unmixed (Puris Naturalibus, according to the Tippler's Language) they really do it without either Fear or Wit; their Conduct is as bad as their Latin.

In the laſt War with France, when our Priſons were not large enough to contain the Priſoners, thoſe of the FRENCH who had the Liberty to walk Abroad upon their Parole, did ſometimes, in cold, froſty Weather, call for a Dram of ENGLISH diſtilled Liquor at our Publick-Houſes. But when inſtead thereof, a Dram of FRENCH Brandy was brought to them, I am credibly informed, that they only ſmelt the Liquor, but refuſed to taſte it; ſaying, it was good for ENGLISHMEN but not for the FRENCH. So hoſpitable are they to furniſh us, in a very plentiful Manner, with what they do not think it ſafe to drink, or even to taſte, themſelves! And why ſhould not the ENGLISH be equally cautious of this combuſtible Liquor, who are not ſo well acquainted as the FRENCH are, with the Way and Manner of its Preparation?

To return from this long, but not altogether uſeleſs, and impertinent Digreſſion.

The Management of Cyder is a Secret, which the Curious are too fond of keeping to themſelves. As People have their different, and peculiar Ways of doing it, according to their ſeveral Fancies; and as they are notoriouſly ambitious of excelling one another, in this Domeſtick Liquor: ſo, one would think, there was a Spice of Envy mixed with their Emulation, which hinders them from communicating their ſeveral Arts. They converſe freely enough upon various Kinds of Huſbandry; and upon the ſeveral Ways of ordering and managing their Lands, in ſuch a Manner as to reap the moſt advantageous Returns from them. But, amidſt their other Friendly Diſcourſes and Communications, they are ever reſerved and wary upon the Sub-

Subject of Cyder. Here they ſit as mute as the Gentlemen of the long Robe; who, when a Caſe of Property is ſtated to them in Company, and Queſtions are aſked about it, do rarely open their Mouths without a Fee; till a chearful Glaſs hath relaxed their Tongues from their wonted and profeſſed Taciturnity; and opened their Hearts to a generous Diſcloſure of their Thoughts.

Yea, even thoſe who have obliged the World with Rules and Methods for Improvement of Lands, by the Plantation of Orchards, and from thence have paſſed on to Cyder; even theſe, I ſay, have handled this uſeful Subject but ſlightly, and in Tranſitu, as it ſtood in their Way to ſome other Article in View.

Some of them, it muſt be confeſs'd, have been nice enough in deſcribing the ſeveral Engines for making of Cyder: but when it is made, they even leave it to the Mercy of Chance, whether it prove drinkable or not.

Others have, moreover, recommended a Separation of the good Cyder from the Lees: which, in the modern Dialect, we term Racking. But then they are ſo looſe in their Reaſons for, and Rules of doing it; that the Reader is ſtill left to gueſs when, and how, it ought to be done. Hence is is that that Bee of Arts and Sciences, Mr. CHAMBERS, in his Univerſal Dictionary, hath ſaid ſo little upon this Article. Although (like the painful Creature above) he hath ranſacked Woods and Foreſts, Hills and Mountains, Sea and Land, and the Univerſe itſelf, for Honey to ſtock his Hive with: yet (for want of other Flowers, I ſuppoſe, to make a Collection from) he is obliged to take up with a ſingle Quotation from Mr. WORLIDGE; and the Reader is ſtill to ſeek for that Information which he expected.

Nor indeed can the Cyderiſt be, any other Way, perfect and compleat in his Art, than by narrowly attending to the whole Courſe of Fermentation. He muſt as nicely watch the ſeveral Periods of it, as a careful Phyſician notes the ſeveral Periods of an intermitting Fever, in a Patient whoſe Life he is anxious to preſerve.

If any clear and diſtinct Treatiſes of Cyder have hitherto been publiſhed, they have eſcaped my Hands; and ſo fall not under the general Character above. For want of the Sight of any ſuch, I conceived there might be Room in a wide World, for this little Manual. I have been the more exact and particular in laying down the Rules, and in aſſigning the Reaſons of them, for the Supply of the imaginary Defect above. Inſomuch that I think I have rendered every thing clear, plain, and intelligible to the very meaneſt Capacity. For I have penn'd it for the Service of the Farmer *, as well as of the Gentleman *; for the Uſe of the poor Rack-Holder, as well as for his rich and wealthy Lord. I have therefore endeavoured to put the Rules in ſuch a Dreſs, and to expreſs them in ſuch Language, as to adapt them to the Taſte and Comprehenſion of every Reader.

* ——— *Lo thoughtful of your Gain,*
Not of my own, I all the live-long Day
Conſumed in Meditation deep, recluſe
From Human Converſe: nor, at ſhut of Eve
Enjoy'd Repoſe: but oft at Midnight Lamp
Ply'd my Brain. Racking Studies, if by Chance
You I might counſel right. And oft this Care
Diſturb'd me ſlumb'ring. Will you then repine
To labour for yourſelves? And rather chuſe
To lie ſupinely, hoping Heav'n will bleſs
Your Cyder thus neglected; or give Bread
Unearn'd by Toil?

PHILIPS. No. 52.

But as Rules of all Kinds are jejune and dry; and a Sort of dead Letters, if there be not ſomewhat to quicken them: ſo I have intermixed Similitudes with them, and added a few Digreſſions to them, to divert the Reader, and to make them go down the better. Juſt as Apothecaries are wont to pleaſe and humour their Patients with gilded Pills. The Aſa-Fœtida thus concealed, is taken by the niceſt Ladies without Reluctance; though the Leaf-Gold is confeſſedly of no Manner of Uſe in Phyſick.

Some imperfect Draughts of this Eſſay have crept Abroad, and been well received, I hear, in many diſtant Parts of this Kingdom. For Strangers are always welcome, when they give the Maſters of the Houſe no Trouble; nor put them to any Expence in their Entertainment. But they are more eſpecially ſo, when, beſides the News they carry with them from their own Country, they offer to ſerve their Entertainers gratis; and without Meat, Drink, or Wages, to become Caterers for their Profit, as well as Pleaſure.

If any of thoſe few, whom I have obliged with the Rules for Improvement of their Cyder, do look upon Obligations of the ſame Kind to others, as an Infringement upon their Property, by thus breaking down the Encloſure, and turning the little Spot, as it were, into a Common: my Anſwer is, that I am very much miſtaken, if I have ever yielded up the Poſſeſſion into envious, mercenary, or ſelfiſh Hands. My Deſign in imparting it to a few, was, that it might be communicated to many, and ſo ſerve, in ſome Meaſure, the Ends of the Preſs; to which I had no Thoughts of committing it, had it not been ſuggeſted by a particular Friend, as a uſeful Article to be inſerted in the Book of Huſbandry. And I ſhould be glad to hear, from my Readers in general, as I have already from thoſe who have had the Manuſcript Copies imparted to them, that they have as good Cyder of their own Growth, by a cloſe Obſervance of theſe Rules, nay much better than they can meet with at the publick Markets from the SOUTH-HAMS, or HEREFORD.

I am well aware that this Tract will appear in the Book of Huſbandry, like a Stranger in a Publick Theater. Some may caſt a favourable Eye upon it; but others will look aſquint. There is one Claſs of Men in particular who will ſcarce forgive me, and from them I expect no Thanks. Theſe are the Cyder Merchants: or ſuch as make it their Trade to buy Cyder from the Pound, to manage and to ſell it at LONDON, and other populous Places.

But when theſe Dealers conſider, that although this Eſſay may prove of ſome Diſ-ſervice to their parti-

particular Employments, or Way of Business: (as it will teach every Farmer how to cure his own Cyder at Home, without being put to the needless Expence of sending it to the publick Cellars for that Purpose) yet if it will turn to the Publick Benefit, by improving a considerable Branch of the National Revenue; they will, surely, shake Hands with me. At the worst they cannot be so severe upon me, as not to pardon an Attempt which so directly aims at the Publick Good. Yea, perhaps, they may herein espy something (how unwilling soever they may be to acknowledge it) which had before escaped their Observation: or for which they could not render a proper and substantial Reason.

But whether they will acknowledge this or not, it is certainly the Interest of every Nation, to carry their Home Manufactures to the highest Perfection they are capable of; that so they may live as independent of their Neighbours as possible; and also export the superfluous Products of their own Country to Foreign Markets.

But alas! while instead of improving our Cyder, so as to render it fit for our own Tables, and saleable Abroad, our Heads are only projecting how to get Foreign Liquors to mix with it, and so to spoil, instead of improving it, in that costly Way; we are burthened and overstocked with both, by a clandestine and destructive Trade with France, we part with our Money, and (which is still more valuable on the Score of the many Hands employed in the Woollen Manufacture) sometimes with our Wool too: and so keep our Enemies warm against External Colds, for several Years; while in Exchange, they only warm us within for a few Minutes. We please ourselves with the Name of Sampson (that is to say, Brandy and Cyder) but, like silly Prodigals, we wantonly part with the Golden Locks, in which our Strength doth lie.

I know it is a difficult Thing to stem the Tide of general Practice, and to persuade Men to any thing against their Inclination. It is like pressing upon them those hard Lessons in Religion of plucking out a right Eye, and cutting off a right Hand. It is a tearing up by the Root the darling Affections of their Heart.

To put an old Brandy Drinker, for Instance, under the Mortification of a total Abstinence, is like putting a Knife to his Throat, for he cannot live without it. He hath so over-heated his Constitution with this combustible Liquor, that Cyder, alas! is become too cold for him. He fancies that he should be dead soon, if he hath not something to warm and comfort his Heart; especially in cold and frosty Weather; upon a Journey; after hard Labour; and to keep him warm while he is so; at least to prevent his cooling too fast, and to keep his Blood from being chill'd. Yea, Brandy is become an Antidote for all Intemperance, both in eating and drinking; just as one Sort of Poison is prescribed by the Physician for expelling another. Thus a Dram is exhibited by the Master of the Feast after a plentiful Dinner, or the Use of gross Food. It is the only Latin that we hear at Table for Pig and Goose in particular. It pinneth up the Basket, as we say, and becomes the last Glass at parting, after a Deluge of other Liquors. Yea, Tea, and Punch itself, are fancied not to sit quite easy upon the Stomach, without a clean Dram for a Rider. Thus Brandy hath the good Luck to obtain the Fame of a Sovereign Cordial: of a Catholicon that hits every Disorder: that is suited to all Constitutions, to all Times, to all Places, and to all Occasions.

I have found many People in the World thus befooled to their Ruin, and have had an Account too of many more. But I am still sensible that the Corruption is not universal. I shall therefore think my Pains well bestowed, if they afford sufficient Caution to the uncorrupted Part of the present Generation, from falling into this fatal Snare, from whence their Friends or their Fore-Fathers did confess it even impossible for them to recover.

But I must not leave such poor miserable Creatures as I find them. If they are not already so blinded and besotted by this intoxicating Liquor, as to be entirely lost to their Reason, I must beg them to consider that, instead of supporting their Spirits by Brandy, every Dram is a Sort of fresh Wound, or Stab inflicted upon themselves; and that therefore every such repeated Act of Suicide, or Self-Murder, doth require also a particular Act of Repentance to wash away the Guilt thereof.

Nor must I look upon them as incurable, and so forsake them; as the Physician uncourteously turns his Back to his Patient, when he finds the cold Sweat upon him. For though the Disease of Brandy-drinking may be reckoned of the most inflammatory Kind, and highly malignant: yet while there is Life there is Hope; and a Cure may be wrought without running the Risque of a dangerous Experiment, or a desperate Remedy.

As those who have enervated and blunted their Reason, by this stupifying Liquor, are rather to be taken by Guile and Artifice, than to be wrought upon by rational Inducements: so I would recommend to them the pretty Device of a Dutch Doctor, upon the like Occasion.

Finding his Patient too far gone in the Phrensy of drinking Brandy, to be cured of the ill Effects of it by Physick: that his Appetite to Food failed him; that his Pulse was quick and intermitting; that he had a Cough upon him; and that he had all the Symptoms of Night Sweats approaching, and so of his entering upon the last Stage of a Consumption; the Doctor thought it expedient to remove the Cause of the Disease, instead of dosing him with Physick; and so weaned him gradually from that fatal Practice by this artful Stratagem. He did not debar him from his favourite Cordial at once, but indulged him the Use of it upon this easy Condition: namely, that he should strictly observe to put a large Duck Shot into his usual Dram Glass, every Time before he took his Dose. For Lead, said the Doctor to him, is of a cooling, healing, balsamick Nature; and therefore good to refresh and strengthen his weak and tender Lungs. By the frequent Addition of Shot, and their Continuance in the Glass with some of the Liquor, under Pretence of Infusion, for an Hour, (according to the Doctor's Direction) the Dose was reduced at last to the Quantity of a

Tea-

Tea-ſpoonful; and by that Means he both reclaimed and recovered his Patient. For he grew well in Proportion to the gradual Diminution of his Doſe. A very honeſt and cheap Preſcription for the Cure of this wretched Malady of Dram-drinking. Not as other Sorts of Madneſs are cured, by Evacuations of all Kinds; by the tedious and painful Experiments of Cupping, Bleeding, Bliſtering, Vomiting, and Purging; and ſometimes by the Correction of Chains too: but by the imperceptible, and daily Abatement of the wonted Superfluities of the Glaſs; and by a ſlight Curb, and eaſy Reſtraint upon an inſatiable Appetite of Liquor. And thus the Vices of the Mind, as well as the Diſeaſes of the Body, are beſt cured by Practices oppoſite to thoſe that begot them.

The Uſefulneſs of this Subject of Cyder muſt apologize for my having ſtepped out of my Profeſſion to treat of. And if an IRISH Prelate hath condeſcended, for the Good of his Country, to enter into a Minute and Philoſophical Examination of the Virtues of Tar-Water; and to extract a Panacea from the inſpiſſated Juice of an Exotick Tree: why ſhould a poor ENGLISH Vicar be deprived of the Pleaſure, or be debarred the Liberty of caſting his Mite into the Publick Treaſury, by improving a Liquor of our own Growth, and of which we have ſuch a vaſt Conſumption among us?

The Rules laid down in the Beginning of this Eſſay I have fully experienced, in a Courſe of many Years Reſidence in the SOUTH-HAMS. When others have found as good Succeſs in the Obſervance of them as I have met with, by rendering their Cyder from Fifteen Shillings a Hogſhead, (the prime Coſt at the Pound) worth Five Guineas; yea, as valuable as an Hogſhead of Wine (each of which I have actually refuſed for a Hogſhead of CORNISH Cyder) they will, at leaſt think themſelves ſo much obliged to me, as to ſay; that neither their Labour, nor my own, hath been ill-beſtowed. I have received the thankful Acknowledgments of many, who have frankly declared, that their Cyder, which before uſed to be thin, poor, and hungry, hath, by their following theſe Directions, proved ſo rich, full, and good, that their Friends (eſpeciall thoſe who have been bred in the Maritime Way) have, during the Summer Seaſon, called for it at Table, and preferred it to the beſt of Port-Wine: and, in plain Terms, they reckon it a valuable Article in Houſe-keeping.

But I muſt be ſo ſincere with my Reader, as to acquaint him, that thoſe who have followed my Rules but in Part, and who have been diverted by a Multiplicity of Buſineſs, Company, Recreation, or Pleaſure, from giving a due Attendance to their Cyder, they have found themſelves much deceived in their Expectations, when it was too late to amend their Fault. Like heedleſs Practitioners in Phyſick, who diſmiſs their Patients with a ſingle Phlebotomy, and Box of Pills, and take no farther Care about them, till their whole Maſs of Blood is corrupted, and their Conſtitutions are quite emaciated. But although, in chuſing an Aſs for their next Doctor, the Patients may happen to be reſtored, by the Balſamick Milk of that, otherwiſe contemptible, Creature, to a tolerable Share of Health: yet the Cyder is gone (as we ſay) paſt Recovery, and beyond the Art of Man to cure.

But as this Diſſertation is intended for the Benefit of my Country in general, and more eſpecially for the Uſe and Service of thoſe Parts of the Kingdom which do moſt abound with Cyder: ſo it would ſorely grieve me to hear that an ill Uſe is made of it. It would much trouble me, I ſay, if ſome leading Member of Parliament, who is not a Repreſentative for a Borough in DEVON, HEREFORD, or CORNWAL, ſhould, in the Vacancy of State-Affairs, have the Curioſity as well as Leiſure, to caſt his ſagacious Eye upon it; and ſo, in Envy to the ſingular Happineſs of the few Counties famed for Cyder, ſhould be tempted to move for an additional Duty upon it, in ſome future Seſſion. For, if repeated Struggles have been made in the Houſe of Commons, about taxing the Juice of the Apple as a Potable only: to what Height may the Debates riſe, when a ſecond Sir R—RT ſhall appear there; and, with all the Flow, Grace, Dignity, and Force of Senatorial Eloquence, ſhall move and ſuggeſt, that Apples do not only ſupply us with Meat and Drink, but that they ſerve us alſo for Phyſick as well as Food.

For that the Apple affords a healthful Nouriſhment, is evident not only from the Foreign Examples of the POMERANIANS, cited above out of Dr. BAYNARD; but alſo from Inſtances near at Hand, of the Inhabitants of the SOUTH-HAMS (where the Seeds of this imperfect Eſſay did at firſt appear) and of the County of HEREFORD (which was the Scene of Mr. PHILIPS's Poem on the ſame Subject.) For as Apples, cooked up in various Forms, are a conſiderable Part of their Food from the End of JULY to the Beginning of DECEMBER: ſo Cyder is their principal and conſtant Liquor throughout the Year. And yet a more healthy Body of Men, or more * chearful in their Way, and truly merry in their Compotations, cannot be found throughout the Kingdom.

* *The Farmer's Friends, at thirſty Hour of Duſk*
Come uninvited: he, with bounteous Hand,
Imparts his ſmoaking Vintage, ſweet Reward
Of his own Induſtry. The Nut-brown Jugg
Circles inceſſant, whilſt the humble Cell
With quiv'ring Laughs, and rural Jeſts reſounds.
Eaſe, and Content, and undiſſembled Love
Shine in each Face: the Thoughts of Labour paſt
Encreaſe their Joy. ———
Gladſome they quaff, yet not exceed the Bounds
Of healthful Temperance, nor ſteal from Night,
Seaſon of Reſt: but well bedew'd repair
Each to his Houſe with unſupplanted Feet.
E're Heaven's emblazon'd by the Roſie Morn,
Domeſtick Cares awake them. Briſk they riſe
Refreſh'd, and lively with the Joys that flow
From amicable Talk, and moderate Cups
Thus ſweetly interchang'd. No noiſy Brawls
Ariſe from ſocial Glaſs. May BRITONS *all,*
Remote from brazen Sound of War, enjoy
Nectareous Cyder, and with ſeemly Draughts,
Enkindle Mirth, and hoſpitable Love.

——— *But let them thank*
That Providence which annually supplies
Their Cellars, and with her rare liquid Gifts
Exhilerates their languid Minds, within
The Golden Mean confined: beyond there's nought
Of Health or Pleasure found. But when thy Heart
Dilates with fervent Joys, and eager Soul
Prompts to pursue the sparkling Glass, be sure
'Tis Time to shun it. If thou wilt prolong
Dire Compotation, forthwith Reason yields
Her Empire to Confusion, and Mis-Rule,
And vain Debates. Then twenty Tongues at once
Conspire in senseless Jargon: nought is heard
But Din, and various Clamour, and mad Rant:
Distrust and Jealousy to these succeed,
And Anger kindling Taunt; the certain Bane
Of well-knit Friendship. Now horrid Frays
Commence: the Bumper-Glasses now are hurl'd
With dire Intent: Bottles with Bottles clash
In rude Encounter: round their Temples fly
The sharp-edg'd Fragments: down their batter'd
Cheeks
Mix'd Gore and Cyder flow. Ye Heav'nly Powers
From BRITISH *Isles such dire Events remove*
Far distant; neither let our civil Broils
Ferment from social Cups! May we enjoy
Our humid Products, and with temp'rate Draught
Enkindle Mirth and hospitable Love!

PHILIPS.

But it must also be noted, that when they happen to take a cheerful Cup, they commonly know their Quantum Sufficit, wind up their Bottoms, and either return to their Labour, or to their Rest. Thus they enjoy an almost uninterrupted Health: feed (as we say) like Farmers; and avoid those Excesses by which the intemperate Part of Mankind are led into many Inconveniences; to the Ruin of themselves, of their Fortunes, and of their Families.

If any should here observe, that I have overshot my Mark, and that Cyder, Sobriety, and Temperance are very distant Subjects; I have this to plead: that in directing People how to make their Cyder better I should have done them more Hurt than Good, unless a seasonable Caution had been interposed and interwoven, if I may speak in the Phrase of a Woollen Manufacturer, with the several Threads of this Essay, to make the Drinkers of this Liquor to become better also. To render their Cyder more palatable, would be only laying a more subtil Snare to entrap them, unless I had also pressed and recommended a temperate Use of it.

The ENGLISH are, by their very Enemies, acknowledged to be a brave and a warlike People. Even the King of FRANCE (if Credit may be given to the Publick Papers) allows them to have Hearts, though he is pleased to deny them Heads. And it must be confess'd indeed, that ENGLISH Heads are mightily injured, but not totally destroyed, by FRENCH Brandy. His Majesty therefore may be said to deal by us as the PHILISTINES did by SAMPSON; first to blind us by his intoxicating Spirits, and then to jest upon, and make Sport with us. But when we recover from this Lethargick Fit, as SAMPSON's Hair grew again, and his Strength with it, the Pillars of absolute Monarchy may possibly shake, as those of the Temple of DAGON were removed by the Hands of the Giant; avenging himself at once upon the PHILISTINES, for their unseasonable Mirth, and for the Loss of his two Eyes.

I do not speak this to exasperate our Military Men; but to imprint in their Minds this seasonable and certain Truth: that if they were as sober as they are naturally brave, they would excel in every Station of Life. They would shine both in a Council of War, and in the Field of Action. Their Enemies would no more come near them in the Stratagems, than they are able to withstand them in the Exploits of War.

That excellent Rule, he that striveth for Mastery is Temperate in all Things, is as needful to be observed in the Carnal, as in the Spiritual Warfare. A sober Warrior keeps his Reason cool, awake, and considerate. He hath the free Use of all the Powers and Faculties both of Mind and Body. His Head is as quick to distinguish and contrive, as his Eye to espy, and his Hand to execute. He soon discerns the most weak, open, and unguarded Parts of his Enemy's Troops, or the least Defects in their Fortifications: and as boldly pusheth his Way thro' their Ranks, forceth their Lines, or mounteth a Breach. By the Rules of Temperance (the Sister of Fortitude and Prudence) thus steering his Course, as the Sun doth by the Zodiack, like that glorious Luminary he is bright in all his Faculties, indefatigable in the Charge assigned him, and rejoiceth as a Giant to run his Course. In this active, yet unwearied Manner, methought I beheld with grateful Eyes, in the last War, our BRITISH Hero traversing Sea and Land; and no sooner leaving FLANDERS, than appearing in the memorable Field of * CULLODEN, and charging the insulting Rebels with such undaunted Bravery (in Defiance of their once formidable Back-Swords) as to put them to a perpetual Flight, we hope, as well as Shame.

* ——— *Here might you see*
Lairds, and their Clans on the embattled Field
Slain, or half dead, in one huge ghastly Heap
Promiscuously amast: with dismal Groans,
Ejaculations in the Pangs of Death!
Some call for Aid neglected: some o'erturn'd
In the fierce Shock, lie gasping and expire,
Trampled by fiery Coursers. Horror thus,
And wild Uproar, and Desolation reign'd
Unrespited. The young Adventurer
With long-stretch'd hasty Strides forsakes his Host,
Trembling, agast, not venturing to look back,
Posting for FRANCE: *but leaves the envy'd Crown*
behind,
His Title and Descent best prov'd by Flight;
Witness thou BOYNE: *and witness* CULLODEN ———
May GEORGE'S *Crown long flourish on his Head*
In spite of FRANCE *and* ROME! *May* CUMBERLAND
Continue long to guard his Father's Throne!

On the contrary, if we take a View of Sottishness, we shall find it the Parent of those twin Sisters, Folly and Cowardice. The Person addicted to it cannot have his Senses nor his Intellectuals clear. His Head is filled with gross Fumes, and his Understanding clouded. A Mist continually obscures and veils his Reason. Tho

Virtues

Virtues of his Soul are lulled asleep; and he is hush'd and becalm'd into Ruin. His Bodily, as well as Rational Faculties, are brought into Bondage, and laid in Chains of Iron. He becomes weak and enervated in both: and the Soldier in this Condition, like his Drum without Braces, is unfit for the Battle.

Should I here pass over the BRITISH Sailors, they would rage and storm upon me, as not thinking them worth my Notice: though I really esteem them as a very valuable and a very useful Body of Men: and the more I know them the greater Reason I find to respect them. Among Friends Freedom of Speech is allowable, and the honest Tars cannot blame me for wishing, that they were to be reclaimed by Reflexions of this Nature. But alas! they are such a merry, thoughtless, jovial Crew, that they are only to be cured by Time and by dear-bought Experience. They are such an active, and yet such an idle Sort of Men; so averse to Fatigue and Labour, and yet so fond of running into the most busy Scenes of Life: so profuse of Money, and yet so often hazarding their Lives for it: so fam'd, in short, for the Extremes of Activity and Indolence, of the eager Thirst after, and the visible Contempt of, Gain, that they seem a perfect Riddle, and to surpass all Description.

But amidst such various Contrasts as center in their single Character, the Courage of ENGLISH Sailors doth either attone for all their Failings, in the Eye of their Fellow-Subjects, or casteth a favourable Covering over them. Their Valour is not to be parallelled among the Maritime Tribe; and no more admits of Contradiction, than it will submit to Opposition. I can compare them to nothing better than to ENGLISH Cocks, which, though they exceed all others upon the Pit, can yet contentedly riot upon a Dung-Hill.

But, to their Honour be it spoken, considering the many Hardships and Difficulties which they had to contend with in the last War, they sometimes even out-did themselves, and performed Wonders. Though, like the finny Tribe, they derive their Livelihood from the floating, turbulent, unsteady Element, and their Bread is cast upon the Waters: yet they have been often obliged to pull it out of the Fire too. As if they could not enough distinguish their Bravery without courting Danger, they have often engaged betwixt a double or treble Fire of the Enemies Cannon; that so, like that very Gold which they at once covet and despise, they might by such a Purification, appear with the greater Lustre. Yea, when they have been over-powered by a much superior Force, they have disdained to strike to FRENCH Colours, but in the last Extremity; and when their wooden Castles became so leaky, that the Deep was ready to swallow them up. But, amidst all their brave Engagements, and their many signal Feats at Sea, it is reasonable still to suppose that they would have performed more, had the common Sailors been as sober and temperate as many of the Commanders and inferior Officers, under whom they fought.

But among all the valiant Exploits at Sea, I should be wanting, in Respect to my quondam Parishioner Captain PHILIPS, did I omit to mention his gallant Resolution in cutting an ENGLISH Man of War out of a FRENCH Harbour. An Action not unlike that of JASON, so much celebrated in antient History: the bringing back the SOLEBAY, together with two Hundred and fifteen FRENCH Prisoners in it, from the Road of St. MARTIN'S, being, to all Human Appearance, as impracticable as the fetching the Golden Fleece from COLCHOS.

As this Action stands singular in the ENGLISH Annals, so the BRITISH Argonaut's Misfortune was singular likewise. For his not being bred in the Navy excluded him, by the Rules thereof, from the just Reward of his Merit. His Majesty, however, was graciously pleased to distinguish him, and to bind him, as it were, by the strongest and most significant Tie of his Royal Bounty: namely, by a Gold Medal affixed to, and pendent on, a treble Gold Chain. But the Command of his own Prize was what he had at Heart; as it would have afforded him more Room for the Display of that Bravery, which, for want of a stouter Ship, he afterwards signalized upon the INDIAN Coast, in a diminutive Packet-Boat.

Having thus paid my Acknowledgments to the ENGLISH Soldiers and Sailors, it would be but a low Compliment passed upon them to say, FRENCH Brandy is not good enough for them. Could I render ENGLISH Cyder like the famed Nectar and Ambrosia of the Heathen Gods; or the more modern, but no less fictitious Liquors of Aurum Potabile, to make them immortal, and so to cause their Lives to be as durable as their Fame, I should not think it above their Desert. But, as they would still covet a Sip of the right Nants, or Coniack: so, if a Cordial Whet is to be indulged to any who are not under an actual Deliquium; those surely have the best Title to it who fight our Battles: and who, upon a Push, may require just as much as will suffice to blunt the sharp Sense of Danger, to quicken their Spirits, and to push them on to Action.

But let them ever remember, that true Fortitude cannot be instilled from the Alembick. It flows from a much nobler Fountain; namely, from the steady and immutable Principles of Religion: which arms its true Professors with Courage in all Extremities. It will not permit them tamely to yield unto, or sneakingly to draw back in, the most threatening Dangers: where the Rights and Interest of their King and Country do demand their Assistance. For "Christian "Heroes (to use the Words of a late * Military "Person upon the same Subject) will expire in "Heaps before his Pavilion, to guard the im- "portant Life of their Sovereign; and, in the "joint Cause of Heaven and Earth; of our "Religion and Liberties, destroy like ministring "Angels, or die an Army of Martyrs."

* *Mr. Steele's Christian Hero.*

When the Reader considers that we are just upon the Brink of a bloody War, he will pardon a Digression, which is meant to whet the Courage, and to fix the Resolutions of those, who are like to be concerned in the most busy Scenes of it. And howsoever the ENGLISH may be represented by a neighbouring Power (like POLY-

PHEMUS in LUCIAN) ſtrong, but blind: yet we truſt that (through the Goodneſs of that Providence which hath ever befriended us) we ſhall be ſupplied with the Eyes of ARGUS, to watch and direct the State, as well as with the Hands of BRIAREUS to fight our Battles.

A Change of Topicks in Writing, as well as of Buſineſs in Huſbandry, ſerves for Amuſement. If theſe Political Remarks do not afford the Reader that Sort of Entertainment, which the Title Page gave him Reaſon to expect throughout the whole Eſſay; I muſt frankly confeſs that the Subject is of ſuch a barren Nature, and lies ſo much out of the common Way of Writing, that, like the Apple itſelf, it will not afford any Juice without ſqueezing. I have therefore been ſometimes at a Loſs even for Words to cloath and convey my Sentiments in, ſo as to render them intelligible. For Cyder, though a liquid Subſtance, is yet a very dry Subject to write upon. Hence it came to paſs, that in his celebrated Poem upon it, Mr. Philips, though a Writer of a very lively Fancy, found himſelf obliged to make many Excurſions into Similitudes, Perſonal Characters, and other Amplifications, quite foreign to his Favourite Nectarian Juice. Some of his Obſervations I have referred to; and they are ſet down without mentioning the particular Page. Since the Review of the firſt Manuſcript Copies, many freſh Hints have ſtarted up, which are inſerted here. They could not, without ſome Reluctance, be either prevented or ſuppreſſed: the Conceptions of the Mind being like thoſe of the Body; and, when once formed into a Fœtus, the Burden encreaſes daily.

Several worthy Gentlemen have deſired to ſee theſe Cyder Directions printed for the common Good; and have offered a handſome Encouragement for their Publication by Subſcription. But when I made a Motion to one or two of them, for their Patronage of them, they modeſtly refuſed to have their Names prefixed to an Art, which they did not pretend to have the Skill to protect, becauſe they did not underſtand the Art itſelf.

The Veſſel is therefore launched, without a Pilot, into a wide Ocean of Contradictions: into a World of Yeas and Nays: of Commendation and Blame: of good Report and evil Report: of Praiſe and Calumny. As it is thus committed to the Rage of Wind and Storm, it only remains that I wiſh it a proſperous Voyage, for the Benefit of Poſterity; and ſo I bid it Adieu.

End of the ELEVENTH BOOK.

A COMPLEAT BODY OF HUSBANDRY.

BOOK XII.

Of the Accidents to which the Cattle and the Crops are liable.

CHAP.

1. *Of Heat considered in itself, and its Effects on the Stock and Crop.*
2. *Of Drought, its Nature and Effects.*
3. *Of the Care of Fields in the Management of Shelter.*
4. *Of suiting the Crop to the Soil to prevent the Effects of Drought.*
5. *Of the Effect of Drought on Trees, and the Way to defend them from it.*
6. *Of preserving Water for Cattle in Seasons of Drought.*
7. *Of obtaining Supplies of Water when the common Ponds are dry.*
8. *Of the Signs and Notices of Drought to be observed by the Farmer.*
9. *Of Rains.*
10. *Of the Signs and Notices of Rain to be observed by the Farmer.*
11. *Of the several Signs of fair Weather.*
12. *Of Hail.*
13. *Of Snow.*
14. *Of Winds.*

CHAP.

15. *Of the Signs by which Winds may be foreknown.*
16. *Of the Damages done by Winds to Husbandmen in their Crops.*
17. *Of the Nature of Blights.*
18. *Of the antient and modern Opinions concerning Blights.*
19. *Of the real Cause and Origin of Blights.*
20. *Of Damages by easterly Winds.*
21. *Of Damages by late Frosts.*
22. *Of Damages from Weakness and Starving.*
23. *Of the Nature of Mildew.*
24. *Of the real Cause of Mildew.*
25. *Of the Prevention of Mildew.*
26. *Of the Remedies of Mildew.*
27. *Of Smuttiness of Corn.*
28. *Of the real Cause of Smut.*
29. *Of the Prevention of Smuttiness by a due Care of the Land.*
30. *Of the Prevention of Smut by a prudent Method in sowing.*
31. *Of preparing the Seed against a smutty Crop.*
32. *Of the cleaning of smutty Corn.*

The INTRODUCTION.

AS it has been our Custom in the preceding Parts of this Work, not only to inform the Husbandman of such Things as it is necessary for him to know; but to explain them as minutely and exactly as we are able, that by being familiar to his Understanding, they might be imprinted in the more lasting Manner on his Memory: we shall endeavour to prosecute the same Method here, though in this Case more difficult than any other. There is the more Reason for attempting it, because such a Knowledge is in no other Article so necessary. The Accidents we are about to treat of are of the most important Kind; and if the Causes of them be not properly understood, they never can be prevented. For this Reason, we shall in the first Chapters of this Book examine into, and so far as that can be done, explain to the Husbandman the Nature of such Incidents in the Air and Elements which are the Occasions of many of them; that

that by underſtanding in what Manner the Hurt is done, he may know what are the Means in his Power, if there be any, to prevent or guard againſt it.

Under this Diviſion we ſhall alſo conſider the Meteors, as the Learned call them, Rain, Hail, Snow, and the Reſt; and inſtruct our Huſbandman how far he may be able to foreſee them, and conſequently be prepared to guard his Flock and his Crops againſt the Danger they naturally would receive from them.

After we have thus enquired into the Cauſes, we ſhall trace the Effects in thoſe Diſorders they occaſion in the ſeveral Parts of the Huſbandman's Concern; and thus endeavour, under this moſt important Head, to lay down in a few plain Words a Syſtem of *Rural Philoſophy*; which if not enough to ſatisfy the utmoſt Curioſity of idle Minds, ſhall yet offer every Aſſiſtance that has been diſcovered to ſerve the practical Farmer.

CHAP. I.

Of Heat conſidered in itſelf, and its Effects on the Stock and Crop.

THOUGH Heat be the very Principle of Life in the Univerſe, yet it may be attended with fatal Conſequences to every Thing in Nature. The Degree determines the Utility of every Thing; and in the preſent Caſe, that which when moderate is the Support and Preſervation of all Things, when exceſſive is their Deſtruction.

We are not here to enter into the Effects of Heat in the Condition of actual Fire, which diſſolves, diſſipates, or deſtroys all known Subſtances; but that Degree of it only, which may be in the Temperature of the Air. The Farmer will not bring Metals to the Furnace, nor expoſe Gold or Diamonds to the Power of great Burning-Glaſſes, which in their full Force ſcatter the one, and ſplit the other to Shivers: theſe are the Amuſements of Philoſophy; we are concerned only with its Uſe. We ſhall confine ourſelves to the Nature and Effects of that Degree of Heat which is at times felt in the Air, and to its Influence upon the Cattle and Produce of the Ground: and as we limit this Work to the Service of the Farmer, we ſhall advance nothing but what ſtands on certain Proof, and what his Reaſon will find it eaſy to comprehend.

Our Iſland is ſubject in the Summer Months to very conſiderable Heat, when Accidents conſpire to continue it unallayed. Nature has ſo well adapted the Creatures of the Iſland to this, that they are none of them deſtroyed by it; nor the ſmalleſt Plant, unleſs irregularly expoſed to it: but its Effects are very hurtful, though not ſo great as utterly to kill them. We ſee Cattle fainting and loſing their Fleſh, and Plants fading and drooping, according to the Degree of the Heat; and this the Farmer is with his Care to prevent, by Shade and Shelter for the one, and by watering the other when needful.

Many Plants, and moſt Animals, bear the Effect of Cold better than that of Heat, for this plain Reaſon, that the Cold only condenſes their Juices, whereas the Heat diſſipates them.

The Effects of this Temperature of the Air are more ſenſible on Plants than Animals; wherefore we ſhall principally conſider them in that Light.

Many Plants will grow in a very conſiderable Degree of Cold: but when it comes to freezing, tho' a Multitude endure it and keep alive, yet few have the Vigour to ſhoot. The ſlighteſt Froſt ſtops the Growth of moſt Plants, and a Degree ſomewhat ſtronger it ſtops that of all.

This is a Principle perfectly eſtabliſhed by Experience, and the Farmer will learn from it what he is to expect with Regard to his Winter Crop.

Young Plants ſuffer more by Froſt than thoſe ſomewhat advanced in Growth; therefore let him provide for ſuch as are to ſtand the Winter accordingly, and expect from them Nothing but what Nature will ſupport. Let him ſow them in ſuch Time in Autumn, that they may have ſome Strength before the Coming in of Froſts; and let him expect little more from them during Winter, than to eſtabliſh themſelves well in the Ground. In the Days of Froſt he ſees they can only ſupport themſelves alive, for to grow in that Time is againſt the Courſe of Nature; therefore what little Shoots they can make muſt only be during the open Weather; and theſe will be ſo checked by the Return of the Froſts, that there cannot be any great Progreſs.

As Nature has provided for the ſupporting the Generality of Plants alive during the coldeſt Weather we have in this Iſland, we are to be under no farther Concern on that Head; but to examine the various Degrees of Warmth and Heat; riſing from this, to the Extream of what our Seaſons afford.

The Warmth of the ſofter Winter Months brings Plants a little forward; the gentle Heat of the Spring makes them ſhoot apace; the greater Heat of Summer ripens their Flowers and Seeds; and even the greateſt as we have ſhewn is not enough to deſtroy them, unleſs the Negligence of the Huſbandman join with it.

A gentle Warmth puts the Sap of Plants in Motion; and the greateſt Power of it within Moderation, unites and cements their beſt Juices for the Formation of their moſt uſeful Products: but when we come to a Degree any thing conſiderably greater than this, it operates in a Way directly contrary to what we have named, ſeparating and diſperſing their beſt Particles, inſtead of bringing and uniting them together. It is therefore a Plant puſhes out its Flowers, and ripens its Fruit or Seed in this moderate Degree of Heat; but in the Extream fades and decays.

Many a Crop that might have produced very well is loſt, or comes to little, for Want of the Farmer's proper Aſſiſtance. Different Soils and different Situations make Plants bear Heat differently, ſome better, others worſe; as alſo their ſeveral Kinds. We have told the Huſbandman what Species ſuit what Soils and Expoſures beſt, having always kept this Article of Heat in Mind; and with proper Regulation there is ſcarce any ſuch Thing as a Crop's utterly failing this Account. When we conſider how much hotter ſome Countries are than ours, this will appear

pear leſs ſtrange; for there are Plants which live in the hotteſt of them.

Experiment ſhews what would ſcarce elſe be credible; reſpecting this Article, Dr. Hales, whoſe Veracity or Accuracy never have been or will be queſtioned, aſſerts, that Plants will endure without Prejudice a greater Degree of Heat, than that of Water made as hot as that a Perſon can but juſt endure to hold his Hand in it without ſtirring it about. He has therefore fixed upon a larger Degree of Heat than this for the utmoſt which Plants will bear, and aſcertains it at that Heat of Water upon which melted Bees-Wax begins to harden.

This is an Experiment very happily choſen, ſince Bees-Wax being a vegetable Juice, tho' collected by the Bee, ſuch a Degree of Heat as would abſolutely diſſolve that, muſt be the utmoſt Point Plants can bear.

This explains to the Farmer how much his own Neglect is to be blamed at many Times, when he gives up his Crop as ſpoiled by Heat: this is a Degree of it to which Plants never will be naturally expoſed with us: therefore he may for his Satisfaction eſtabliſh this Maxim; that if he conduct himſelf properly in all the Articles we have named, in the ſowing and Management of any Crop, it will never be loſt by Means of the Heat.

If a Weather-Glaſs of the common Make be divided into a hundred Parts from the Degree of Cold at freezing, to this Degree of Heat determined by the melted Wax, it will give all the Degrees of Heat to which Plants will ever have any Reference. Few Houſes are without a Weather-Glaſs, and the Farmers never ſhould. The Kind made for this Purpoſe is that called a Thermometer, and the Huſbandman will do well to have one with this Diviſion, which will come as cheap as any other. This will ſhew him at all Times what is the Degree of Heat in the Air, much better than what he feels at random by his Body; and according to this he will know in what Degree of Health, or in what Danger his Crop is from this Article.

In a Space thus divided, ſixty-four Degrees is about the Heat of the Blood in Animals. Experiments have ſhewn, that the Heat of the external Part of the Body is that of about fifty-four of theſe Degrees: the Heat of Milk as it comes from the Cow is fifty-five Degrees; which Degree is about the ſame that ſerves for the hatching of Eggs; and that of new made Urine is about fifty-eight.

Theſe Degrees of Heat being known, with Reſpect to the Parts and Bodies of Animals in Health, they give us a Mark by which to know their Sickneſs; and the Compariſon of what Degree of Heat our Summers commonly afford, with what Plants will bear, which is perfectly known by this Method, will farther confirm to the Farmer what we have aſſerted already, that when his Crops fail, as is ſuppoſed by Heat, it is not by the abſolute Effect of that, but by his Miſmanagement joined with it.

The common Degree of temperate Weather in this Diviſion is about eighteen Degrees; and the great Heats of Summer will raiſe it to eighty eight Degrees. This is a vaſt Advance; it is four and twenty Degrees hotter than the Blood of Animals naturally ſhould be: but even this, though without Care it will make Cattle faint, and expoſe them to Diſorders, yet is no leſs than twelve Degrees below the extreme Heat that Plants will bear without Prejudice, if they be properly managed.

There are Countries in which the Plants all endure this Degree of Heat many Months, for ſeveral Hours each Day, and more; but what is ſeen in them verifies what we have told the Huſbandman. They hang their Leaves and fade, and would be killed by it, but that they are ſupported and refreſhed by the great Dews of the Evenings and Nights in thoſe Places.

Nature has for this Reaſon made many of the Plants of thoſe hot Regions of ſuch a Form, that they have no Leaves; theſe being the Part that ſuffers moſt readily by the Violence of Heat.

Though we have named the Height of eighty-eight Degrees, as what the Weather ſometimes arrives at in our Summer, the Farmer is not to imagine that every Summer is ſo hot; much leſs that every Plant muſt of Neceſſity be expoſed to ſuch a Degree.

The common Heat of a Summer Day in the hotter Months, and in the Middle of the Day, is about fifty Degrees of this Meaſure. There is a great deal of Difference between this and the Heat marked at eighty-eight, which yet is twelve within what Plants may bear. But yet this is a Degree of Heat to which his Cattle are not expoſed, tho' a great many Parts of his Crop are. At thoſe Times when the Heat is at fifty Degrees in the Sun, which is to be called a Summer Noon-tide Heat, it is but thirty-eight Degrees in the Shade. The Farmer ſhould carefully obſerve this Article, that he may ſee what a vaſt deal is in his Choice by a proper Management. 'Tis true that the great Heats of Summer ſubject his Cattle to many Diſorders, as we ſhall preſently ſee at large; but he ſees here, that it is in his Power to moderate that Heat twelve Degrees in fifty by a proper Shade.

Motion encreaſes Heat to a very great Degree, therefore let him take care, that when the Days are hotteſt his Cattle are kept the moſt quiet. In the ſame Manner, as the Middle of the Day is the hotteſt Part of it, let them be kept particularly quiet during that Time. Theſe are Rules founded on plain Reaſon and daily Experience, yet though plain and obvious they are not ſufficiently regarded. The Huſbandman may, by an irregular Proceeding, heat his Cattle as much in May, as the Nature of the Seaſon would do in July: and on the other hand, by proper Hours of Reſt, and due Shelter, he may in the Effect reduce the moſt extreme ſultry Weather to the Condition of temperate.

With Reſpect of Plants, an Obſervation of the Degree of Heat, and of their general Condition and Progreſs, will ſhew abundantly the Truth of what was before aſſerted, reſpecting the Effect of a moderate Heat for promoting their Growth, and the Effect of a greater Degree of it in ripening their Seeds. At a Medium the Heat is in April at about fifteen Degrees. This with the Aſſiſtance of the Rains at that Seaſon ſets the Plants to ſhooting. In May

and the Beginning of June it advances from that to twenty, twenty-five and thirty Degrees; and in this Time they grow moſt, and ſtrengthen themſelves beſt. After this come the more extreme Heats, and the Seed ripens. In general the Degrees of Heat between twenty and thirty, are thoſe moſt ſuited to the Growth of Plants. If we may be allowed to give a Sort of general Calculation for the Reſt of the Year, we may ſay that the common Heat of the Beginning of Spring, and the Decline of Autumn, may be reckoned between ten Degrees and eighteen; and the Winter Heat within ten Degrees of the freezing Point.

CHAP. II.

Of Drought, its Nature and Effects.

WHEN the Summer Months beſide being extremely hot are alſo extremely dry, the Farmer's Crop never fails to ſuffer greatly, unleſs well aſſiſted by Art. In the hotteſt Countries there are the largeſt Dews; and in the ſame Manner, in our hotteſt Seaſons the greateſt Quantity of Moiſture is exhal'd from the Earth, and ſerves to refreſh the Herbs again in its Fall; but it is not enough to preſerve them in Vigour. Nature intended for them the Aſſiſtance of Rains, and when theſe are with-held, the Huſbandman muſt ſupply the Defect by his Induſtry.

The Products of open Field Land are moſt expoſed to the Damage that is ſuſtain'd from Drought, and Corn more than Paſturage; yet none are exempt. In Seaſons but ſlightly droughty the open Field Corn ſuffers, and the Farmer reaps but a poor Harveſt; and in the Extream of this unfavourable Weather there is little Graſs for the Cattle.

The Stock thus ſuffers by Means of the Scarcity of Food; and commonly there is great Want of Water for them at the ſame Time. Theſe, added to the natural Diſorder of their Bodies from the Heat itſelf, are Sources of many Diſorders; ſo that it is a very important Concern to the Farmer to make the beſt Proviſion againſt the Damage that he can, and to do all he can to remedy it when it happens.

The Method of preventing the Effects of Drought is pointed out by Nature: indeed the Huſbandman's whole Practice is ſo, if he would but follow her Steps. Let him ride about the Country in the Extreams of a droughty Seaſon, and obſerve the Effects of it on Lands that lie differently. We have obſerved that it is in open Fields the Effect is worſt; and in the others he will ſee the Damage leſs as the Encloſure is better. This may ſhew him that the proper Guard againſt the Accident of Drought, is by keeping up his Fences, and planting them well with Trees. We have ſpoke of this before, and recommended it very warmly upon the Conſideration of its Advantage in Reſpect of Wood: here is another and a very great one. The Effect of the warm Sun upon Plants of the ſame Kind in open Ground, is ten Times greater to do them Harm, than in ſuch a one as is well encloſed: we have ſhewn its Heat is greater, but that is not all; Droughty Seaſons are always attended with burning Winds: theſe parch up the Plants which the Heat only faded; and againſt theſe three joint Cauſes of Miſchief no common Plant can well ſtand. 1. The Heat diſſipates and evaporates a great Quantity of the Juices. 2. There is no Recruit from Showers for a Continuance of Time, and the Evaporation is all the while daily repeated; And, 3dly, The dry Winds follow, to ſhrivel up what the Sun had faded. Theſe are natural Conſequences; the Leaves wither and droop, no Moiſture comes to refreſh them, and Winds parch them up: they muſt fall off. We have, in a preceding Part of this Work, ſhewn what are the Nature and Uſes of Leaves on Plants; and it is plain the Loſs of them muſt be very deſtructive to the Whole.

We have laid down the Cauſe of the Miſchief Plants receive from Drought, to ſhew the Farmer the Propriety and Neceſſity of what we are propoſing by Way of Remedy. The Heat and Drought do their Damage but partially and ineffectually, unleſs the Winds come in to their Aſſiſtance. A Plant may droop and hang its Leaves from Day to Day for a conſiderable Time, and yet upon a ſmall Shower it will recover: but when a parching Wind blows over it upon the Heat, in that drooping Condition the Leaves fall, and then no Rain recovers it to any Purpoſe.

Now the Expoſure to theſe drying Winds appears to be the Thing that compleats the Deſtruction of the Plants; therefore the Farmer's Buſineſs is to guard againſt that. The Elements will not obey his Pleaſure, but he may defend his Crop from this Miſchief of Winds. The Sun will dart its Rays in Spite of all his Caution; and there is no Art by which he can make the Clouds drop their Treaſures of Water: to theſe therefore he muſt ſubmit; but the Miſchief of theſe is but partial and ineffectual without the Winds that follow: and tho' he cannot prevent theſe, he can guard his Crop againſt them. To this Purpoſe let him thicken his Hedges at the Bottom, and plant Trees in Abundance, that will grow to a Height, and almoſt meet by their Branches all the Way up. This will be a Defence not only againſt the Winds, but in ſome Meaſure againſt the Sun. The Thickneſs at the lower Part will perfectly well break the Force of the former, and the large Shade ſpread over the Field for a great Part of the Day by one or other of the Hedges, will defend the Growth againſt the latter. The Plants thus ſheltered will enjoy a State of the Air by many Degrees cooler, than if the Sun had its full Effect upon them: and there is another Advantage too little conſidered, which is, that the Number of Trees will, by the great Quantity of watery Matter they perſpire, render the Air leſs ſcorching.

The Profit of Wood will alſo recommend this Method of Shelter, for it is very conſiderable: on all Accounts we adviſe the Farmer to fall into the Practice, but ſtill within the Guidance of Moderation; tho' we adviſe him to thicken all his Hedges about thoſe Places, where from the Situation Drought is like to be moſt deſtructive; yet we mean this ſhould be done in a prudent Manner.

ner. The larger the Field the loftier ſhould be the Trees. For common ſmall Encloſures a well grown white Thorn Hedge, managed as we have directed, is a ſufficient Defence: in thoſe of a larger Extent the Pollard Hedge, of which we have given a Figure and Explanation from the Hand of an ingenious Correſpondent, will be the moſt proper; and for the largeſt, tall Elms, and other Trees of the like Kind, which are to be indulged in ſpreading out their Side Branches, provided they do not over-hang the Ground too much, or ſtarve the Head.

For this Purpoſe we ſhall adviſe the Farmer, in ſome Degree to imitate the Practice of the Gardener in his cutting of thoſe Trees, which he means ſhould grow fan Faſhion. Let him cut off the Boughs of theſe Elms and other Trees that grow toward one or the other Field, and encourage ſuch as run parallel with the Courſe of the Hedge. This will have a great Advantage: the Side Boughs will thicken, and will be a better Shelter and Defence, and the Growth will at the ſame Time ſuffer nothing from their Overſhadowing or Drippings. There muſt be always a fine leading Shoot left for the Top, to carry up each Tree in Height, while it is thus ſpreading Breadthwiſe; and with all the Advantage there will be a great deal of Beauty. This is a Thing not to be conſidered by the Huſbandman, at the Expence of Convenience, but when it falls in with that, 'tis certainly worth Regard. The judicious Eye abhors the Gardiner's Practice of clipping up Trees in this Manner in ſtrait Lines, Leaves and all, till they reſemble a Wall, becauſe it is ſtiff, formal, and out of Nature; but what we adviſe the Farmer to do, which is no more than cutting away ſuch large Boughs as ſtand ſtrait forward, will have a moſt pleaſing Effect. There will ariſe from it a Flatneſs and Breadth ſufficient to pleaſe the Eye, though not ſo formal as to offend it; and the remaining Branches will give the whole an Air of perfect Nature: ſuch Trees will look only as if they had chanc'd to have grown very prettily. Every Field will thus have the Aſpect of a Garden, only more natural and more beautiful.

CHAP. III.

Of the Care of the Fields in the Management of Shelter.

THE Huſbandman will ſee that we have thus contrived for him an eaſy, and a very effectual Remedy againſt the principal Danger riſing from Drought; but he will naturally obſerve, that theſe Hedges muſt be cut, and theſe Trees lopp'd at Times; and it will be natural to aſk, what is then to be the Defence of the Crop? The Anſwer is not difficult, nor is this any great Inconvenience. The Improvements introduced of late Years into Huſbandry, give the Farmer a great Advantage in the Variety of Crops; and he will find that Change in no Reſpect more ſerviceable than the preſent.

There are Plants which will endure Drought much better than others; and theſe he muſt contrive to have upon his Lands at the Time when he is to cut his Fences. This will not be difficult, becauſe the cutting theſe is always in his own Choice; he may not only do it when he pleaſes, but he may know a Year or two before hand, and provide accordingly.

The general Rule is, that the deeper Plants root the better they reſiſt Drought; and the Reaſon is very obvious, becauſe Drought affects Herbs only in Proportion to their want of Reſources againſt it, and theſe Reſources are always greater the deeper they are ſought. A little dry Weather will parch the Earth about a ſlight rooted Crop; but it muſt be a long Continuance indeed that can affect it to the Depth ſome of the new introduced Plants reach.

We have explained this Matter of the deep and ſhallow rooting of Plants in a preceding Part of this Work, therefore ſhall not repeat it here; but ſhall give the Huſbandman this general and univerſal Caution, that he proportion the Growth to the Condition of the Shelter. He will always know at what Time it will be bare, at what Time it will have grown to a moderate Defence, and when it will be in its full Perfection: therefore let him, againſt ſuch Years as the Shelter will be moſt perfect, ſow thoſe Crops that root the moſt ſlightly, and leave the Ground moſt open between them, for they will leaſt of all bear Drought. This laſt-named Article is more important than is imagined, for the Earth parches much ſooner where it is expoſed between the Plants, than where their Branches ſhelter it; and on this depends greatly the different Effect of Corn and Pulſe upon the Ground.

The Huſbandman's own Diſcretion will carry him on to ſow, for the Time of middle Growth of his Fences and Trees, ſuch Crops as require a moderate Shelter, but will not very eaſily be parched up: but the great Conſideration is with Reſpect to the Years in which the Fences will be bareſt. We have directed him to ſow ſuch a Crop as requires moſt Shelter, at that Time when the Hedges and Trees are thickeſt. We will ſuppoſe this the Year before the Trees are to be lopped, and the Hedges cut down: the next Seaſon therefore is to be that in which the Fields will be left moſt of all expoſed; and conſequently, if a droughty Year come, the moſt diſadvantageous.

Of all the Plants introduced into the Huſbandman's Profeſſion, Saintfoin is the deepeſt Rooter, and it beſt ſtands theſe Accidents; therefore let the Huſbandman provide a Crop of this againſt the cutting of his Trees. Let him ſow it early, and as it will then enjoy the Benefit of the thick Shelter while young, it will thrive ſo well as to eſtabliſh itſelf in the Ground before the lopping and cutting. It may then be left to Nature: it will ſtand the Expoſure made by this neceſſary cutting the Fences; and as it is a Crop that laſts ſeveral Years, it may very conveniently be continued upon the Ground while the Fences are growing up, and the Trees recovering their Branches. When they are grown ſo as to afford a good Shelter again, the Saintfoin may be broke up, and the Ground will be in excellent Condition for another Crop.

We have mentioned Saintfoin as an Inſtance, but the Farmer is not tied down to this only Plant,

Plant, he may take his Choice among all the deep Rooters, and they will bear this Management, ſerving him very well during the expoſed Years, and preparing his Land for Corn.

It is well known that dry and barren Lands ſuffer the moſt from Drought: therefore this Care ſhould be moſt of all taken with Reſpect to them: the Fences for them ſhould be planted thick, and the Trees at ſmall Diſtances in them; we have before given the Farmer his Choice of ſeveral that very happily ſuit ſuch Soils. In many Parts of the Kingdom, ſince Incloſures have become more general, Lands that were worth little while open, are come to great Value by this Article of Defence. The Crops on theſe Lands are leaſt able to bear parching Winds, and therefore they the moſt evidently of all ſhew the Effect and Benefit of Shelter; but this Effect on them is ſufficient to recommend the Practice univerſally, where there is Danger of theſe Accidents.

CHAP. IV.

Of ſuiting the Crop to the Soil, to prevent the Effects of Drought.

THERE are, as we have ſhewn, certain Soils which are more ſubject to have the Growth on them damaged by the Effect of Drought than others; and there are alſo certain Species which ſhew the Effect of thoſe parching Winds, that attend this Accident more than others, and that are leſs able to bear it: theſe Conſiderations ſingly may be of Service to the judicious Huſbandman, for providing againſt the Effects of this Temperature of the Elements; and when taken together, as we here propoſe to treat of them, they ſerve as a Kind of general Rule for his Practice.

We have adviſed him to look round about him, for the different Effects of the ſame Accidents on various Grounds: we ſhall now carry his Obſervation a little farther, and take in the State of Things in different Parts of the Kingdom.

We ſuppoſe the Farmer ſituated in ſome Spot where there are the common Accidents and common Advantages attending his Profeſſion; but from thence we ſhall now carry his Obſervation to thoſe Places where a great deal of the Land lies low, and in the Way of Damp and of Overflowing. The Soil in theſe Places, as we have before ſhewn, is uſually a rich deep Mould; and where they have the Advantage of any tolerable Plantations about them, they are from their low Situation well ſheltered.

In many Places Ditches are made to ſerve by Way of Fence. But this is an ill Practice on ſuch Lands, for they are by this Means expoſed to all the Damage of parching Winds. It is leſs than on dry barren Soils; but ſtill it is conſiderable.

Theſe Lands therefore we exclude from the preſent Obſervation: we ſpeak of thoſe which lie low, have a rich Mould for their Soil, and tolerable Shelter: of theſe there are Abundance about the Borders of the Fens; and if theſe be examined in the Years of Drought, they will be found then loaded with the largeſt and richeſt Crops.

Hence a Rule of Practice is very eaſily to be deduced. If the Farmer have ſuch Land divided by Ditches, and it bears poorly, while he ſees that of his Neighbours produce well; let him plant the Sides of his Ditches with Willows at moderate Diſtances, and as they have naturally a naked Trunk, let him ſet Oſiers between them. The Method of doing this we have delivered before, and the Effect in this Caſe will be very great. The tall Heads of the Willows will caſt a proportioned Shade, and the Oſiers, which are full of Leaves down to the Bottom, will keep off the Winds.

Only particular Crops will thrive where the Lands lie very low, which is uſually the Caſe where there are theſe Ditch Partitions; but all theſe Crops will receive vaſt Benefit in dry Years from this Fence.

We have adviſed the raiſing of Saintfoin on the Ground, that is to be left expoſed by the cutting of the Hedges, and lopping of the Trees; and we ſhall add, that on this Occaſion it is the Farmer's Buſineſs to ſow his Crops removed from thoſe higher and more expoſed Fields on this Occaſion, upon the loweſt Grounds he has; and thoſe which are beſt ſheltered.

The Saintfoin on the expoſed Ground will ſo cover the Surface with its Branches, that if a hot and droughty Summer follow, it will be much leſs affected by it; and the Herb receiving its Nouriſhment from a great Depth, will flouriſh, becauſe the Sun will not have Power to affect it at that Depth, when the ſuperficial Part is thus ſheltered; while the high Grounds thus ſtand out a Year of Drought in their moſt defenceleſs State, with a good Crop upon them; the lower Lands will, according to their Nature, yield the beſt Crops of all.

On the contrary, if an unexpected wet Seaſon happen, the Crop on the high Grounds will be the ſtronger and finer for it; and thoſe on the lower Grounds muſt be aſſiſted, as we ſhall ſhew when we come to that Head.

CHAP. V.

Of the Effect of Drought on Trees, and the Way to defend them from it.

TREES, like all other Products of the Earth, are liable to be affected greatly by Drought; but it is only while they are young: they are at that Time deſtroyed by it more eaſily than Plants of the herbaceous Kind; but when they are eſtabliſhed in the Ground, they remain unhurt by its utmoſt Violence. In this Experience confirms what is ſo plain from Reaſon, in the Effect of Drought, upon deep and ſhallow rooted Products. The principal Effect of this Accident is on the Surface of the Ground; and when the Root of any thing pierces to a proper Depth, the whole remains unhurt by all that happens above Ground.

We have recommended planting of Trees in waſte Grounds and in Hedges, and we ſhall here obviate

obviate the great Diſcouragement attending that Practice, which is the frequent failing of the Plantation from Drought.

We have, in treating of Planting, mentioned the ſeveral Accidents of Wind and the like, with the Way of guarding againſt them: theſe deſtroy many Trees, but Drought more than all: and this eſpecially where the Plantation is made on an expoſed barren Piece of Ground.

Theſe are the Places where Trees would be moſt deſirable, but from the frequent Failure of them Farmers have entertained a Notion they will not grow. That Nature can raiſe and ſupport them in ſuch Places is evident, becauſe we ſee them wild and of fine Stature, though it is ſo difficult to make them thrive when a Plantation is intended on ſuch Ground.

Let the Huſbandman imitate Nature. That is, let him ſow the Trees, of whatever Kind; and not plant them. And as we have told him what is the great Cauſe of their failing, let him guard properly againſt it.

The Practice of laying Stones or Rubbiſh about the Roots of new planted Trees, is very good, and may be alſo uſed for thoſe raiſed from the Fruit; but we have preſcribed a Method for the ſecuring of ſmaller Crops from Drought, which may, under a proper Management, be transferred to theſe with great Advantage.

The young Tree is the only Conſideration in this Caſe, for when eſtabliſhed it is ſafe; therefore let a Defence be raiſed for it while in that State. It is eaſy to ſow ſomething of this Kind at the ſame Time with the Tree, and they will riſe together.

It is true, every Shrub for Shelter will not thrive upon theſe barren Grounds where we propoſe Plantations, but there are enough that will. A poor Ground in an expoſed Field is the proper Soil for Furze; for we ſee it on the worſt Ground on the bleakeſt Heaths, and barreneſt Hills, flouriſhing well. This therefore will grow from Seed in theſe Places, and nothing can be more proper for the Service. Therefore when the Huſbandman ſets about a Plantation on this Kind of Ground, let him, at a Diſtance round every Spot where he intends a Tree ſhall ſtand, ſow a good Quantity of Furze Seed in a Circular Trench.

This will defend the young Shoot of the Tree from Winds, and alſo from Cattle. By this ſingle Contrivance the Shoot will riſe proſperouſly, and when it is out of Danger the Furze may be cut up for Uſe. Thus will a fair Plantation be raiſed by Nature's own Means; and it will ſucceed in the ſame Way as thoſe which are eſtabliſhed in like Places naturally. They have riſen from the ſcattered Seeds or Fruits of the ſame Kind, and have ſtood their Chance, and throve without thoſe Advantages, therefore doubtleſs theſe will do better.

If, after the Furze is removed, the Trees appear not to thrive well, from the Heat and Dryneſs of the Seaſon, and from the Expoſure, let the Farmer order a Bank of Earth a Foot and a half high, and a Yard broad, to be raiſed round the Bottom of every one of them, and they will immediately ſhew the good Effect of it in their reviving; this preſſes and ſtrengthens the Earth about their Roots; and it gives them, in ſome Degree, the Advantage of deep rooting, which we have obſerved to be the greateſt of all Defences againſt Drought.

CHAP. VI.

Of preſerving Water for Cattle in Seaſons of Drought.

WHILE the Crop ſuffers by the want of Rain, the Stock of the Farmer will be endangered by the drying up of the common Reſervoirs of Water: the utmoſt Care is therefore to be taken to preſerve what there naturally is; and to obtain more from other Sources when that no longer ſerves.

The common watering Places for Cattle, where there is not the Advantage of Brooks and Rivers, are certain Pits deeper or ſhallower, dug purpoſely, or on other Occaſions, which receive the Rain of the wet Months from the higher Ground, and preſerve it during Summer. Theſe are ſo eſſential a Part of the Farmer's Concern, that they muſt never be neglected.

Let him take Care to clean them at proper Times, that there may always be a due Cavity or Depth for receiving the full Quantity of Water. The Mud thrown out of them will pay the Labour, ſo it is doubly wrong to neglect it.

Let him examine whether they be well ſituated, and conſider whether they be of ſufficient Bigneſs. If they are not in the beſt Places let him have others dug where they ſhould be; and if they be well placed, but too ſmall, let them be ſufficiently enlarged.

The Obſervation of one Seaſon, eſpecially if it be a dry Year, will inform him how to judge in this Particular.

When the Pits are well placed, and of a due Size, let him obſerve how they hold the Water. If they become dry in the Time when they are moſt wanted, let him look into the Cauſe, and grudge no Price in, every Way, fitting them for the Purpoſe; for there is no Proportion between this Expence, and that which muſt lie upon him to ſupply his Cattle from other Reſources when they are dry.

Two Ways there are of a Pond's loſing its Water, and they are equally miſchievous, but equally within the Reach of Remedy. The Water may be loſt through the Bottom, or evaporated from the Surface, or both may conſpire to drain the Pond, and then there is no Hope of its remaining long in a Condition of Service.

Let the Farmer, when he digs a new Pit or Pond, provide againſt both theſe Accidents; and when he ſees an old one fail, let him examine whether one or the other, or whether both be in the Cauſe; and apply his Remedy accordingly. Let him obſerve how thoſe Ponds are conditioned that hold Water beſt, and imitate by Art what he ſees in Nature. When he caſts his Eyes about in a dry Summer, he ſhall ſee many of the largeſt Ponds altogether dry; and find in the Field many a ſmall Hole well ſupplied. Some old Sallow, or other ſuch Tree, grows at the Edge of it,

and under this the Water keeps quiet, cool, and freſh in the greateſt Heats. Let him examine the Bottom in theſe Places, and he will find it Clay; or if otherwiſe a Coat of ſtiff Mud covers the proper Soil, and anſwers the ſame Purpoſe. This ſhews that a ſound Bottom and a covered Surface are the two great Articles for the preſerving of Water. Therefore let him, in all new Ponds, clay the Bottom well, unleſs they be dug in natural Clay; and in all old ones, that loſe their Water by its ſinking, repair their Bottoms, or coat them altogether freſh. If a good Clay be uſed for this Purpoſe, and careful People employed to work it down, the Remedy is abſolute, for a Bottom of this Kind will hold as well as one of Lead.

When the Bottom is taken Care of, ſo that no Water can ſink; the next Attention is to be employed on Evaporation. The Sun dries up Ponds very much; and the Winds more. This is leſs obvious, but equally true. In their Salt Pits in France, where they evaporate Sea Water for making of Bay Salt, they find one Day's Sun, with a briſk Wind, takes off more of the Water, than three Days of the ſame bright Sun in a Calm.

The ſame Precaution that defends the Water from one of theſe, preſerves it from the other; this is the ſheltering it at the Edges. Let the Farmer keep in Mind the old Sallow, which he ſees over the Pond that retains the Water in its Hollow, while others are dry. This is Nature's Method, and this he ſhould imitate. Let him plant all about his new made or new bottomed Pond, except in one Place, which is to be left free for the Cattle to come down to the Water; or if it be in common to two Fields, which is a very good Practice, let him make two ſuch Openings. Let all the reſt be planted with any of the Trees that will thrive in a wet Soil; but of theſe none is better than the Kind already named, the Sallow, for it grows quick, and its Leaves do not give any ill Taſte to the Water. The Boughs of theſe Trees, as they grow, ſhould be made to ſtretch and meet from the two Sides, over the deepeſt Part of the Pond. The Sun will thus be kept off, and the Wind will have no Power. The Water will be kept in, and will be clearer than when it is diſturbed by every Blaſt. As none of it will be loſt: there are very few Summers in which Drought will be able to affect it.

If there be any where, in the adjoining Ground, a Spring, that ſhould always be brought in, and a good Conveyance made for the waſte Water; the Conſequence of this will be, that there will be a Conſtancy of freſh Water, and yet the Ground will be kept dry. The frequent Rains with us make our People neglect the Care of theſe Reſervoirs of Water too much; but in other Countries they are extreamly nice and curious about it, and if we took their Example, many of the diſagreeable Conſequences of Drought would be prevented. When the Farmer makes a new Pond, or new clays the Bottom of an old one, let him be careful to do the Work perfectly, for if there be the leaſt Defect where the Water can make its Way out, nothing will do but new working over the whole.

For a new Pond, one Coat of Clay, of eight Inches well ram'd, and another of ſix Inches, covered with rough Stones, is the beſt Method. For the new bottoming an old Pond, a ſingle Coat of Clay, and the covering of Stones, will anſwer the Purpoſe very well and very ſecurely.

CHAP. VII.

Of obtaining Supplies of Water when the common Ponds are dry.

AS the common Ponds will eaſily be exhauſted in a Seaſon of Drought; and the better made ones will ſometimes fail; it is needful to conſider farther what may be done in ſuch Extremity; for a Supply muſt be had ſomewhere, or all will be loſt. Thirſt to Cattle, as well as to Mankind, is more terrible when in the Extream, than Hunger, and is as certainly fatal in the End.

We have mentioned, in the preceding Chapter, the taking Advantage of Springs for the Supply, when they lie near the Surface: when they are not to be found there, they always may be had at greater Depths; and this is the proper Reſource, indeed the only one. Wells muſt be dug in fit Places, when all other Supplies of Water fail. It is often a diſcouraging Thought, to conſider to what Depths it may be needful to dig in this Caſe for Water, and what Expence may attend it; but, on the other hand, there is the abſoute Neceſſity of the Water, and the Certainty of the Supply: for Water may be had any where, if the Expence of digging be not ſpar'd. The Conſtruction of the Earth is ſuch, that there every where run Courſes of Wet at different Depths, uſually near the Surface, and rarely at a great Diſtance under it; wherever they lie they muſt be found on theſe extream Occaſions, or all will be loſt.

When the Well is deep, and the Supply of Water that is required from it is great, there muſt be proper Contrivances uſed for the getting it up. Men may be employed to draw it from ſmall Depths, and in moderate Quantity; where more Labour is required an Aſs may be uſed, or where there is Need, Aſſiſtances may be employed drawn from the Principles of Mechanicks.

The Wheel in which a Beaſt walks to raiſe Water from a deep Well, is a very good Contrivance: a double Wheel, with Coggs, is another excellent Method, becauſe it makes the Draught eaſier than in the common Way. The double Wheel, with a long Line to the Hand, is alſo another Improvement, becauſe the Weight riſes much eaſier.

Where there is a large Stock to be watered, the common ſmall Buckets are not to be uſed, for that would be endleſs; and in Proportion as larger are required, and the Weight to be drawn up is encreaſed, the more needful it is to be careful of the Force and Aſſiſtances in drawing. A very good Way of drawing great Quantities up with Expedition, is to place a large Wheel at the End of the Windlas, four Times at leaſt the Diameter of the Windlas. A thick Rope is to

be faſtened to the Bucket; and a ſmaller of due Length is to be wound round this great Wheel. The Length is to be ſuch, that when the Bucket is in the Water, the ſmall Rope is all wound upon the great Wheel, and the Bucket being filled, a Servant is to take the End of this ſmall Rope and go forward, till, as that unwinds, the Bucket is drawn to the Top.

Thoſe who are not acquainted with the Powers of Mechanicks, can entertain no Notion of the Effect this has. A ſingle Man will thus be able to draw up a Bucket of twenty or five and twenty Gallons, and that with great Expedition, and little Labour. This is a Thing of vaſt Conſequence, when large Draughts are required.

A good Contrivance, in Caſe of theſe large Buckets, is to have them made ſo that they ſhall fill without turning ſideways, and this is very eaſy. A large Hole is to be made for this Purpoſe in the Middle of the Bottom of the Pail, and a Cover is to be fitted to it in the Manner of the Sucker of a Pump; in this Caſe, as ſoon as the Bottom of the Pail reaches the Water, the Hole will open and the Bucket will preſently fill; then, as ſoon as it is drawn out of the Water, the Cover ſtops the Hole and it comes up ſecurely. This prevents the ſinking of the Bucket, and a great deal of Trouble.

Any Wheelwright will be able to make ſuch a Wheel; and it will be a very good Method to make it with Teeth, and with a Ledge of Wood ſo falling upon it, that as the Servant moves forward in the drawing, nothing ſtops the Pail; but as ſoon as it is high enough, the Ledge of Wood bearing againſt the Teeth, ſtops it. The Structure of a common Jack Wheel will explain this eaſy Piece of Workmanſhip.

The Way to be moſt expeditious in raiſing Quantities of Water by this Method, is to have a Receiver for a great deal of Water placed ready near the Well, and a Trough long enough to reach from the Ledge of the Well to it. This Trough is to be placed under the Bucket, and it will be eaſy by faſtening a Cord to the Cover of the Hole within the Bucket, to pull it up when the Trough is ſet under; thus the Bucket will both fill and empty without turning down, which will be a great Eaſe and Convenience in ſuch a large Size.

This is a Method by which the Farmer will be able to ſupply his Stock always with Water, in Seaſons of Drought, but it is expenſive, and takes a great deal of Time to begin and finiſh it. Therefore as the Cattle might be loſt while it was doing, if never thought of till wanted, the Farmer in a large Concern, where he ſees there may be a Neceſſity of ſuch Aſſiſtance, ſhould have it ready in Time, and at the Expence of his Landlord; for the Well will ſerve ſucceſſive Tenants, and therefore is not to be the Charge of one.

Where ſuch Contrivance is wanting, let the Huſbandman look carefully about, and ſee if there be no Place in the higher Ground where the Water is detained. Ponds on the Tops of Hills are not uncommon, and where there is Water above, it is eaſily brought down to be of Service. In this Caſe his Care ſhould be to keep the Pond at the Top well ſheltered and well bottomed, that all that comes to it may be preſerved in it, and then Pipes are to be laid from this to the Place where Water will be moſt needed. One ſhould be always carried to the Houſe, and another to a Place where the Cattle may be conveniently watered. Thus will a Supply be often preſerved, when all others, except deep Springs, fail; and in this Way there is nothing of the Trouble of drawing up and emptying, as in the others.

It is frequent that Springs riſe on the Tops of Hills: theſe will fill ſuch Ponds, and afford a laſting Reſource: but without theſe the Aſſiſtance of ſuch a Supply is very common. I ſhall refer the Reader about London to one familiar Inſtance. On the Right Hand Side of the Road to Harrow, about a Mile from Paddington, is a very conſiderable Farm occupied by Mr. Godfrey. It is near the Top of the Hill. After a few more Paces you arrive at the Top, which is a Flat of no great Extent, dropping off every Way again: there is a little ſinking in this Ground toward the Middle of the Flat, and in that Place is a large round and deep Pit. This is always well ſupplied with Water; and from this Mr. Godfrey has Pipes laid, which go to his Houſe, and afford a continual Quantity for all needful Uſes.

At firſt Sight a Perſon might imagine there was a Spring in this Place; but I have examin'd and found it otherwiſe. The Soil is all a hard firm Clay; by this Means the Pond is as well fenced to keep Water as if it were leaded; and though expoſed ſome Part of the Day to the Sun, its Depth to the Surface ſhelters it very well from the Wind. It receives the Water no other Way than from the Rains that fall upon the Flat, at the Top of the Hill; but the Soil there being all the Way Clay, it takes almoſt all that falls on the whole Surface. Very little is abſorbed by the thin Coat of Mould which covers the Clay in that Place, and the reſt ſinking toward the Pond, is received into little covered Drains, that diſcharge themſelves into it.

Nature has, in many other Caſes, given the ſame Opportunities of ſupplying a Farm with Water, in Times of Drought: it were well if others had made the ſame Advantage of them.

This is the moſt rational and beſt Method of bringing Water from a higher Place down to the Farm; on the other hand it may often be neceſſary to bring it up from a lower, when the Cattle cannot of themſelves get at it. In this Caſe Recourſe is to be had again to Mechanicks. There are various Ways of getting Water up from below, ſome ſuited to larger and others to ſmaller Purpoſes: of all others the moſt convenient to the Farmer will be the Persian Wheel, which we have named before. This is conſtructed at a moderate Expence, and will laſt a long Time, being not liable to be often out of Order; and the Quantity it will raiſe is ſufficient for all poſſible Purpoſes in the Service of the largeſt Farm.

CHAP.

CHAP. VIII.

Of the Signs and Notices of Drought to be observed by the Farmer.

AS a Continuance of dry Weather in the Heat of Summer is the Source of this terrible Calamity to the Husbandman, he will naturally be terrified with the Apprehension of it, oftener than injured by the Thing itself. It will be natural for him, on any long Series of hot and dry Weather, to fear he shall not have Showers; and as he will be in the right to provide against the Disaster as early as he can, it will be of great Use to him to make a rational Guess, whether the dry Weather that at any Time alarms him is or is not likely to continue.

We smile at many of the common Prognosticks of the Weather; and acknowledge that those which are better founded are uncertain: we could therefore have gladly dropped the entering upon the Subject at all, but that we think it may be of real Service to our Readers; therefore we shall lay down such Observations, as are most likely to inform the Husbandman what he is to expect; cautioning him never to have Recourse to them but in continued dry Seasons, and then to judge of them as we deliver them, not as certain, but in some Degree probable; accepting them as the best Guides he can obtain, and therefore consulting them for Want of such as would be less dubious.

Prognosticks of Weather are seen in animal and in vegetable Bodies; not only such as are living, but in the Parts and Preparations of them when dead.

It is plain from repeated Experience, that Birds, Beasts and Fishes are warned of the Changes in the Air, by Notices that either do not reach us, or that we do not regard.

We see in the Weather Glasses the great Effect of Changes in the Air; and we perceive it also in many other natural Instances.

These all shew that Changes of this Kind affect both solid and fluid Substances; and therefore that we may seek for them, and observe the Marks of them, as Notices of succeeding Changes or Continuance of Weather in almost every Object that is before us. In Things inanimate we can only perceive them by Examination. A Board will swell against Rain; but if we do not observe and examine it we shall not see it: but in living Creatures their Actions shew what they feel; their Bodies are affected by the Changes of the Air, and they are guided by Instinct, more certain than Reason, and more invariable; therefore we may observe their Actions as Prognosticks of what will happen in Consequence of what they feel.

These Creatures are the more sensible of all Changes in the Air, because they live exposed to it, and can feel no Changes but what are natural: Mankind who live in Houses alter the Temperature of the Air by Fires, and are by that Means made incapable to judge of its real Variations. The Change from the Air of a Room with a Fire, to that of a Field or Garden, is so great, that it quite drowns the small Variations which may have happened in that free Element; rendering them commonly imperceptible, and when they are greatest of all, confused and uncertain.

For these Reasons we must conceive that other Creatures are more sensible of these Changes than we; and as they have Motion and Voice, we are to watch both for the finding out their nicer Feelings.

Slight Changes in the Air are so frequent and so sudden, that nothing can be expected to be thus made out from them: therefore let the Farmer never seek after these Signs of them, but when a settled and continued Season of one Kind has made it natural and necessary for him to look after every Notice of another.

In this Case of Danger of Drought, if there be Herons in the Neighbourhood let him observe their Course. This Bird delights in a lofty Flight, and will indulge itself in it, when Opportunities of satisfying its ravenous Appetite do not call it lower. When the Heron flies high in the Middle of the Day, it is a Sign the Dry Weather will continue. The Food of this rapacious Bird is principally small Animals that haunt about the Waters. Fish are its Delight when it can catch them; but they are too swift in their Motions for its general Supply: Frogs, black Snails, and other such Creatures, are its common Prey. The Dews of the Night call out these early in the Morning, and this is the Heron's Time of preying. When the Earth grows dry, and the Sun hot, they retire into their hiding Places, and the Bird indulges himself in his airy Flights. This is his Custom in dry Weather: but if there be a Change for Rain, these Insects feel it, and they crawl out of their Holes by Day. The Heron feels it also, and Instinct guiding him, he descends in Search of them: his Flights are low, and he is frequently stooping.

Upon this rational Principle depends the Sign of Drought from the Heron's flying high; and it is one of the most certain that are to be gathered from the Bird Kind: but it is not on any one of these the Farmer is to build his Opinion: Things doubtful are no Way so well confirmed, as by being supported one by another.

All Beasts are rendered faint and languid by a Continuance of hot dry Weather; and while they continue so, 'tis a Sign the Cause will continue. The Farmer, to know what he is to expect in this Matter, should watch the Actions of his Stock: while they seem inactive and dull; while they rise late to their Food, and eat it carelessly, it is a Sign the Drought will continue. They feel the first Approaches of Rain; and before the Farmer sees the Clouds toward it in the Sky, he may know it will happen by their Conduct. After a long Series of dry Weather, the Sheep will rise an Hour before their Time to feed. When Rain is coming they and all the other Cattle will feed heartily: their Motions will be brisk, and the Cows and the Oxen will toss up their Heads and snuff the Air with Pleasure.

When the Farmer has these Notices of Rain from the Bird and Beast Kind, he may give up his Fear of Drought; for Showers rarely fail to follow. Many more might be named, but these after a long Drought are certain the most.

To these Signs from the Birds and Beasts we may

may add ſome from Fiſh and Inſects, but they are not of equal Certainty; they will ſerve as a Confirmation of the others, though leſs authentick alone.

If the Farmer has a Pond with Fiſh, let him from time to time look into it carefully. If his Fiſh keep out of Sight the Drought is likely to continue: and on the other Hand, if they come up to the Surface after diſappearing many Days, he may imagine there will be Rain. Fiſh love Air, but it muſt be a moiſt Air; and they feel it even under Water.

This is another though a leſs Reaſon of the Heron's leaving his high Flight when Rain is coming. He has no Chance for Fiſh while they all keep in the deep Water; but when they riſe in the Shallows he may ſurpriſe ſome of them.

Eels keep all Day deep in the Mud in dry Weather; but they will often put up their Heads on the Approach of wet, and ſometimes crawl on the Surface. Theſe, more than any other Fiſh, are the Prey of the Heron; and this is another Cauſe of his leaving the airy Heights of his dry Weather Flight when the Approach of wet calls them out. Added to Inſtinct here may be the Aſſiſtance of Eyeſight. The Sportſmen know from what a Height Hawks will ſee: the Heron has Eyes of the ſame piercing Kind; for all Creatures have their Organs ſuited to their Uſes: and the Sight of Fiſh riſing to the Surface, and of Frogs crawling out of their Holes, may bring this Bird down, as well as the Guidance of Inſtinct upon his Feelings.

In long Droughts Worms penetrate deeper into the Ground. This is natural, for they muſt have Moiſture: their very Skins alſo dry up when expoſed to a parching Air, and it is certain Death to them. In theſe Continuances of dry Weather they rarely come Abroad: and while the Farmer ſees nothing of them or their Caſts upon the Earth, he has Reaſon to fear the Drought will continue.

Theſe are the principal Signs of continued dry Weather from living Creatures; but there yet remain other Obſervations for the Huſbandman on Things inanimate on Earth, and in the Skies: all theſe he is to obſerve; and joining them with the others he will ſeldom be miſled in his Opinions.

When all the Wood Work about his Houſe and Yard moves looſe and eaſy, and the more ſlight or coarſe Works rattle in the Joints, it is a Sign the dry Weather will continue; and when the Surface of Marble or ſmooth Stone in Chimney Pieces and Floors is perfectly dry, it is alſo of the ſame Purpoſe. We ſpeak here of Rooms in which there are no Fires; for they will change the Nature of all theſe Signs.

With Reſpect to the Heavens let our Farmer obſerve the Sun at his Riſing; for he is an ill Huſbandman that is not up before him: if he riſes ſmall and blue, too bright to be looked upon, and in a clear Sky, there is all the Appearance imaginable of a continued dry Time. When there are rainy Vapours in the Air, they enlarge his apparent Bigneſs, and ſhew him of a fiery Colour. In great Droughts the Sun conſtantly riſes of the ſame Size as he is ſeen all the Day, and of the ſame intolerable Brightneſs.

At Night let the Huſbandman watch the Moon and Stars: if they are bright and clear, there is the ſame Reaſon as from the Sun's Brightneſs to believe the dry Weather will continue. If the Horns of the new Moon look particularly ſharp, that alſo is a Sign of its laſting.

All theſe Obſervations depend upon the ſame Principle, the Clearneſs of the Air through which we ſee them. To ſpeak to a Philoſopher we ſhould only ſay, a clear Air in dry Weather is a Prognoſtick of its continuing dry: but to the Farmer we explain the Matter by Inſtances.

The Clouds may give ſome Signs of Drought alſo; though from their fleeting and inconſtant Nature, leſs Dependance is to be placed on them than on the other Tokens. Thus if the Sun ſet red, that is, if there be a light red Sky in the Weſt at Evening, it is a very ſtrong Sign of the Continuance of dry Weather; eſpecially if the Eaſt be free from Clouds at the ſame Time. In the ſame Manner, when only a few light looſe Clouds are ſeen in the Weſt at Sun-riſe, and they ſoon diſperſe, it is a Token of the Continuance of the dry Time.

The laſt Thing we ſhall direct the Farmer to obſerve as a Guide to judge of the Continuance of dry Weather, is the Wind: let him watch this carefully. The North and the Eaſt are the fair Weather Winds in England; the South and the Weſt thoſe which often bring Rain. When the Wind ſeems ſettled in one of the dry Quarters, or in changing goes only toward the other, there is the greateſt Probability that his Birds, Beaſts, and all his other Obſervations, have told him true; and that he is to expect a Seaſon of Drought: and in this Caſe let him prepare for it.

There are leſſer Obſervations to be made for the foreſeeing ſudden Showers and Days of clear Weather in the common changeable Courſe of Things: theſe we ſhall treat of as leſſer Signs under the Article of Rain; but in this Place we are conſidering a Thing of much more Importance than thoſe ſudden Variations.

We have laid down a Number of Obſervations from different Sources, all tending to the ſame Point, the long and ſettled Continuance of dry Weather; the Conſequence of which in the Extream is Drought. When the Farmer ſees one of them, let him examine whether the Reſt hold good; and if they all do, prepare againſt the Accident they threaten; let him ſecure and preſerve his Water upon theſe firſt Notices, and if they continue any Time, as the preſent Examples ſeem to foretell they will, let him begin ſeaſonably to obtain ſuch Recruits as will be abſolutely neceſſary; and in this let no Evaſion take him off, nor any Expence deter him. His Neighbours will be in the ſame Condition with himſelf, ſo they cannot ſupply him; and it is very probable that the Conſequence may be the loſs of great Part of his Stock.

CHAP.

CHAP. IX.

Of Rains.

WE are here talking of the Extreams of thoſe Things, which are in themſelves, when properly moderated, of the utmoſt Advantage and Uſe: Heat was the laſt named, and Moiſture is to be treated of in this Place. Both are needful to the Growth and thriving of Plants; and they are indeed the two great Requiſites to that Purpoſe: but both may be deſtructive, both to the Crop and Stock of the Farmer. 'Tis a Proverb, that the beſt Things when improperly conducted may be the worſt; and it is in nothing ſo true or ſo evident as in theſe Articles. We are not to arraign the Wiſdom of Heaven, which doubtleſs when it ſuffers theſe Evils to fall upon the Huſbandman, by that very Sufferance prevents greater: but in the plain Face of Things, Heat in Exceſs is fatal, becauſe it brings on Drought; and Rain in Exceſs is deſtructive, becauſe its Conſequence is Inundation.

'Tis not impoſſible, that by the vaſt Rains of this late paſt Winter we may have eſcaped the Earthquake that overthrew Lisbon, and ſhook as it ſhould ſeem a third Part of the Globe. This Conſideration may ſtop our Mouths from exclaiming againſt that Providence, which in Mercy to us has been thus ſeemingly cruel: but it is not to with-hold our Hands from relieving us from the Conſequences of this great Fall of Waters. They are not the leſs hurtful to the Farmer, becauſe they may have ſerved ſo great a Purpoſe in the Order of Nature; therefore he is to conſider the Remedies for their Conſequences.

All Lands will receive Damage by violent and exceſſive Rains; but thoſe moſt which lie loweſt. From the higher Grounds they waſh away the Manure that may have been laid on, and even their fineſt Mould; this therefore muſt be repleniſhed: but from the lower Grounds it is neceſſary to remove them, or they become Ponds or Bogs, not Meadows, Fields or Paſtures.

This is an Accident the Farmer ſhould always foreſee and provide againſt. It is more frequent by far than Drought; and with Neglect every Year may bring it upon him.

Every Piece of Ground has ſome Declivity or Deſcent: his Buſineſs is to find that; to cut Channels in Readineſs for the Reception of the abundant Water that ſhall fall upon the Ground, and to lead them according to that Deſcent to diſcharge themſelves at the loweſt Place.

We have ſhewn in the Words of an ingenious and worthy Correſpondent, how accidental Floods may ſerve the Purpoſes of the Farmer in ſhewing him the true Deſcent of his Ground: theſe he is always to obſerve, for nothing will ſo well inform him how to carry his Drains. This Subject having occaſionally treated on before, we ſhall not repeat any Thing here.

Beſide the Damage that may ariſe to the Huſbandman by the heavy and continued Rains of Winter, there are Seaſons at which every Shower may reaſonably alarm him. Theſe are particularly the Times of Hay making and Harveſt. He is for the Succeſs of theſe Operations to ſeize upon every good Hour that comes; and it will be of the utmoſt Importance to him on this Account, to form ſome reaſonable Conjecture what Weather is likely to follow.

It is a Matter of Indifference whether he bring the Scythe into his Meadow, or the Sickle into his Field, one Day or another. There is a Time at which the Graſs has moſt Subſtance, and the Grain is richeſt in the Ear; but this is not limited to a Day in theſe, as in ſome other of thoſe precarious Crops we have named.

The Farmer may be tempted by fine Weather to begin both ſomewhat ſooner than he intended; and he may, on the threatning Preſages of Rain, defer them ſome Days. It is therefore of the utmoſt Importance for him not to deceive himſelf concerning this Article: and as it may with ſome tolerable Degree of Certainty be foreſeen by many Means, we ſhall give here all that have Reaſon for their Foundation, among thoſe Things that are generally ſuppoſed to forebode Rain.

We ſhall here, as in the foregoing Chapter, ſelect thoſe Signs for which there is Foundation in the Laws of Nature, and which we have known Experience to confirm; paſſing lightly over the others, and utterly rejecting the Fancies of weak and credulous People, which have too long impoſed upon the Injudicious.

CHAP. X.

Of the Signs and Notices of Rain to be obſerved by the Farmer.

IN general the oppoſites to all thoſe Things we have ſet down as Signs of Drought are to be underſtood as Notices of Rain: therefore the Farmer recurring to our laſt Chapter on Drought, will there ſee the many Things that ſtrongly preſage Rain, as the contrary of thoſe there named. Thus when the Heron flies low; when the Cattle riſe early to their Eating; when Fiſh ſwim on the Surface of the Water, and Worms crawl frequently out of the Ground; when Wood ſwells, and Marble is wet on the Surface; when the Sun looks big at his riſing, and the Moon and the Stars appear dull; when looſe Clouds fleet about in the Weſt in a Morning, and do not diſperſe as the Sun advances againſt them; and when the Wind is South or Weſt, and changes only from one to the other of thoſe Quarters, Rain is to be expected.

Theſe are the Oppoſites to thoſe Signs we have given of continued Drought: therefore having explained their Cauſes ſeverally there, we need only recapitulate them here to the underſtanding Reader.

To theſe we ſhall add many more Accidents in Nature, which may be underſtood as general Preſages of Rain; and which often precede the lighteſt Showers.

Birds feel the Approach of Rain as other Changes in the Air, and this always with Pleaſure: a moiſt Air ſeems beſt ſuited to the Nature of all the Kinds that are wild with us; and particularly to the Water-Fowl. It alſo brings out of their

their Lurking-holes the Myriads of Insects which are their Food. The Farmer should watch the Fowls of his Yard, and the wild Commoners of Nature, at all those Times when he fears Rain.

If his Geese and Ducks prune themselves, seem more than ordinary chearful and lively; and the Crows in their hoarse Voice caw from the Tops of the Trees, he is to understand it as their rejoicing at a damp Air, and the Approach of Rain: these last named Birds are extremely sagacious. When they fly about tossing up their Beaks, and are very noisy, the Rain is coming: and when they stalk by the Sides of Brooks and Ditches, it is near at hand.

When Swallows fly low it is a very well known Signal of Rain, and is founded on the plainest Reason. The Food of these Birds is little flying Insects, and all these unable to bear up against the Weight of the Air when loaded with Damp, fly low. The Eye sees this, and Reason confirms it.

The Crying of Peacocks is another known Sign of Rain: it is that Bird's Note of Joy. His Voice is hoarser than the Crows; but it is, like the cawing of that Bird, a Sign of his Satisfaction.

Among the Beast Kind Sheep shew the first Signs of perceiving the Approach of Rain; it makes them sprightly: they leap about and play with one another. The Ass foretels it by his braying, which is also his Note of Satisfaction; and the Cows and Oxen by tossing up their Heads and licking their Snouts.

These are the Signs of Rain being gathering in the Air; but when it is just at hand Cattle give other kind of Notice. They flock together to the Hedges, and seek Shelter under Trees where they may stand till the Shower is over, and whence they may proceed to the Grass sweetened by this Sauce from Heaven.

The very Insects may be of Use in this Way to the Farmer; their tender Bodies give them Notice of the Changes in the Air long before Men perceive it. The Bees keep within their Hives, and the Ants leave their busy Motions, and retire deeper into the Ground. They carry with them those Cases in which the winged Sex are lying for their Change, as the winged Insects of all Kinds do. These common People call their Eggs; but that is an Error.

From the Animal Kind we shall lead our Farmer for Presages of Wet to the wild Weeds of the Field, and to the common Products of his Garden. The Poet speaks of the closing of the Flowers of common Marygold at Evening: he calls it

The Marygold that goes to Bed with the Sun,

and this, and all the other Flowers which have that Quality, as there are very many that have, shut up in the same Manner more or less when Rain is coming.

The youngest Flowers, or those most newly opened, have this Quality the most sensibly; and they are to be watched for it: dry Weather opens them fully; and as wet is nearer or farther off, or as there is more or less of it in the Air, they firm or draw together their Leaves in a more close or loose Manner.

In the Corn Fields the Farmer will meet with a little Plant famous for many Virtues, its Name is Pimpernell, he will know it by its small bright red Flowers: these open in dry Weather, and shut up against Rain: Wet may be foreknown a whole Day before it falls by this Flower; and the Country People in some Places are so sensible of it, they call the Herb their Weather Glass.

In the Pastures he will see many Heads of Dandelion gone to Seed: these are so many Globes of Down in fair Weather; but against Rain they contract themselves, and shew a very plain Mark of its coming.

From his Pasture let the Farmer look into his Clover Field, and he will find another Mark of Rain which has been observed these two thousand Years: the Clover when Rain is coming stands more upright and firm than at other Times; the Stalk is swelled and stiffer. This is true in the same Manner with many other Plants, but in none so distinctly.

From the Field if we bring him into his House, he will there find also the Signs of approaching Wet very frequent and very familiar. All Wood swells with the Wet, and the softer Kinds the most. Deal, which is the Timber of the Fir-Tree, and is one of the softest of them all, swells most of all; and its common Use in Houses gives Opportunities of seeing it. Doors will not shut; for both the Posts and the Boards of which the Door is made swell: Window-Shutters stick, and Boxes are hard to shut or open: Drawers of the same Wood also stick in their Cases; and those of other Wood do the like in Proportion to the Kind.

From these Things of common and small Concern, let him turn his Eyes up to the Heavens. We have observed, that the Sun's looking red and large is a Sign of Wet; and let him mind the Clouds that accompany this Appearance, for they will not only confirm that Rain is falling, but in some Measure shew the Time when it will come.

If Clouds presently after such a Rising of the Sun gather in the Sky, and the Air appears thick and watery, then it will presently rain; and the hotter the Weather, the sooner the Rain is to be expected from his Appearance.

When at Sun Rise, or soon after, there be a Circle or Part of a Circle of a blueish or whitish Colour about the Sun, there may be expected Rain some time within the Day.

We have before observed, that a red Sun at rising is a Sign of Rain; and the same is to be added concerning its looking dull and white. The natural Colour of the Rising Sun in a clear Air is the same that it has at Noon Day, a deep fiery Blue, which the Eye cannot look upon a Moment. When he is dim and faint, and looks white, it is owing to watery Vapours in the Air, and Wet is near.

If the Moon have a large Circle of a whitish Colour round her at a Distance, it is another Sign of Rain: and when the Stars look larger than usual, and fainter, and twinkle less, it also presages Wet the next Day: this Observation of the Stars not twinkling so much, the Farmer is to understand is confined to the fixed Stars; for the Planets, though larger than they, never twinkle at all.

The Clouds give also many Prognostications of Wet. When there are many small ones scattered

tered about the Weſt in an Evening, Rain is to be expected the following Day.

It is uſual at theſe Times to ſee the Clouds large, thick, and maſſy, ſo that a fanciful Perſon may imagine among them Reſemblances of Rocks and Towers. Theſe are Signs of a great deal of Rain, and often of Thunder.

The Rainbow is a Source of many Prognoſtications reſpecting the Weather; and is not ſufficiently underſtood. In general it beſpeaks a Change: if it appear after a great deal of dry Weather, it foretels a great deal of Rain; but when we ſee one after a great deal of Wet, we may expect fair Weather.

A bright Rainbow in the Eaſt is uſually followed by a great deal of Rain.

Miſts from Waters afford alſo a regular and very certain Prognoſtick of ſucceeding Seaſon. When they are thick in the Morning, and preſently after diſperſe, they are Tokens of fair Weather: but when they riſe to the Neighbouring Hills, and hang in the Air, they uſually preſage Rain, though commonly at a Day or two Diſtance.

Theſe are the principal Notices from the various Works of Nature, which the Farmer is to obſerve as threatening Rain, during his Summer Works; and as it will be of the greateſt Conſequence in Reſpect of theſe to know from all Methods when he is to expect proper Weather, as well as when he is to fear ſuch as will be hurtful: we ſhall add thoſe ſeveral Appearances from all Kinds of Objects, in Conſequence of which he may reaſonably promiſe himſelf a fair Seaſon, for the cutting, drying, and carrying in his ſeveral Products.

CHAP. XI.

Of the ſeveral Signs of fair Weather.

WE have before ſpoke of thoſe continued dry Seaſons in hot Summers, which bring on Drought and are in the higheſt Degree detrimental to the Farmer; but what we are here to ſpeak of is, that Kind of fair Weather which comes in ſeaſonably, and laſts properly and in a natural and uſeful Manner: ſuch clear Seaſons as come between the ſhowery Times, and ſerve for the gathering in the Produce, without Wet.

The ſeveral Signs by which he may probably know ſuch Seaſons are approaching are theſe. A clear Sky in a Morning, and a bright Sunriſing in it, are the natural Tokens of a good Day; and when at Evening he ſets in a light and bright red Sky, and without heavy Clouds, there is Reaſon to entertain good Hope of the next.

Next to the Sun the Moon is to be obſerved. At all Times when ſhe looks bright and clear, and has no foggy Circles round her it is well; but the greateſt Promiſe is from her Appearance a few Days old. Let the Farmer, whoſe Harveſt Time approaches, watch well the new Moon. If he ſee her Horns ſharp, clear, and fine, he may reaſonably expect fair Weather till her Full; and probably enough it will continue much longer.

The Stars give the ſame Token of fair Weather as the Moon, and juſt in the ſame Manner. When they look very ſharp and bright, and twinkle ſtrongly, there is a clear Air, and it is like to continue.

White, ſmall, and ſcattered Clouds at the North Eaſt, are alſo a Token of ſeveral Days fair Weather.

On Earth the Farmer will find Means of Information in this important Article, as well as in the Heavens. Let him look to the Hills, and if he ſees their Tops clear he may expect bright and ſerene Days: even the Stone and Brickwork of Buildings, in ſome Degree, gives the ſame Notice to the Eye. It is ſeen more clear and diſtinct in the pure Air, that brings in fair Weather, than in ſuch as is full of watery Vapours, and precedes and preſages Rain.

Light Miſts, of a white Colour, gathering early in the Morning over Waters, and ſoon diſperſing, are Signs of fair Days.

If a Shower happen, and there be a Rainbow, let the Farmer watch it carefully; if the blue be a ſtrong Colour, and the yellow be bright, it is a Sign of clear Weather quickly following.

When Gnats ſwarm in an Evening, and the Glow-worm crawls Abroad at Night, good Weather generally follow. Theſe tender Inſects dread the Rain as fatal to them, and hide themſelves when Inſtinct gives them Notice of its coming. Their ſwarming Abroad therefore is to be obſerved as an Information of fair Days ſucceeding, given to Mankind by their Actions. Inſtinct guides them; and Man's Reaſon is to be directed by it.

The Bee is alſo a ſure Director. Her little Organs feel the Approach of Wet; and keep her Priſoner in her Hive, or limit her to ſhort Excurſions when it is near: therefore when ſhe flies far, and returns late, good Days are coming.

Next let our Huſbandman obſerve the Birds. When the Kite and the Swallow fly high good Weather is coming. They can ſee their Prey to a greater Diſtance in that clear Air that preſages fair Time; and they love lofty Flights.

When the Sea Birds leave the Shore; and when the Owl hoots ſoftly, gently, and compoſedly, fine Days may be expected.

Fiſh and Inſects join alſo in giving theſe Tokens. When the Roach and Dace leap up out of the Water, and when the Spider hangs its light Webs in the Air, fair Weather is comeing: Experience, more than any certain Reaſon, eſtabliſhes this Token from the Fiſh. As to the Inſect it is plainly the Direction of Inſtinct. Its tender and expoſed Body feels the Change of Air for dry Weather; and Inſtinct directs it on that Notice, to venture out its Threads, becauſe there will be nothing to hurt them.

Laſtly, we ſhall give the Huſbandman a Notice which he is to regard more than any of the preceding, becauſe it anſwers doubly, as a Promiſe of fair Weather for the preſent, and a Denunciation of Rain ſoon after. This is that thick dark Sky we ſometimes ſee for a Continuance of Time, without either Sunſhine or Rain. This is a Thing that frequently happens in England about the Harveſt: and the greateſt Regard ſhould be had to it: it is an unerring

erring Rule, that such a Sky is followed by some fair Weather, and that Rains come soon after. Therefore let the Farmer manage his Business accordingly.

He needs not be afraid of sudden Rain, where there is such a Sky. He may proceed in his Employment, assuring himself that though Rain will follow, there will be an Interval of fair between, which will serve at the same Time to finish his Work, and to give him Notice of Wet to follow, from which he is to guard his Crops.

CHAP. XII.

Of Hail.

HAIL is an Accident much more dangerous to the Gardener for his forward tender Crops, than to the Husbandman, whose Products being at all Times exposed to the Weather, are more hardened: when it happens to be very violent, and the Stones very large, it will do him some Damage; but it is less to be foreseen, and less to be guarded against than any of the other Accidents of Weather. In the warmer Parts of Europe it is often terrible to the Husbandman, because the Heat brings his Crops as early forward in the Field as ours in a Garden: but neither there can he foresee or guard against it.

Those Storms in those Countries are less frequent than in ours, but sharper. The Roman Catholick Religion established in most of those Kingdoms, throws them into the Mockery of Processions, and solemn Rites; and as these Storms never are very lasting, they attribute the ceasing of them to those Solemnities. God, who commissions all these Things for Purposes unknown to Man, though intended for his Benefit, is not to be averted from his settled Intent by their ignorant Prayers. The Pagans who beat Drums when the Sun was eclipsed, were about as wise, and had as much Share in the bringing Light again. Submission under Afflictions, and general Prayers, are the Dictates of Reason in these Cases: the Language of the prudent Heart should be, "Thou knowest what "is best." And the Christian Resignation is, "Thy Will be done."

All the Husbandman can do in these Storms of Hail is, to watch whether they seem to be slight and common; for in these, as we have said, there is very little Harm to him; or whether they threaten to be very terrible: in the former Case he is to leave all to Nature; and in the latter he should be quick in driving under Shelter, all such Parts of his Stock as could be hurt by it; his Lambs and other young Creatures. His Crop he can no more shelter than he can remove it, therefore it must take its Chance; but as we have observed the common Season of Hail is at a Time when that is not of a Growth to suffer any great Damage.

As we have, on all other Occasions, endeavoured to make the Farmer acquainted, in some Degree, with those several Things wherewith he has any Concern, we shall add here a succinct Account of the Nature of this Substance.

He is acquainted with the Nature of Rain, which is Water raised in Form of Vapour by the Sun, and falling again in Drops. These Drops often pass through a considerable Depth of Air, before they reach the Ground; and it sometimes happens that they are frozen by the Way. Every one knows what a frozen Drop of Water must be: it can be no other than a small roundish Piece of Ice; and whoever will examine Hail-Stones will find them such. Observations have been made, in particular Cases, of Hail-Stones of odd Shapes, as long, or flat and thin, and Star-like, but all these are uncommon. With Respect to the long and flat, they seem only the Effect of various Degrees of freezing; but the Star-like Hail, which is observed to have six regular Rays, is of another Origin. Those who have examined these Matters nicely, will find no Difficulty in the accounting for that Shape: it is the natural Form of pure Flakes of Snow. Therefore, as the common Hail consists of Drops of Rain frozen in their Passage through the Air; this is composed of Flakes of Snow, frozen to the Hardness of Ice, in the same Manner. What the more confirms this is, that these starry Flakes of Hail are always thin and light.

Though these fall with less Force and Weight than the others, they are often attended with more Damage, especially to the Gardener; for when they are driven before a violent Wind, their sharp Edges cut off the Blossoms of Fruit Trees like so many Knives.

A very good Practice in Gardens on this Occasion is, to stick in Pieces of Furze Bush among the Branches of the Fruit Trees, to keep off the Hail from the Blossoms. We name this here, because it may be transferred, if there be Occasion, to the Field, if the Farmer have any young Crop for which he is in Fear from Hail Storms; he may with little Labour or Expence stick up large Furze Bushes among it at certain Distances, which rising above the proper Growth will, by their bushy Heads, defend it from the Fury of these Storms in the same Manner as in the other Instance.

This is a Caution never needful, except upon particular Occasions, and they are not to be foreseen. Indeed this is the Misfortune with Respect to all the Damage by Hail, but when there is Notice, as there commonly is, of any very violent Storm, it is worth the Trouble of a little Care. The driving in of Cattle and Poultry is the Principal; and 'tis better this should be done when there was no real Necessity twenty Times, than once omitted when there was.

Mischievous Storms of Hail generally are of small Extent, and may be foreseen a little before their coming, by a thick black heavy Cloud, with Chillness in the Air and Wind.

Toward the End of April, in 1697. there was one of these terrible Storms in Cheshire. A black Cloud of this Kind foretold its coming about a Quarter of an Hour. This was Time enough to have got in the tender Cattle, but the Farmers were not aware of the Danger, and they suffered terribly. The Breadth of this heavy Cloud was about two Miles, and the Course it took before it dissipated was sixty Miles; along all this Tract there was made the most terrible

Havock of every Kind, but not the leaſt beyond or beſide it. The Hail Stones in this Storm were as big as Hens Eggs, Geeſe Eggs, and ſome of the full Bigneſs of a Man's Fiſt. They were Pieces of clear, tranſparent, and very hard Ice, with a white Kernel in the Middle, that ſeemed a little Lump of Snow. Some of theſe vaſt Hail Stones were quite ſmooth, and others rough and ſharp on the Surface. They fell with a prodigious Force, and killed Fowls, Lambs, and Calves: beat down the young Crops of every Kind; and in ſome Places, where the Wind drove them ſlanting, plowed up the very Surface of the Ground, and buried themſelves an Inch or two in Depth; Trees were broke and ſhatter'd to Pieces in many Places; Houſes damaged, and many People that were Abroad much hurt.

The Circumſtances of this Storm are recorded in the Philoſophical Tranſactions, and in many other authentick Writings: this, and other Inſtances, are not recited here for Curioſity or an idle Amuſement: they are to ſtand as ſo many Leſſons to the Farmer: Examples of the Loſſes others have ſuſtained by Neglect of driving in their young Cattle; and Cautions to himſelf for a wiſer Conduct. He ſees what Appearances in the Sky foretel theſe terrible Storms, let him be upon his Guard accordingly, watching when they come, and omitting no Care that may prevent the Damage.

There is recorded in the ſame authentick Papers, another Hail Storm the ſame Year much more terrible than the former. It happened in Herefordshire, in the Beginning of May. Thunder and Lightening preceded it, and for ſometime continued with it, as alſo a violent Tempeſt of Wind, that blew both the Lightening and Hail upon ſome Houſes, to their Deſtruction. Nothing could exceed this but the Hail ſent by the Almighty upon the Ægyptians; nor can any Words, according to all the Accounts left concerning it, ſo ſtrongly or ſo truly deſcribe its Terror, as thoſe uſed on the Occaſion in Scripture, "Fire mingled with the Hail ran along "upon the Ground."

In this terrible Storm not only Fowls and young Animals of all Kinds were killed, but ſome of larger Growth; and ſome labouring Perſons in the Fields, who could not reach Shelter, ſuffered the ſame Fate, their Bodies being black and blue, as if beat to Death with Clubs. Oaks were ſplit: the Branches of many other Trees beat and torn down; and Fields of Rye were, in ſome Places, cut down as if mowed off with a Scythe. The Hail Stones in this terrible Storm were of no regular Figure: many of them meaſured fourteen Inches round *, and they ſeemed Fragments of thick Ice.

* *Philoſ. Tranſact.* No. 229.

The Fields of Rye that ſuffered thus ſtood expoſed: others in ſheltered Places were damaged, but not nearly ſo much; this may ſerve as a Caution to the Farmer, and ſhew the manifold Benefits of Encloſures.

To theſe Accounts of Hail Storms in our own Country, we ſhall add two extreamly ſingular in their Kind, vouched upon the moſt warrantable Authorities, the one of theſe was in Flanders, about Lisle, in the Year 1686. and the other in France, ſo long before as in 1510.

In all Obſervations of Hail Storms with us, they have been no other than Pieces of Ice; but in theſe there has been ſomething more. The utmoſt ours have ever been known to contain, has been a little Lump of Snow; but the others have had ſulphurious Matter either in their Center, or in their whole Subſtance. That at Lisle is recorded in the Philoſophical Tranſactions †, and had this Singularity, that the Stones were not only vaſtly large, but appeared duſky in the Center; and ſuch of them as came down Chimneys into Fires, when the Icy Part was melted, and this brown Subſtance was expoſed to the Fire, burſt with a loud Report. Mezeray, in his Hiſtory of France, mentions the other with all its Particulars. In this a black Cloud, ſuch as we have deſcribed, came over the Face of the Heavens, and darkened the Air like Night: in the midſt of People's Terror and Aſtoniſhment, the moſt violent Lightnings and Thunder burſt from it, and Hail began to fall. This encreas'd in a moſt dreadful Manner, and with a ſtrong and ſuffocating Smell, like burning Brimſtone. The Hail Stones this creditable Author atteſts, were more like Pebbles: their Colour blueiſh, and their Hardneſs like Flint, till they ſoftened in the Wet. He gives an Account of their Size, which exceeds all others, and which, if leſs authenticated, could not be believed: he ſays ſome of them weighed a Hundred Pounds. We are not to wonder at the Damage done by ſuch a Storm. He ſays it killed almoſt all the Cattle, Fowls and Fiſh in the County; and vaſt Numbers of the People ‖.

† Numb. 203.

‖ *Mezeray's Hiſt. de France*, vol. II. p. 339.

In Calamities like theſe there can be no Remedy, and there is no Courſe to follow but Religious Submiſſion. They happen very rarely; and the Damage done by ſuch as are more frequent, is not great.

We have ſhewn the Huſbandman what is in his Power to do againſt it; and in general, where he has a tender Crop, that ſtands much expoſed, we ſhall adviſe him to uſe the eaſy Method of ſticking up a few Furze Buſhes. This will not only be a Defence againſt Hail, but it will break the Force and Fury of ſharp Winds, and keep off thoſe cold Rains, they often carry before them. In all Reſpects it is a Practice ſo cheap, ſo eaſy, and ſo certain of doing ſome good, that we cannot but greatly recommend it.

CHAP. XIII.

Of Snow.

WE have in the laſt Chapter conſidered an Accident that never can be of any thing except Hurt to the Farmer; though according to its Nature and Degree, that Hurt be ſometimes greater ſometimes leſs; we are now to treat of an incidental Thing of the ſame general Nature, which yet always may be, and often is of great Advantage. A deep Snow keeps all ſheltered underneath it; and frequently defends a tender Crop from thoſe ſucceeding Froſts which would otherwiſe have deſtroyed it.

We

We have recommended to the Farmer, on ſome Occaſions, the Gardener's Practice of covering his tender Growths in Winter by Haulm, or the dry Stalks of Peaſe, or the like: the Snow often falls ſo favourably as to perform this needful Service much better for him than he could have done it for himſelf; more generally and more univerſally.

It lies thick upon the young Plants, covering them very perfectly, and defending them from the nipping and deſtructive Winds; it all that Time mellows the Soil; and when warmer Weather comes to melt it in, nothing ſinks down ſo gently or ſo gradually. No Water is purer than that of melted Snow, and there is no Method by which Wet gets ſo thoroughly into the Ground.

Nature ſeems to have conſidered greatly the Products of the Earth, in this Formation of Snow. It never can fall but in cold Seaſons; which are the Time in which Plants want Shelter: if the Temperature of the Air about the Surface of the Earth be warm, ſo that there is no Need for it as a Shelter, it diſſolves as it falls, and makes the fineſt watering imaginable.

Snow is in its Nature like Ice, a watery Subſtance congealed by freezing. When the Air is warmer where it paſſes, it melts and falls in ſmall Rain.

The uſual Shape of the Flakes of Snow, we have mentioned in ſpeaking of the particular Kind of Hail which is ſtellated, or compoſed of Rays like a Star. Its moſt perfect Appearance is in Form of a Star of ſix Rays, and its Subſtance clear tranſparent Ice: but this is not its conſtant or certain Figure, the Flakes are frequently imperfect, and often leſs regularly frozen; and all this depends upon the ſlighteſt Accidents; the Height from which it falls, and the Degree of Cold in the Air.

Often there are little Points upon the larger Rays; and not unfrequently the Flakes are altogether ſhapeleſs and confuſed, the Snow having melted in the Air, and froze again.

There have been Inſtances of coloured Snow falling in certain Places, and it has been conſidered as foreboding ſome terrible Calamity. There is Account of a red or bloody Snow by an Italian Signior Saratti, preſerved in authentick Writings: it is ſaid to have fallen near Genoa: but this is very difficult to be reconciled to what we know of the Courſe of Nature. We are ſenſible that Snow is no other than watery Matter, frozen in a particular Manner; and we know alſo that this Water is raiſed in Vapour by the Sun's Heat: now we are ſenſible from what we ſee in Diſtillations, and by various Experiments, that Vapours do not riſe coloured. The ſtrongeſt Tincture of Cochineal will yield a colourleſs Water, if diſtilled; and Red Port Wine yields a colourleſs Spirit. From theſe, and many other Conſiderations, there is Reaſon to imagine that there has been ſome Miſtake in what is written on theſe Subjects. We know that what have been called Showers of Blood, have been no more than common Rains falling in Places where there have been Multitudes of little red Inſects; and that what are called Showers of Frogs, have only been Rain, and have invited thoſe Creatures from their hiding Places. In the ſame Manner it is probable that this Snow was not red as it fell, but that it fell upon ſome red minute Inſects. Signior Saratti ſays, that when ſqueezed it yielded a red Liquor, but this may be accounted for the ſame Way, for if the Inſects upon which it fell were ſqueezed among it, their Juices might turn the watery Part of the natural Snow red.

This may ſerve as an Account of the Nature of Snow, ſufficient for the Huſbandman's Purpoſes of Uſe, or even for his limited Curioſity.

We have obſerved that it is often advantageous to him, preſerving his Crop; but like all other the good Gifts of Nature, it may be hurtful in the Extremes. The ſame Rain that moiſtens the Earth, may drown its Products; the ſame Heat that calls forth the Shoots of Plants may, in a greater Degree, parch and deſtroy them; and in like Manner Snow, which ſhelters his Crop may, in a great Fall, ſmother his Cattle.

He is therefore to act in this Reſpect, juſt as in Regard of Hail. He muſt watch it as it comes, and obſerve whether it will be in the common Courſe, or Exceſſive and Violent. In common Falls of Snow he has nothing to do: but when he ſees a vaſt Quantity on the Ground, and more in the Air, let him drive in his Cattle, and preſerve them from the Danger of being overwhelmed and buried in it, as they often are in thoſe Hollows to which they fly for Shelter.

CHAP. XIV.

Of Winds.

WE have conducted the Huſbandman thro' the ſeveral accidental Attacks to which he may be ſubject from Drought and Rain, Hail and Snow. And we are now to conſider another Subject relating to the Elements, from which he may, without due Precaution, receive great Harm.

Winds are not of the Nature of Snow, a Benefit in the common Courſe to the Land: they are too frequently hurtful. Their general and great Purpoſe is to thin, cleanſe, and purify the Air; and as in this Office, ſo needful to Life, they will often be dangerous to the Huſbandman's Crops of various Kinds, and even to his Buildings, he muſt timely guard againſt them. Let him not accuſe Providence of thoſe Damages he may ſuffer through his own Neglect: God ſaw Winds neceſſary to keep the Air in due Condition, and he has given Man the Uſe of Reaſon to protect himſelf and what belongs to him from their Fury.

The Sea would putrify notwithſtanding all its Salt, if the Winds did not ſtir and move it about: freſh Waters, when they are large, would ſooner ſuffer the ſame Fate, and Men would be carried off by Peſtilences raiſed from the Vapours of ſuch corrupted Maſſes: all this is prevented by the timely Miniſtry of the Winds; and all their Force may be broken with Reſpect to the Farmer, by a proper Plantation of Trees. We know from what Quarters the moſt furious Winds blow, and the Defence is to be prepared

thickeſt

thickeſt there. The Huſbandman is not to leave this Care till the Storm comes, but to prepare in Time, as one who expects it. Trees are of ſlow Growth, but when planted properly they are a very certain Defence.

Beſide this general Care there may be particular Cautions uſed, to prevent Damage on extraordinary Occaſions; and as Storms may generally be foreſeen, like other Changes in the Elements, theſe ſhould be prepared according to the Neceſſity. We ſhall give the Huſbandman a general Idea of the Nature of Winds, and of his proper Defence againſt them; and afterwards add thoſe Signs by which particular Storms may be known to be approaching, and the beſt Care of the Products of the Ground againſt them.

Wind is no other than Air in Motion.

We are ſenſible there is ſuch a Thing as Air, by the Changes we perceive in it, but as it is too fine a Subſtance to be the Object of our Sight or Touch, we only perceive it in the Winds, feeling it by its Motion; whereas, when ſtill it is not perceptible to any of our Senſes, though manifeſt to our Reaſon.

We in this Iſland are ſubject to great Variations and Changes of Wind, from its different Direction and Degree of Strength; but this is not the Caſe throughout the whole World. Between the two Tropicks there is a conſtant and unchangeable Wind, that all the Year blows from Eaſt to Weſt. This Sailors well underſtand, and it is called the general Trade Wind.

About the Coaſts of the Ocean there are conſtant and regular Winds alſo, at certain Times of the Day. Theſe are called Sea Breezes. They blow regularly every Evening from the Sea to the Land; and every Morning from the Land to the Sea.

In many Parts of the World there are alſo regular periodical Winds. Theſe blow one half of the Year one Way, and the other half of the Year the other, without any Variation.

In our Iſlands the Winds play about with great Uncertainty; but in general, where there is nothing in particular to diſturb them, North Winds are moſt frequent in a Morning, Weſt at Noon, and South at Night.

The Winds blowing from off the Sea are naturally moiſt, becauſe they take with them a great Quantity of thoſe Vapours which the Sun conſtantly exhales from the Surface of that vaſt Body of Water. Theſe Winds, when they are gentle, bring only a fine pure watery Vapour; but when the Surface of the Ocean is ruffled by them in Storms, they frequently carry off a Part of the abſolute Salt Water in ſmall Particles. This, when it is carried on Land, is called the Spray of the Sea. It is often very deſtructive, and it will be carried many Miles.

This is mentioned as a practical Caution for the Farmer. Many of his Crops will be injured greatly by this Accident, therefore it is his Buſineſs to plant by Way of Defence; and keep a good Hedge every Way to the Seaward.

The North Winds in England are cold, and the Southerly Winds warm. A Fall of Snow will have Power to change the Courſe and Current of our Winds. A warm Southerly Wind ſhall often be changed into a cold Northerly one by this or by a Shower of Hail. It would be natural to ſuppoſe the Wind changed, and brought the Hail or Snow with it; but Philoſophers, who have examined deeply into thoſe Matters, and particularly that great Chriſtian Philoſopher Dr. Derham, ſhews it to be otherwiſe, and that the Snow or Hail abſolutely change the Courſe of the Wind.

The ſtrongeſt and coldeſt Winds with us comeing from the North and North Eaſt Quarters, it is againſt theſe the greateſt Caution is to be had in planting.

We have given a large Account of the Nature of Trees, and the Manner of planting them, in a preceding Part of this Work, and to that we refer the Reader for his Choice of the various Kinds. The Sycamore has been happily experienced in the Neighbourhood of the Sea, where it thrives very well; and on expoſed Situations the Yew is excellent. It will bear the Expoſure, and delights in the hard dry Soil uſually found in thoſe Places. And though its Growth be ſlow, its Strength makes Amends. Its Branches alſo ſpread excellently for Defence, and are covered with their Leaves all Winter, the Time when Shelter is moſt wanted, and when Trees in general are leaſt capable of giveing it.

After the Yew we may very well name the Elm for this Service; it roots firmly, and is full of Branches. Its Growth is not ſlow, and it is nearly univerſal, for there are few Soils on which it will not thrive.

Hedges are the ſame Security to Fields that Trees are to the Farmer's Dwelling; and the more he ſtands expoſed to Winds the more he is to guard againſt them, by a due Care in this Article.

In Trees planted for this Purpoſe of Shelter to a Houſe, there ſhould be a particular Method of cutting. The Elm will grow to any Form the Planter pleaſes, and indeed ſo will moſt other Kinds. In this particular Service, their Uſe, and the Intent of the Plantation, ſhould be conſidered, as alſo their own Danger. When the Building is much expoſed to Winds, ſo muſt the Trees be that are ſet to ſhelter it: therefore let them be ſo cut as to be leaſt liable to Danger. The Head is the Part over which the Wind has moſt Power, and it is of leaſt Service in ſheltering the Dwelling: therefore in theſe Caſes let the Head be ſmall, and the Tree encouraged to ſhoot out into Branches. The thicker they ſtand the more is the Shelter, and the leſs they are in Danger of being torn down.

When the Huſbandman has taken Care his Dwelling be thus well defended, let him conſider what Part of his Crops will be moſt expoſed to Danger from this Cauſe, and at what Times; and then conſider of the Ways to foreſee and prevent the Miſchief.

CHAP.

CHAP. XV.

Of the Signs by which Winds may be foreknown.

THERE are fewer Preſages and Notices of Wind, than of Rain or Drought; and they are to be obtained from fewer Objects: but therefore the Huſbandman, who wiſhes to preſerve his Crops from all Accidents, ſhould be the more careful in looking after theſe.

If there be a red duſky Sky in the Morning, and the Sun riſes in it white and deadiſh, the Farmer may expect that Day violent Guſts of Wind; and generally there will be ſome Rain with them.

When the Sun is pale at Setting, and goes down behind a thick dead-looking Cloud, there commonly follows Rain that Night; and in that Caſe there is uſually a ſtrong and diſorderly Wind the next Day.

If the Moon look dim and miſty, and have a large hazy white Circle about her, the next Day will be generally much ruffled by Winds.

When the Moon looks particularly bright, but has about her two or three broken Circles, it is a very ſtrong Sign of a Storm.

When the Stars appear more numerous in the Heavens than uſual, and have a particularly lively Luſtre, it foretells a Storm. This as well as the laſt Obſervation regards violent Winds, more than thoſe light Blaſts of ſhort Continuance which are often preſaged by the others.

At any Time when there are a Number of ſmall black Clouds ſcattered in the Heavens, and they move to and fro in a diſorderly Manner, ſtrong and unſettled Guſts of Wind may be expected: theſe are the Winds that do moſt Harm of all to many of the Products of Huſbandry, and therefore the greateſt Regard ſhould be had to this Signal, which gives Notice of their coming, and every Precaution taken in Time againſt them.

When there is a Rainbow, let the Farmer look carefully upon it; not only with Reſpect to thoſe Signs of Rain which we have directed him to underſtand from it, but on this other Occaſion of Wind alſo.

When the Rainbow is thicker than ordinary, it is a Sign of Guſts and Blaſts. When there is a great deal of Red in it, and that is very fiery, it betokens violent Storms.

The Rainbow is naturally a continued Thing; but ſometimes we ſee it interrupted in its Courſe, broken, and as it were ſeparated into many Parts: this is always a Signal of Winds. Moſt of theſe Signs that are perceived in the Rainbow, foreſhew Winds attended with Rain; but that is not conſtant and certain.

Among Animals fewer Notices of Winds are perceived, than of other Changes in the Elements; yet we are not wholly without Notices from them. About the Sea Coaſts in particular, a great deal may be gathered by thoſe Birds which live partly on the Water and partly at Land. The more ſerene the Air, the farther they keep out at Sea. When they ſuddenly make to the Shore together, there is certainly a haſty and violent Storm approaching: and when they keep about the Shore, and will not venture into open Sea, there will certainly be ſtrong Winds that Day.

There is in ſome Places a ſmall Bird, which from its Apprehenſion of Storms they call the *Storm Bird:* this has ſuch certain Knowledge, and ſuch Dread of a Storm, that it never fails to make immediately to the Shore when it is near, on the Approach of Danger; but at open Sea it follows Ships, giving Token to the Sailors of many an unexpected Storm. The Guidances theſe Creatures receive from Inſtinct are very ſurpriſing, and they were intended by Providence not only to be uſeful to themſelves, but to Mankind in obſerving them. This little Bird ſeeks the Shore, when in Reach, before the Approach of a Storm: and when too far from Land, it gets behind a Veſſel for Shelter. The Sailors well know they have a Gale to expect when they ſee it; and the Farmer ſhould have the ſame timely Caution to prepare for the Defence of his Crops in Danger.

CHAP. XVI.

Of the Damages done by Winds to Huſbandmen in their Crops.

PLANTS may receive Injury from Winds at different Periods of their Growth: while young they are ſo tender, that the Blaſt will often chill or ſhrivel them up: when more advanced in Growth, they are more open to its Force by their larger Bulk; and by their ſtanding higher: at this Time they require to be very well faſtened in the Earth by their Roots; and the moſt natural Effect of all others from the Wind is the rocking them about, and looſening of them. This is a Circumſtance very little regarded by Huſbandmen, tho' very much by Gardeners. In this, as in many of the preceding Inſtances, there will be the greateſt Advantage in bringing the Practice of the Garden into the Field. In new planted Trees the Cuſtom is to tie them up to Stakes: and the Stalks of flowering Plants that riſe to any conſiderable Height, are in the ſame Manner faſtened to Sticks. This is of the greateſt Service in both Caſes; preſerving the Roots quiet and ſteady in the Earth. We would not have the Farmer follow this Practice literally, by tying up his Corn or other ſuch Growth, but we would have him take the Caution with him of the Danger there is from Winds, though he uſe another Method of preventing it.

His great Care in moſt Reſpects, muſt be employed in getting ſtrong and thick Fences: in particular Crops there muſt be particular Cautions, which we ſhall name.

Of all the Huſbandman's Products, there is none which ſo often receives Damage by Wind as Hops. There are two Seaſons at which they are deſtructive to this Plant: the Blaſts of the Spring nipping their Buds, and the Storms of the more advanced Part of Summer ſhaking them at the Root.

With Reſpect to the nipping Winds of the Spring, as the Plants are at that Time not much advanced in Height, they are eaſily enough ſheltered by a good high Pale, or a very cloſe Hedge. With Regard to the Winds afterward rocking them at the Root, the firſt Defence is to chuſe a ſheltered Place for the Ground; or plant ſome tall Trees that may ſhelter it: and for all ſucceeding Time the grand Security of the Plants is the fixing the Poles deeply and firmly in the Ground.

Corn is in the ſame Manner expoſed to Damage from Winds, not only when in the Ear by lodging, which principally happens from Winds and Rain together, but while in the firſt Shoots; for the ſharp Winds ſometimes deſtroy in a Manner the whole Produce at this early Period. Experience ſhews, that it is in open Fields the Crop is moſt liable to this Miſchief; and Reaſon therefore ſpeaks, that the ſame Remedy will preſerve it in both States: this is a good Encloſure. Different Soils require different Kinds of Shrubs for Hedges; and we have in a preceding Part of this Work, given the Farmer his Choice of a vaſt Variety of Kinds for this needful Purpoſe; indeed ſo many, that there is not any poſſible Diſadvantage to which his Land can be expoſed in this Reſpect, which has not in Nature its Remedy under this Article, and which we have not endeavoured to lay before him.

When a Plantation of one Kind does not ſucceed for this Purpoſe, it will be very proper that he try another; and when he is doubtful of the Kind that may be beſt, it will always be right to plant two. Moſt of the Hedge Shrubs that we have recommended, will grow as well two together as ſingly; and in this Caſe if one ſucceed, it will anſwer the Purpoſe; and if both, ſo much the better.

When there is Danger of a common Plantation not ſucceeding, from the Dryneſs and Barrenneſs of the Ground, it is always a good Caution to ſow Furze on the Side of the Bank. If the Hedge ſucceed perfectly well, this may be pulled up; but it rarely does ſo well but that a Bottom of this buſhy Plant may be an Advantage. The Winds that nip the Winter Corn in the Blade, get in more at the Hedge Bottoms than elſewhere; and nothing better than this fence againſt them.

Theſe are Accidents the Farmer is always to be aware of, and therefore the Preparation ſhould be made every where; and every Field will fare the better for it.

CHAP. XVII.

Of the Nature of Blights.

HAVING laid before the conſiderate Huſbandman ſuch an Explanation of the Effects of Changes in the Air, and of the Means of guarding againſt them, as we hope may ſerve in general Circumſtances for the Preſervation of his Cattle and his ſeveral Growths, we come now to conſider the particular Accidents to which each Kind are liable: and in the firſt Place thoſe which affect his Crops.

The firſt of theſe, as the moſt hurtful, is that which is very commonly known, but very little underſtood, the Blight. We ſpeak of it familiarly, becauſe it is common: but among the many Things that have been conjectured as to its Origin, very little ſaid has any Foundation in Fact.

It is a common Error in theſe Reſearches, to take thoſe Things for Cauſes which are only Effects: and nothing ſo much perplexes the Attempt to Knowledge.

As we have proceeded on other Occaſions we ſhall on this: we ſhall ſuppoſe, that in order to the remedying an Evil, the firſt Step ſhould be to underſtand its true Nature and real Cauſe; and this we ſhall endeavour to follow in the preſent Inſtance.

Among the Variety of Thoughts that have been delivered to the Publick on this Head, the Huſbandman, whoſe laudable and uſeful Curioſity ſhould lead him to ſearch after the Cauſe of this Diſaſter, would not know which to adopt: we ſhall curſorily name to him the principal of thoſe which have been received at different Times, and point out what Experience joins with Reaſon to determine.

The Blight is a Diſorder that affects Trees and Plants, and is as terrible to the Gardener as the Farmer. It appears in various Forms according to the Degree, affecting ſometimes entire Plants, and ſometimes only Parts of them. It is the ſame Diſorder which the Vulgar call a Blaſt.

When it ſtrikes a tender Plant, ſometimes the whole periſhes; and in ſome Caſes, the whole Border of a Garden, or the whole Produce of a Field, is loſt at once. At other Times it ſtrikes only a Part. The Leaves of Trees often fall off by this Means, while the reſt is unhurt; and ſometimes the ſame happens to Plants of leſſer Growth. Sometimes the whole Quantity of the Leaves are attacked, and ſometimes only a Part of them. The Leaves that are tainted by this Accident, ſhrivel up and appear ſcorched; and the Part of the Tree or Plant which is thus ſtruck with it is covered with little Inſects.

This Diſorder is common to almoſt all Plants, and to all Parts of the World: we read of Blights wherever we read of Gardening or Huſbandry; and for more than two thouſand Years Men of Ingenuity have been gueſſing variouſly at the Cauſe.

The Greeks, who, according to Theophrastus, called it Erysibe, looked on it as a Stroke from Heaven; utterly incurable and incapable of Prevention. The Romans called it Robigo; and as they deify'd Plagues and Fevers, worſhipping every thing they feared, like modern Indians, their fanciful Imaginations found a Deity upon this Occaſion; they called the new-made God Robigus; and Varro ſolemnly invokes his Bleſſing, that Blights be kept from Trees and Corn.

In general it was attributed to the Eaſt Winds; but Virgil, whoſe Huſbandry if it were better underſtood would be more followed, with much more Reaſon lays the Cauſe of it to Want of Care and right Culture; and, inſtead of praying to an imaginary God, adviſes the Farmer to betake himſelf to his Labour. It was not Want of Piety in this Poet, that referred him to the Uſe of Labour rather than fooliſh Rites. In this Caſe he orders the Farmer to pray for ſeaſonable Showers; and 'tis only the Worſhip

of an imaginary Deity, the Creature of Fear and Folly, he derides.

The early Notion of attributing Blights to East Winds, has been continued to this Time; and the Curious seeing Insects in such Abundance on the Leaves and Branches that have been struck, suppose these East Winds brought the Eggs of those Insects, and that they are the Cause of the Distemper.

Others have attributed the Cause of Blights to drizling Showers freezing upon the tender Buds, and that Way destroying them: in both these Conjectures there is some Foundation; but they err contemptibly who attribute this Disaster to the Aspect of the Planets. The Accounts however given by those who maintain the other Opinions are of little Consequence, for they agree with only one Part of the Subject. They attempt to explain only the Blights of the Spring, for both the sharp cold Easterly Winds, of which they complain, are most peculiar to that Season; and the freezing of drizling Rains upon the Buds can happen at no other. But there are Blights, and those terrible ones, at Seasons of the Year very different from these. Corn is often blighted in its full Growth, in a wet Summer. Therefore this Accident may happen without Frosts, or without those very sharp and cold East Winds, which though they frequently attend it, we perceive by this are not the Occasion of the Accident.

In the same Manner those Blights which are called Fire Blasts, and are the most terrible of all to a Hop Ground, happen in JULY oftener than at any other Time.

CHAP. XVIII.

Of the antient and modern Observations of Blights.

THIS shews that the Cause is not what these Persons have thought, and therefore that the Farmer must seek farther than their Advice for a Remedy. The same Accident that happens in this Manner in our Hop Plantations, us'd to damage the Vineyards of old ITALY. The Authors on Country Affairs, name it with great Marks of Concern, they distinguish it by the Name of Carbunculus, but this we find both by the Context and their own Account of the Disaster, was the same with the Robigo or Blight. Storms, PLINY says, were less terrible to the Vintage than this Blast, for they affected only particular Places; this cut off whole Plantations.

The Time of this terrible Damage happening to the Vineyards, appears to have been the very same with that in our Hop Grounds, and the Circumstances also the same. Ours happens toward the End of JULY, and theirs come on toward the ripening of their Grapes. What we read particularly of it is; that it generally followed violent, sudden, and short Showers, which happened about Noon in that hot Season, and were followed by clear Sunshine. They add, that it was sometimes partial, sometimes universal: that when it was partial, 'twas the Middle of all the Vineyards that suffered, and when it extended through the whole Ground, it always was plainly perceived to have begun in the inner Parts, and there to have been most severe.

This is the Account of a violent Blight in the Heat of Summer, in the Vineyards of ITALY, two thousand Years ago; and if we compare with this the exact and judicious Observations of Doctor HALES, made upon our ENGLISH Summer Blights in Hop Grounds, We shall see the antient * and the modern † very happily explain and illustrate one another: and the Farmer will thus, better than any other Way, be led toward the Discovery of the real Cause of the Disaster.

* *Columella de Re Rust.*
† *Hale's vegetable Staticks.*

No Plantation can so much resemble that of the antient Vineyard, as our modern KENTISH Hop Grounds: the Season for their Carbunculus is the same with that of our Fire Blasts, and the Circumstances attending both perfectly correspond. The Observations of our ENGLISH Philosopher are, that when there has been Rain, and a hot Gleam of Sunshine immediately followed it, the Fire Blast has happened: that it has attack'd the Plants in the Middle of the Hop Ground particularly, scorching them all up in a Manner from one End to the other.

The Damage in this Instance happened a little before Noon; and the Blight or Fire Blast ran in a Line at right Angles with the Sun Beams at that Time of the Day. There was little Wind; and that which did blow was in the Course of the Blight, or according to its Line. Those who would enquire into the Nature and Cause of these Disorders in Plants, are extreamly obliged to the Author of these punctual Observations; for comparing them with what we find in these old Authors, we find that the Nature of Blights is a fixed and certain Thing; that they appear in the same Manner, and observe the same Course, and that they plainly arise from the same Cause in the most remote Parts of the World.

This shews their Origin to be always, and every-where, from the same Principle; and it is not impossible upon so much Observation, to make a probable Conjecture what it is, and thence to attempt a regular Method of preventing its Damage or defending Plants and Trees from it.

This we shall endeavour to trace and direct in the most punctual Manner.

CHAP. XIX.

Of the real Cause and Origin of Blights.

BEFORE we enter on this Enquiry into the Cause of Blights, we must warn the Husbandman that he distinctly understand what is signified by that Name. We have mentioned the Circumstances and Manner of Appearance of Blights, and these, according to those Circumstances, we are about to account for; but we must remind him that many, for want of Consideration, confound together under this Name

almost

almoſt all the Diſorders to which Plants and Trees are liable.

A Blight, diſtinctly and properly ſo called, is a Damage ſuddenly happening to Trees and Plants, which appears in the Manner of burning, ſcorching, or ſhrivelling up the Leaves, and often withering the young Branches. This we have ſhewn happens ſometimes in Spring, ſometimes in Summer; and this is what is properly called by the preſent Name: if any call a Growth of whatever Kind blighted, becauſe it is ſtarved, or diſtinguiſh by that Name the Damage done by Froſts upon too early Bloſſoms, they are to be told theſe Diſorders of Plants and Trees come under the Heads of Accidents from Froſt, and Accidents from want of Nouriſhment, and will be treated of diſtinctly as ſuch. Therefore what is here mentioned under the Article Blight is a diſtinct Thing, and it is of the Cauſe of that alone we treat in this Chapter.

This Blight ſometimes affects a whole Plantation, or at leaſt the whole internal Part of it, and ſometimes only here and there a ſingle Plant. In the firſt Caſe, which is of the greateſt Conſequence, it depends in ſome Meaſure on the Nature of the Plantation, and therefore may be remedied or prevented; in the other it ariſes from Cauſes quite out of our Power, and we cannot do any thing to obviate the Miſchief; but it is of the leſs Importance, becauſe it affects but a ſmall Part of the Crop.

The Blight which we have deſcribed as affecting the inner Parts of Hop Plantations, and which the Antients mention as deſtroying their Vines, will alſo deſtroy whole Crops of various Kinds in the Field: we ſhall ſee the Cauſe of this, and therefore may reaſonably propoſe a Remedy.

As it affects the inner Parts of Plantations firſt and moſt, and as it follows Rain, there is all poſſible Reaſon to believe it is the Effect of a Vapour raiſed in Abundance in thoſe Places, and ſtagnating there; on which the Sunſhine operates to the Deſtruction of the Plants.

If this ſhall appear upon farther Enquiry to be the true Cauſe of Blights, the Remedy will follow plainly. It conſiſts in nothing more than keeping the Plantations clearer: ſetting the ſeveral Plants at greater Diſtances, and giving the Air free Way between them.

If the Outſides of the Hop Plantation eſcape, while the inner Parts are deſtroyed, what is the Cauſe of this, but that the free Air coming to the Outſides diſpels and ſcatters that Vapour, which ſtagnates in the cloſe Parts of the Ground, till the Sun, by its Means deſtroys the Plants. This plainly is the Caſe, and there is no other, nor can Reaſon propoſe, or will Experience vouch for any other Courſe. Therefore the Remedy will be to make the Plantations more open and free to the purifying Air. Moderation is to be uſed in this.

We know that Hop Grounds muſt be ſheltered from high Winds, or all will be deſtroyed; but at the ſame Time that they are ſheltered from the worſt Quarters, they may be left open on ſome others; though they are to be defended, they are not to be ſmothered up. This is the Effect of over Caution in weak Minds, but nothing is more dangerous. Let the Farmer in this Caſe, and all others, take Care that he avoid the common Miſtake of running into one Fault in ſhunning another; it is in this Caſe, as in many others, running into a worſe.

When the Ground is ſo diſpoſed that the Air can have free Ingreſs to all Parts of it, there will be nothing to fear from the Fire Blaſts of Summer. What is obſerved of the Hop Ground in this Caſe, holds good of all other Plantations: I only name that here becauſe this is the moſt particular, and in which it is moſt plainly ſhewn.

The Way to give the Air this free Ingreſs and Paſſage, is to place the Hills at greater Diſtances than uſual. We have laid down the beſt Diſtance in general Inſtances treating on Hops; but let the Farmer obſerve, that in Caſes where the whole Ground is more encloſed, the Paſſages within muſt be opener.

Too cloſe planting is moſt of all deſtructive to Hops, by bringing in theſe Blights, and Fire Blaſts, becauſe the Hop is ſo tall and large a Plant: but in all others it more or leſs affects them in this Caſe, according to their Height and Manner of Growth, and according to the Expoſure of their Situation.

The Summer Blights of Corn, and all other Crops, are owing to this ſame Cauſe, the Plants ſtanding too cloſe; in this Caſe the hot Sunſhine following large Showers, blights whole Fields.

The Caution to be given the Farmer is, that he plant all his Crops thinner than the uſual Cuſtom; and this we have recommended to him already, and have ſhewn him that his Produce will not be leſs, but greater for it. As this muſt be his general Caution, ſo in particular he muſt obſerve, that where the Place is moſt cloſe the Diſtance of the Plants muſt be the greateſt.

This Caution recommends the Horſehoeing Huſbandry as a Cure for Blights, and indeed there is none ſo certain or ſo great. Who ever ſaw a Field of any Crop treated in this Manner, blighted: 'tis not only the clearing the Ground between the Plants, that gives them this Advantage in the Horſehoeing Huaſbndry, but the affording them more Nouriſhment, that helps greatly. Starving and blighting are two diſtinct Things; but a ſtarved Plant will be ſooner blighted than one that is ſtrong and flouriſhing.

The Huſbandmen of old Time were aware of this; for Virgil preſcribes but one Remedy, which is Labour. Indeed this is one great Reaſon for our recommending the new Practice of planting at Diſtances, and breaking the Ground between for almoſt all Crops. The Plants are by this ſupplied with abundant Nouriſhment: no Weeds riſe to ſtarve them; and they cannot ſtarve one another; and the Seaſons and Elements are admitted to their Good, but can do them no Harm. The Showers are imbibed by this free and broken Earth between them, better than any other Way, and what is evaporated has the open Air to expatiate in, and goes off blended with it.

If we would be aſſured of the Truth of what is here advanced, reſpecting the Cauſe of Blights, our Eyes may be made Evidences. Let any Man look into a Hop Ground on a Sunſhining Day,

Day, after great Showers. In the Middle of the Ground, and every where when the Plants ſtand thick and cloſe, he will perceive theſe Vapours riſing in Abundance, and hanging with a quivering Motion among them like a light Smoak, where there is no Wind: if he look at the reſt of the Plantation, through them it appears dim and hazy; and if he look through them at a Church or Houſe, or other diſtant Object, his Eyes will ake by Reaſon of the confuſed Look and quivering Motion. Let him then examine whether there be theſe Vapours about the Outſides of the Ground, and he will find there are not. All is there clear, becauſe the Acceſs of the Air is free, and they blend among it as they riſe. The Blights and Fire Blaſts follow in the Middle and cloſe Parts of the Ground, and not on the Edges or among the outſide Plants. They come where theſe Vapours have been ſeen hanging; and no where elſe. There is this to cauſe them, and there is nothing elſe. Therefore in all Reaſon we muſt conclude theſe Vapours are the Cauſe, and no other.

We ſee the Occaſion, and the Remedy is eaſy. Let the Air have free Egreſs as well as Ingreſs among all Parts of the Crop, whether it be of a taller or lower Kind; and no Blights will be found. This is beſt obtained by following the Practice of the Horſehoeing Huſbandry, but any other Method of keeping the Plants at a Diſtance, and allowing the Air free Paſſage between them, will anſwer the Purpoſe.

Thoſe particular Blights which fall upon only a ſingle Plant in a Field, or any Part of a Plant or Tree, ariſe plainly from the ſame Cauſe with theſe general and terrible ones we have deſcribed already. Their Origin is an undiſſipated Vapour. If it be aſked, whether little Parcels of ſuch Vapours ever hang about in the Air, thoſe who are accuſtomed to the Uſe of Teleſcopes, can tell us that they do. 'Tis not eaſy to diſtinguiſh ſuch floating little Parcels of Vapour by the naked Eye, but when thoſe curious Perſons uſe theſe Glaſſes, they often ſee them come acroſs their View and diſturb the Sight.

One Thing that confirms the Opinion of theſe particular and partial Blights happening from ſuch little Parcels of Vapours is, that they generally come when there is little or no Wind. A greater Wind would break and diſperſe them.

This ſeems to be the true Account of their Nature and Origin, they, like all other real Blights, are owing to Vapours hanging in the Air, through which the Sun's Rays ſcorch the Plants, and this is not wonderful to thoſe who underſtand what muſt be their Power on ſuch Occaſions.

CHAP. XX.

Of Damages by Eaſterly Winds.

WE have ſhewn what is the real Blight, and what the proper Method of guarding againſt it, and preventing its great Damage; we are here to treat of all the Accidents to which Crops are liable, and ſhall therefore begin with ſuch as are called by this Name.

There are Spring Blights of the ſame Nature and the ſame Origin with thoſe of Summer, the Effect of ſcorching Vapours kept ſtagnating in the Air, and heated by the Sun. Theſe are to be prevented in the ſame Manner as the others, therefore nothing more need be ſaid of them here: but beſide theſe there are two Kinds of Damage done by Eaſterly Winds, and by late Froſts, which, though called by this Name; are in themſelves altogether diſtinct in Nature, theſe we ſhall conſider ſeparately in this Place. Eaſterly Winds in Spring often knip and deſtroy the tender Shoots of Plants of all Kinds, and they do this Miſchief by ſtopping the Current of the Juices in theſe young and tender Parts.

The Farmer ſees this, and ſo does the Gardener, for both are equally affected by it, but neither of them underſtand or indeed look into the Cauſe.

When the Juices are thus ſtop'd they ſwell the young Fibres, and the ſeveral Parts of the Leaves burſt and wither. The Juices guſh out in this Caſe, and they become the Food of numerous little Inſects. Wherever there is Food for theſe Creatures, Nature yields them in great Number to devour it; and conſequently in this Caſe there are preſently ſeen Abundance of them on the young decaying Shoots.

Theſe Inſects are always found upon theſe damaged Branches, and by a very natural Error they are ſuppoſed to occaſion the Miſchief. The Farmer imagines the Eaſt Wind brought their Eggs, and he ſtrews Tobacco Duſt over the Crop, or burns wet Straw on the Side of the Ground, from whence the Wind will carry the Smoak among the Creatures. In this he aims to deſtroy the Inſects, as if that would recover his Crop: but he errs from the Beginning. The firſt Step ſhould have been to guard againſt the Miſchief, and when that has been omitted every following Care is vain.

The Eaſt Wind does not bring theſe Inſects, nor are they the Occaſion of the Miſchief: they hatch where there is Food, the whole Air being full of the Eggs of ſuch Creatures, and they feed upon the Juices which theſe blaſting Winds have ſtopped in their Current. Theſe harmleſs Creatures do not eat the Leaves, or tear them; they find them burſt, and they feed upon what runs from their Wounds.

The Farmer may know when there is Danger from theſe Winds, their Effect is by abſolute drying and ſhrivelling up the Parts, and the Deſtruction they occaſion is ſolely brought on that Way. We know the Effect a drying Wind will have upon any tender Leaf expoſed to it, when taken from the Tree or Plant: theſe young Shoots are thus tender while they are upon the Branches, and the Effect is the ſame. The Wind ſhrivels them up. When there are moderate Showers now and then, or when there are but good Morning Dews, theſe Eaſtern Blaſts do no Harm. The only Seaſons when they are deſtructive is ſuch as are perfectly dry. Therefore the Farmer knows when he is to fear the Damage.

When he ſees a dry Spring, and the Wind ſet in Eaſterly, let him go over his Fields and his Orchard, and ſee what Part of his Crops are

forwardeſt, for they will be in moſt Danger. Let him not ſtay for the Appearance of Inſects, but prevent if poſſible the Effect of the Blaſts: and this is to be done by proper Defence and Shelter. The Uſe of thick Furze Buſhes may ſerve excellently for this Purpoſe; and they ſhould be ſtuck in the Ground in cloſe Rows, not only on the Side of the Field where this deſtructive Wind is likely to come in, but in different Places, at ſome Diſtance in the ſame Direction.

We ſee the Cauſe here is ſo different from that of a common Blight, that the Remedy is to be juſt of the oppoſite Kind: in that Caſe the Wind is to be admitted among the Plants by all Means; becauſe it will carry off thoſe Vapours which are the Occaſion of the Miſchief: and in this it is to be kept off as much as poſſible; becauſe it is itſelf the Cauſe of the Injury.

This may ſerve as an Inſtance of the Neceſſity there is of the Farmer's underſtanding the Cauſes and Nature of all thoſe Accidents that may befall his Crops. We ſee in the preſent Caſe, that by the improper confounding of two Things of contrary Cauſe and Nature, under the ſame Name of Blight, he might be led to practiſe that for a Remedy, which would be the very Cauſe of promoting and extending the Damage.

We have now inſtructed the Farmer to diſtinguiſh the Cauſe from the Effect; and having taken the proper Precautions in this Reſpect, we may lead him to conſider the other. When he has ſheltered a Crop that may be in Danger on this Occaſion, let him from time to time examine whether his Precaution have proved effectual. If in any Place he ſees his Plants hurt while they are free from Damage in others, let him thicken the Shelter againſt that Place, and then, having provided againſt the extending of the Damage from the original Cauſe, let him take care that it be not encreaſed by its natural Conſequences.

We have ſhewn the Inſects which appear on Plants nipped by eaſterly Winds, are not the Cauſe of that ſhrivelling and withering of their Parts; but they may very much contribute to the ſpreading of the Diſorder. Wherever they are firſt hatched they breed extreamly faſt; and that in a very particular Manner. They do not wait the ordinary Method of Copulation of both Sexes, but they are all Breeders: and the Young produced from them are full of others, which they diſcharge from time to time, and ſo on at leaſt for ſeveral Generations. This may appear ſtrange to many, and it is one of thoſe wonderful Proceſſes of Nature, in which for particular Purpoſes ſhe departs from her uſual Tract and Courſe. Mr. De Reaumur, of the Royal Academy of Sciences at Paris, the Ray or Sloane of France, had the Curioſity firſt to diſcover and trace this wonderful Procedure, and many have ſince obſerved it: any one may, for the Creatures are common enough; and if one of them, any one at random, be put into a little Box and kept alive, it will produce its Young; and any one of theſe Young taken out as ſoon as born, and kept in a ſeparate Box, will do the ſame; and its Young after it. The Experiment has been continued through five Generations. This may ſhew us how abundantly the Inſects on a nipp'd and injured Plant will encreaſe; and they will ſpread the Miſchief by wounding other Parts of it. An accidental Injury brings them to the Plant, but they are capable of doing a great deal themſelves. Having fed upon the Juices that iſſue out of the burſt Veſſels of the Leaves, they will pierce them in other Parts in Search of more: and thus the Plant will be full of Wounds. Out of all theſe the Juices will flow, and they will thicken and grow clammy in the Air: and this being the proper Food of theſe Creatures; not only their own numerous Brood will from time to time encreaſe the Miſchief, but this Quantity of new Food will occaſion the repeated hatching of more and more of the ſame Kind, brought in the Egg or Embrio as the firſt were in the Air.

For theſe Reaſons, when the Huſbandman has found what Part of his Crop has ſuffered by the dry Eaſt Winds, and has guarded againſt their farther Damage by improving the Shelter in that Place, let him ſet to work to prevent the ſpreading of the Miſchief already done by deſtroying the Inſects, and by ſpoiling their natural Food.

This is not to be done by ſprinkling Tobacco Duſt, or any ſuch Method; for that will only damage ſuch of the Juices as are already out, and the Conſequence will be, that the Creatures will neglect thoſe Parcels and wound the Plant in new Places for more. This ſhews that the natural Conſequence of uſing this Duſt by Way of Remedy, is the encreaſing the Diſorder; and ſo I have found it by Experience.

We have obſerved that dry Winds occaſion this Miſchief, and it is dry Weather that ſupports the Inſects which appear upon the hurt Plants. Of all the Methods that can be deviſed for their Deſtruction, none will be found ſo effectual as the drowning of them. The Plants ſhould be well watered every Day with a watering Pot, and this repeated conſtantly till natural Rains fall. It will, if not utterly and entirely remedy the Evil, yet certainly abate, perhaps totally ſtop its Progreſs.

We ſee conſtantly that Rains deſtroy theſe Creatures, and reſtore ſuch Parts of the Plants as are not utterly deſtroyed to their former Vigour.

Nothing can be ſo reaſonable, ſo prudent, or ſo proper, as to imitate this Relief of Nature by Art, and nothing will have ſo good Effect. This watering of the Plants will not only deſtroy many of the Inſects, but it will waſh off the ſweet Juice that hung on the Leaves, and would have brought more: and at the ſame Time that it is anſwering theſe excellent Purpoſes, it will be obviating the very Cauſe of any farther Injury from theſe Winds, by remedying the Dryneſs of the Seaſon.

The Plants ſuffer in their Shoots by theſe Winds, becauſe there is no Moiſture to prevent their ſhriveling up by them: and by this Means that Moiſture, ſo needful to the Ground, is given by the Hand of the Huſbandman, though it be with-held in the Clouds. The watering them all over anſwers this Purpoſe extremely for the Time when it is doing; but the good Effect is not limited to ſo ſhort a Continuance. The

Vapours riſing from the wetted Ground ſoften the Air, and the young Shoots and Leaves are kept in ſuch a Condition of Moiſture, as to reſiſt the Effect of parching Winds all the ſucceeding Day. Let our Farmer on this as on all other Occaſions be upon his Guard, that he do not, by an ill managed Application of the Remedy, hurt more than the Diſeaſe would have done. Let him remember, that watering in an Evening when the Nights may be froſty, as they frequently are at this Seaſon, may be the entire Deſtruction of his Crop. He muſt for this Reaſon be ſure to water and waſh his Plants only in a Morning, and he need not fear damaging them then; for the Dryneſs of the Seaſon will make this uſeful in every Reſpect. The whole Day coming after the watering, ſome will be taken in by the Plant, ſome evaporated; and the Quantity that remains in the Ground at Evening will not be enough to do the Plants any Damage by the Night's Froſt.

Thus many good Purpoſes will be anſwered at once by the Method we have directed; and it will not be impoſſible but that the damaged Part thus managed, may prove the very beſt Piece of the Ground.

CHAP. XXI.

Of Damages by late Froſts.

WE have ſhewn that one of the Accidents which happen in early Spring to the Crops of the Field and Garden, and which is improperly called a Blight, may be remedied by due Care: we come here to treat of another Damage of the ſame Seaſon, called in a confuſed Manner by the ſame Name, but altogether different in Nature. The unexperienced Eye is pleaſed to ſee the early Appearances of Spring in the Garden and in the Field; but the more judicious tremble for both. In our uncertain Climate, nothing is more ſubject to Deſtruction than an early Shoot: we have Froſts frequently very late in the Spring, and theſe nip and deſtroy all ſuch early Shoots. It is therefore our Happineſs, when the Seaſons are more regularly ſeparated from one another; when the Winter takes its Time, and the Spring begins late enough to continue uninterrupted.

When it has happened that a Crop of tenderer Kinds has ſhot briſkly from ſome early ſoft Weather, the ſevere Morning that follows nips the tender Leaves and they fall off, and not unfrequently the young Shoots with them: this is a Stoppage in the Growth that retards it vaſtly, and that is very difficultly recovered.

We ſee the Occaſion of this Damage, and the Conſequences; but nothing is ſo difficult as to propoſe a Remedy for it.

The Gardeners, whoſe Bloſſoms and young ſet Fruit are frequently injured by this Accident, have Recourſe to a Method of Prevention which encreaſes the Diſeaſe. They cover up the Trees with Mats, and thus indeed defend them from the preſent Froſts; but they make the Shoots by this Means ſo weak, that they are ſure to be deſtroyed by the next. If the Farmer could any Way imitate this Practice, it would be by ſcattering Straw or Haulm over ſome tender young Crop: but in this Caſe, without the utmoſt Care, more Damage would be done than Good. If he ever ſhould be tempted to follow this Practice, there is but one Way of doing it ſafely, and that is attended with a great deal of Trouble: he muſt have this Covering of his Plants ſcattered ſlightly on every Night, and removed every Morning; raking it together in ſeparate Heaps, from whence it muſt be thrown upon the Crop again in the Evening. If it were ſuffered to lie on all the Day, the Plants would be drawn up ſo weak, that like the Shoots of the Trees in the Garden, they would be ſure to be deſtroyed by the next Froſts.

Though we can fence off Winds, and waſh away Inſects, we cannot command the Temperature of the Air; nor is there any Way of defending our young Growths from it other than what is juſt named: but we have on all Occaſions warned our Huſbandman to be wiſe betimes; and in this Caſe more than in moſt others it is neceſſary.

Let him before he commits his Crop of whatever Kind to the Ground, conſider the Dangers to which it will be expoſed; the Methods that he ſhall have in his Power for guarding againſt them; and the Chance of the Advantage from early Growth; and of their Deſtruction or Eſcape. 'Tis thus he will be able to judge, and no otherwiſe, of what is the proper Method of acting.

Some of his Crops are required early, and to others it is of little Advantage: this we have before explained under the particular Articles; and let him well conſider it in this Caſe. The earlier he ſows, the earlier his Crop will riſe; and the ſooner in Spring it is up, the more it will be expoſed to this Danger. Let him run the Hazard; for none but ſuch as will, have a proportioned Benefit from their Forwardneſs: and with reſpect even of theſe, let him be moderate; for it is not being out of the Ground at an extreamly early Period that is ſo advantageous. The great Benefit ariſes from ſo contriving the Crops, that they will be in a Condition of Growth upon the earlieſt Setting in of proper Weather. This he can only know by Gueſs: but having formed the beſt Conjecture he can, let him ſow accordingly; and if when the Crop is up the Froſts threaten, let him defend it in the Manner we have juſt mentioned.

CHAP. XXII.

Of Damages from Weakneſs and Starving.

WE have obſerved that among the many Diſorders of Plants, comprehended under the Article of Blights, in the common Way of ſpeaking, one was that of Weakneſs in the Growth from ſome Accident, which ſtarved it.

The very ſame Effect which we ſee produced by a real Blight, we ſometimes alſo find attending this Accident; and the Account for it is very

very eaſy. In that Caſe a thick Vapour, by Means of a ſtrong Sun, has ſhrivelled the Leaves, and ſcorched the tender Stalks of a Plant: and in this a like Accident happens from the Want of Nouriſhment. Thoſe Parts neareſt the Root are beſt ſupplied with Juices, and therefore they are full, flouriſhing, and fine; while ſuch as are fartheſt off from that Source of Nouriſhment, wither when there is not enough to feed all alike.

'Tis the ſame in this Caſe as in the Human Body: when the Heart cannot drive the Blood through all Parts; thoſe fartheſt from it ſuffer firſt, the Hands and Feet have the Juices firſt ſtagnate in them; and in the ſame Courſe in the Plant the Tips of the Branches, and thoſe other Parts moſt remote from the Root are firſt affected in the Caſe of ſtarving.

We name this for the Farmer's ſtrict Obſervation; becauſe it will let him into the Nature of the Diſorder, without which it is impoſſible for him to find the proper Remedy. When he examines what is called a blighted Crop, let him look carefully to this: no Matter that Inſects crowd, and Leaves curl up; and that all the Signs of real blighting appear: if he perceives all the Tips of the Stalks and Branches affected; and few other Parts, he may be ſure the Diſorder is no Blight or Blaſt, but a Stagnation of the Juices in the Tips or Extremities of the Plant, for want of a freſh Supply to force them on in their natural Courſe.

Although there is not a Circulation of the Juices in Plants, as ſome have ſuppoſed, there is a continual Motion forward to the Ends of the Branches, where a great deal is diſcharged by Perſpiration: this we have ſhewn in a former Part of the Work. This Motion of the Juices is altogether neceſſary to the healthful State of the Plant; and whenever it ceaſes the Part in which it is kept becomes diſeaſed.

Knowing thus much of the Oeconomy of Nature, in the Management of Plants, we ſhall not find it ſtrange that this Stagnation of their Juices happens from ſtarving. When the whole is in a flouriſhing State, the Root takes in a great deal of Moiſture, which it ſends upward in a conſtant Motion, and this drives on the reſt. When there is not enough of this received, and the Plant is not vigorous enough to throw it upwards, this Motion grows faint. The Juices ſtagnate and ſtand ſtill in the extream Branches: and where they ſtagnate they always burſt the Veſſels by the Sun's Heat, and ſweat out.

This is the Signal of Nature to all the Inſect Tribe together. Their Eggs or Embrios are floating every-where in the Air; and wherever there is Food for them they ſtick and hatch into Life; and they breed abundantly. Theſe come therefore wherever there are corrupted Juices in Plants; and their Appearance is as natural from ſtarving as from ſcorching of the Plants: from this it has happened that both Accidents are called by the ſame Name by the Vulgar; but let the Huſbandman learn the Difference, becauſe they require altogether diſtinct Remedies.

When the Cauſe is ſeen to be a Defect of Nouriſhment, and not a ſcorching Vapour, the Remedy is natural, but it is not equally eaſy to be applied in all Caſes. The Farmer will here ſee another Inſtance of the Excellence of the Horſehoeing Huſbandry. This Sort of Blight, as it is called, may always be remedied preſently in that Method, becauſe it is in our Power at any Time to give the Plants a due Supply.

What cannot be done ſo well in the common Method, yet muſt be attempted in the beſt Manner in the Farmer's Power upon the ſame Principle.

It will rarely happen that a Crop raiſed in the new Huſbandry is ſubject to this Diſorder, but when it is the Remedy is to ſend in the Hoe Plow, and tear up the Ground to a good Depth between the Rows. This giving the Plant abundant new Nouriſhment, as we have ſhewn, the Diſeaſe is remedied at once. The whole Crop ſhoots ſtrongly; and the little Inſects, whoſe Food depends upon the ſtarved Condition of the Plant, drop and die off of themſelves.

This is the ſhort End of a ſtarved Condition from Neglect in the Horſehoeing Huſbandry, for be the Soil what it will, ſtarving can only be the Reſult of Neglect in that Method. The Earth being broken ſmall is ready to receive the Dews and Rains, which will waſh its new brought Nouriſhment into the Roots; and the Roots will be ſent out in vaſt Multitudes to receive it; for the Conſequence of this plowing near them is, that their Roots are all cut off at the Ends, as thoſe of a Plant new ſet by a Gardener, and they ſhoot out innumerable others in Conſequence. This we have ſhewn before to be the Fact, in numerous Inſtances, and remind the Farmer of it in this Place, that he may underſtand how perfect a Remedy is this Way in his Power.

When a Crop of ſome of the large growing Plants, for they are moſt ſubject to this Accident, are thus endangered by ſtarving in the common Courſe of Huſbandry; the Hand Hoe is all that can give them Aſſiſtance, and it muſt be immediately employed. There is in this Caſe no clear Interval for cutting deep into the Ground, but what Space there is between Plant and Plant, muſt be clip'd as well as it can at the Edges and Surface. This will have ſome Effect; and indeed, if wiſely and boldly employed, may have more than the Farmer will at firſt expect.

What has aſſiſted to the ſtarving of the Crop in this Caſe is, probably either a large Growth of Weeds among the Plants, or their ſtanding too cloſe to one another.

In the firſt Caſe this Hand Hoeing is a Remedy, becauſe all the Weeds of what Kind ſoever, will be cut up by it; at the ſame Time that it breaks the Ground between the Plants, and cuts ſome of their ſuperficial Roots. But let the Farmer not ſtop here, in this Caſe of ſtarving, moſt probably the Plants ſtanding too cloſe has been the Occaſion of it; or if not no Way is ſo ſure to recover one half, as to cut up the other. This will give the Hoers Leave to work more boldly, and give more Scope to their Strokes, that they can cut deeper: the Earth will be more broken, and the Air, Dews, and Rains better let in: the Wind will be able to blow freſh between the Plants alſo, and every thing will thus tend to their Recovery.

Let

Let not the Husbandman grudge the Part of his Crop that is to be destroyed. DARIUS did well to offer half his Kingdom; and it would have been happy for him if ALEXANDER would have accepted it, and left him the Remainder. In this Case the Question is not whether the Farmer shall have half or all; but whether he shall have half or nothing. I have thus seen a Field of Coleseed saved to the Owner in NORTHAMPTONSHIRE, when every body gave it up for lost; and I really believe it yielded him more Seed from the half, or less than half the Plants that remained, than it would have done from the whole, if they had gone on ever so well in his crowded Method of planting them. In this Case, as in some others that I have seen, I am strongly of Opinion, that a great Part of the Mischief happened from the sowing so thick, that the Plants choaked and starved one another: and it is certain, that there is no Remedy like thinning them to a proper Distance. When the Husbandman shall see the young Plantation we have directed for his Orchard decaying in the same Way, let him pursue the same Method of Relief as we have directed in Case of Crops, by the Horse-hoeing Method.

In the common Plantations he must dig round the Trees with a Spade, breaking the Earth well, and throwing it in carefully and lightly: but in our Method of planting distant for cultivating the Land between, let him bring in the Plough, let him bear very near the Roots of every Tree that is in this sickly Way, press the Plough deep, and make the Share, as VIRGIL says, shine from the Furrow. This will give new Nourishment and new Life to the Plantation; and thus in every other Article, where the Mischief plainly happens from a starv'd Condition, let him give the Crop a more abundant Nourishment, and make it shoot strongly. This done, he need not trouble himself about the Insects; for, as the Doctors say, when the Cause is taken away, the Effect ceases.

CHAP. XXIII.

Of the Nature of Mildew.

THE Farmers are imposed on in nothing more than the Names, Nature, and Causes of the several Accidents to which their Crops are liable: and while they are not rightly informed in this Respect, they can never attempt any thing rational for their Cure. They hear certain Words continually repeated as the Names of various Accidents; but those who speak, and those who write, confound them one with another: we shall shew them distinctly what each Name means; what each Disorder is; and what Remedies are in their Power. Nothing is more needful to the Husbandman than this Knowledge, and nothing is more wanting.

Some have asserted, that Blights and Mildew are the same Thing; but these err, for they neither are the same in their Nature or Consequences: neither are the same Remedies or Precautions proper; therefore this is a very hurtful Error.

Others differing from these too widely, in the Vehemence of exposing their Error fall into another of as bad Consequence. They say they are not at all alike in Cause, or in their Nature. This is palpably a great Mistake; for they are alike in some Respects, though they are not the same.

We shall endeavour to set the Husbandman right in this important Article; and in order to it shall refer him to what he sees in Nature, not what he may have hitherto read in Books. Indeed the first Step toward his arriving at the Truth, must be his understanding the Errors which have been delivered to him as the real Accounts of the Accident.

Nothing can set the common Class of Writers on this Subject in a meaner Light, than the observing in the present Instance how they have transcribed Mistakes, and copied unmeaning Words from one another.

Old MARKHAM fetches Mildews from the Heavens. He attributes them to baleful Influences, and malignant Vapours of the Sky; which striking to the Earth alter its sweet and pleasant Nourishment, and change it into Bitterness and Rottenness; whereby the Corn is slain outright, or rendered withered, lean, and all unkindly *.

This Doctrine passed for current, till the succeeding Days of WORLIDGE, who searching nearer Home for the Disorders of his Crops, attributes this to a fat and moist Exhalation from the Flowers, and other Parts of the Vegetables, condensed by Cold in the upper Region of the Air, and thence falling upon Plants again †.

The Language of MARKHAM is florid in his uncouth Way; and that of WORLIDGE is familiar enough. In general, the farther People in these Studies deviate from plain Language, the farther they depart from Utility: these are Writings meant to inform the Mind, not to please the Imagination. The Fields may laugh and sing in Prophecy, and VIRGIL may have Beauty in his *intereunt segetes* §, for his Georgicks are Poetry: but these are not the Expressions which should be used in laying down the practical Rules to the industrious Husbandman, and explaining their Uses.

WORLIDGE has delivered his plain, original Conjecture, and many have adopted it; for MARKHAM's was the Error of his particular Age, and could not be well received in any other.

Industrious MORTIMER has copied honest WORLIDGE, not his Thought only, but his Words ‖; not so much as attempting to reason or improve upon him. WORLIDGE, though not exactly right himself, yet laid a Foundation on which a little plain Sense and good Observation would have arrived at the whole Truth.

From MORTIMER, CHOMEL translating this imperfect Account, * conferr'd a lasting Obligation (such were the Words) upon his Country; and from CHOMEL 'twas englished back again, under the Auspices of BRADLEY †.

Thus we see how many write, and how few think: how Error goes the Round of different Nations: that which was old in BRITAIN, after it had appeared new in FRANCE, grew new again

again at home, in the Tranſlation of that firſt Tranſlation. From theſe, unaltered, unimproved, and unamended, the Account made its Way into the Compilations of Chambers ‡ and of Miller ‖; and from them into the patched Productions of ſtill later Writers below Contempt.

‡ *Encyclopædia.* ‖ *Gardener's Dict. Article Mildew.*

This is what the Farmer meets with, if he have Curioſity to read for Information. This was the State of uſeful Knowledge in a Country famed for its Improvements during almoſt a Century. The firſt rational Advance he is to make toward Truth, is, by ſeeing the Errors and the Imperfections of theſe Accounts; and the next is, to read it in the Book of Nature.

CHAP. XXIV.

Of the real Cauſe of Mildew.

WE have ſhewn the Huſbandman that the firſt Accounts of Mildew were erroneous, and that the later have been all imperfect. It is not true that Mildews are ſent down from the Clouds; nor can they ever be underſtood by thoſe who join the Exhalations of the Earth and thoſe of Plants together for their Cauſe. Let the Farmer look out into his Fields, and when he ſees a ſettled Mildew on his Crop, he will find Inſects, juſt as in the Caſe of Blights, feeding upon a Honey-like Moiſture lodged on the Plants; and where it is but beginning, he will find this Moiſture tho' leſs thick, yet ſweet and clammy, covering the young Shoots, tho' the Inſects have not found it.

This ſhews him, that the Cauſe of Mildew is the hanging of a thick ſweet Moiſture on the Plants; here is his firſt Step to the true Knowledge of the Diſorder; the next is to enquire whence this Liquor comes, not from the Clouds or Skies, according to Markham; for only pure and ſimple Water can get thither, nor did any thing elſe ever deſcend from thence: neither can ſuch a Juice riſe from the Earth, as Worlidge fancies, for there is none ſuch there. Waters may be impregnated with Minerals, and their Virtues may riſe with them; but there can be nothing of the Honey-kind raiſed from thence. The Earth can ſend up nothing but what it has, let the Sun's Power be what it will; and it has not in it the ſweet Juice which occaſions this Accident.

To underſtand this rightly, let the Huſbandman perfectly inform himſelf what this ſweet Liquor is; it is but one Thing in whatſoever Form it appears. Whether it be ſolid or liquid it is the ſame Subſtance; and whether we ſee it in the Form of Honey from the Bees Stores, of Manna from the Aſh Trees, or of Sugar from the Reed.

We ſee there is ſuch a Subſtance in Nature, and but one ſuch; and, to underſtand this Diſorder which it cauſes, let us enquire whence it comes. It is not dropp'd down from the Heavens, nor drawn up by the Sun from the Ground; this we have ſhewn: there remains but one way it ſhould come, and therefore that muſt be the true Source of it. Since it is not originally in the Earth or Air, it muſt be produced in the Bodies of Plants; and that is its true Origin.

The Juices of the Earth are received into the Roots of Plants; and theſe, as we have ſhewn in a preceding Part of this Work, are only Water and the fine Part of Mould, and of Manure: Water alone will, to many Plants, anſwer the Purpoſe.

Of whatever Kind they be in any particular Inſtance, whether Water alone, or Water and pure Earth; or, laſtly, Water, Earth, and the fine Part of Manure, they have nothing of this ſweet Taſte, nor of the Honey or Sugar Nature. They are received into the Veſſels of the Plant, and there, by an Operation to be admired, not to be underſtood, they are converted partly into the ſolid Parts of the Herb, and partly into theſe ſweet Juices.

We know this is done, becauſe taſting theſe Subſtances firſt we find they are not of this Nature; and examining the Juice of the Plant afterwards, we find that is ſuch; but we cannot enter into the Secrets of Nature ſo far as to find how it is done. Let the Farmer, more humble than the Philoſopher, be ſenſible of this, and know where to ſtop his Enquiries. It is enough for all uſeful Purpoſes, that he knows this Juice is there, no Matter how it comes. This ſweet Juice of Plants is extracted by the Bees from their Flowers, in its own proper Form, and lodg'd in their Combs as Honey. From the Sugar-Cane, the Juice being boiled down, leaves it in Form of Sugar; nor is that peculiar to this one Plant: the Juice of the Maple-kind is, in ſome Parts, boiled to Sugar, in the ſame Manner; and that of the Birch, or any other Tree, or Plant, properly managed, may.

This Juice, which is thus ſeparated in the Flowers, or lodged in the Sap, may ſhew itſelf on the Outſides of the Leaves and Branches. It does this on the Oak in our Country, and is there called Honey-Dew; and in Italy, particularly in Calabria, it does the ſame on the Leaves and Branches of the Aſh, and is called Manna. This is the Circumſtance that comes neareſt to our preſent Purpoſe. In the Courſe of Nature this ſweet Liquor ſhould be kept among the Sap, except the little that is ſeparated in the Glands of Flowers; but we ſee that in theſe two Inſtances it will ſhew itſelf in a ſeparate Form on the Leaves.

It is not the Oak alone in our Kingdom that has this Honey-Dew upon its Leaves; nor is the Aſh the only kind that has it, in hotter Countries, in the ſhape of Manna. The Manna of Briancon in France, is gathered from the Larch Tree, and that of Persia from the Alhagi, yet theſe are both true and genuine Manna.

This Juice, which is thus contained in all Plants, may by Accident be brought out to the Surface, and being there diſlodged, it will ſhew itſelf firſt in a clammy Moiſture; and afterwards, according to the various Circumſtances, in a tough Matter like Honey, or in a dry and firm Subſtance, as Manna. Experiments have been made to prove that the French Manna did not come from the Clouds, but was the real ſweet Juice of the Plant, which perfectly ſettle this Queſtion. Boughs have been cut off clean

in the Manna-Seaſon, and the Manna has been found upon them ſome time after, tho' they had lain within Doors.

This, and many other Obſervations of a like Kind, ſhew that the ſweet thick Subſtance found on Plants, is not rais'd from the Earth, or dropp'd from the Sky, but is ſweated out by the Plant itſelf.

Trees can bear this better than tenderer Herbs, and to this is owing the Difference of its Effects, in not hurting the one Kind, and injuring greatly the other.

This ſweet Juice is the Cauſe of Mildew; and the Farmer knowing its Nature and Origin, will rationally be led to enquire into the Manner of its doing the Damage, and thence to the proper Remedies.

CHAP. XXV.

Of the Accidents which bring on Mildews.

THE Reader will ſee from this plain Account of the Cauſe of Mildew, what is the Difference between that and the Blight: we have ſhewn that it is occaſioned by a Condenſation of the Juice of the Plant within, and this from a Sweating of it out. 'Tis ſeen, therefore, that though not the ſame Diſorder, they are allied in their Nature; but as their Cauſes are different, ſo are their Methods of Cure.

The Cauſe of Blights is often a cold Wind; but the Occaſion of Mildew is frequently a hot Sun, and a perfectly ſtill Seaſon. This agrees very well with the rational Account of the Nature of theſe Accidents; for Cold is moſt likely to coagulate the Juices in the Veſſels, and Heat to draw them out of them.

The pooreſt and even weakeſt Trees and Plants are moſt ſubject to Blights, becauſe in them there is the leaſt Force of Nature to carry on the Motion of their Juices againſt the Effect of Cold; but, on the contrary, the richeſt and ſtrongeſt Plants are moſt ſubject to Mildew, becauſe they bear the richeſt and the moſt abundant Juices. From theſe Obſervations, conducted by a firſt eſtabliſhed Knowledge of the Principle and Cauſe of the Diſaſter, we ſee the Errors of the Conjectures made by others, and the unhappy Effects they have taken upon their Practice.

Where moſt Manure and moſt Tillage are uſed, the Plants will be richeſt: and where, with equal Tillage, there is more Manure, thoſe Plants will, in the natural Degree, be richer than where there is leſs. On this is founded the Obſervation, that where there has been moſt Dung uſed, the Crop is moſt ſubject to Mildew. But thoſe who have credited the Accounts heretofore given of this Accident, being occaſioned by Vapours from the Earth, have been led into a very erroneous Imagination by it: they have thought that the Vapours of the Dung cauſed the Mildew; whereas that Manure had indeed done nothing but its proper Office, and the Crop had fallen under this Misfortune from the great Richneſs the Plants received from it. Upon this Principle the Farmer will ſee that a good Quantity of Manure will defend a Crop from Blights; and tho' it makes the Plants more liable to Mildew, that may be guarded againſt by other Meaſures.

Let the Huſbandman keep in his Mind the diſtinct Nature of the Blight and Mildew, for this Reaſon: he ſees they require a different kind of Caution; and in ſtarving his Crop to prevent the one, he may run it into the Danger of the other.

There is at all Times a great Quantity of Moiſture exhaled from Trees and Plants, and the abundant Diſcharge of this, when there is not a due Supply, may occaſion both the Accidents of Blights and Mildew; the firſt in the Spring, the other in Summer. It is the Opinion of Dr. HALES, that when the Moiſture is exhaled from Trees, in a cold Spring, faſter than it is ſupplied from the Root, this occaſions that Blight in which we ſee the Bloſſoms and Leaves of Trees fall in Spring *: and, on the other Hand, when in the Heats of Summer the Quantity exhaled is vaſtly great, and the Plant is rich in theſe ſweet Juices, they may be exhaled when there is not a ſufficient Supply of the others; and this the more, the greater the Heat is, and the richer the Ground has been made by Manure.

* *Vegetable Statics*. Vol. I. p. 368.

This is an Accident in the Courſe of Nature, which often happens without any Damage following it; but when the Weather is leſs favourable there is great Miſchief: this being the real Cauſe of Mildew.

In the Heat of the Day this ſweet Juice comes out; and while the Heat continues it is not much perceived. It muſt have been rendered thin, in order to its getting out of the Veſſels; and the Heat which effected that Change in it, keeps it in the ſame Condition, during the Time the Sun is above the Horizon.

At Sun-ſet this Juice would thicken from the cooler Temperature of the Air; but then the Dews cover the Surface of the Plant with Water; this blends with the thick Juice which lies on the Leaves, and waſhes it away.

Whatever has been once diſſolved in a watery Liquor, will readily diſſolve in it again; and as this thick ſweet Matter was originally mixed with the watery Juices in the Veſſels of the Plant, it naturally and readily will mix with the Dew, which is alſo watery. This is Philoſophy, and this is Truth: the plaineſt Words beſt convey Knowledge.

The Farmer ſees the natural and proper Courſe of Things, and in this there is no Accident. No Mildew is ſeen upon the Plant, tho' the Honey-Juice has been exſudated, becauſe it has been waſhed off again before it had Time to do Miſchief.

If it had lain longer, it would have ſpread itſelf over the Surface of the Plant, ſtopped up its Pores, and ſpoiled its Growth; and it would have invited Inſects to feed upon it, which would have ſpread the Miſchief farther, as we have ſeen in Blights.

When the thick Juice is thus quickly waſhed off the Plant, no Harm happens; when it lies longer, the Mildew follows; this is the Courſe of the Accident.

There are Nights in which there is very lit-

tle

tle Dew; and, in this Caſe, as the thick Juice will remain on the Leaves, there is the Foundation laid for the Diſorder: but there are yet many Chances for the Crop's eſcaping. If a Shower of Rain falls the next Day, it will waſh away all, and there can be no Miſchief to the Plants: if this do not happen, there is the Chance of another Night of Dew, and this will ſtill take Place. Even a third Night's Help from Dew, after two dry ones, will anſwer the Purpoſe if there be a briſk Wind in the Morning; but if otherwiſe there commonly comes on the Damage.

A Wind at any Time, whether after Rain or after Dew, is of the greateſt Service againſt this Diſorder; and it is for this Reaſon Corn, in open Fields, eſcapes this Danger more than in Encloſures.

Every Article of Improvement has its Diſadvantages, which muſt be guarded againſt, otherwiſe they may counterbalance the Benefit. Thus in the preſent Inſtance, the encloſing Land, and enriching it with Manure, both make the Crop the more liable to this Accident of Mildew, but they defend it from many others, and encreaſe the Product ſevenfold. Therefore the Buſineſs of the Huſbandman is to guard againſt the Damage attending theſe Improvements, while he reaps their Benefit.

He will now underſtand perfectly the two fundamental Points, 1. What is the Cauſe of Mildew; and 2. What are the Accidents that bring it on. He will therefore have a rational Foundation for his Practice in guarding againſt the Diſorder, and in endeavouring to remedy it when it ſhall fall upon his Crops in ſpite of all his Caution.

CHAP. XXVI.

Of the Prevention of Mildew.

WHEN the Huſbandman's Land is rich, and his Crop ſtrong, let him be upon his Guard to perceive this Accident if it happen, that it may not be gone too far before he attempt a Remedy.

Let him provide againſt it by making his Encloſures larger for Corn Land than for Paſture; and by leaving Openings at certain Diſtances, at the Height of about five Foot.

This is a new Practice we are ſenſible, but it is of the greateſt Importance. It may prevent half the Miſchiefs that happen to Crops in encloſed Ground.

We have ſhewn, in ſpeaking of Blights, the great Neceſſity there is of the Air having a free Paſſage among Plants of every Kind; and this is always more or leſs obſtructed by Encloſures. The Winds that hurt a young Crop come in only from certain Quarters, theſe therefore may be defended thicker than the others; and this high Opening in other Places will give all the Advantage of Winds without their Damage.

When this is done there will be much leſs Danger of Mildew than on other Occaſions, but as it will happen ſometimes in open Fields as well as Encloſures, 'tis plain this can be no abſolute Remedy.

When the Days are hot, and there is little Wind, and the Nights are without Dew, then the Farmer is to watch for Fear of being ſurpriſed by Mildews. On examining he will find when the Miſchief begins, and he will perceive this thick Juice ſticking to the Stalks, Leaves, and young Ears of his Corn. It will diſcolour them, and he will find it firſt by his Eye from that Circumſtance, and then by the Touch, for it will ſtick to his Fingers. The Conſequence of this is, that the Crop withers; the Veſſels that ſhould take in Moiſture from the Air, as well as throw out the abundant Juices of the Plant, are ſtop'd up, and the proper Courſe of Nature is obſtructed. We have explained in a preceding Chapter, in what Manner Trees and Plants are kept in a healthful State, and this free Paſſage of their Leaves, and the reſt of their Surface, is a vaſt Article in their Oeconomy. The Top of the Corn Plant uſually ſuffers moſt by Mildew, and if it remain any Time, though it ſhould afterwards go off, yet the Corn in the Ear never ripens kindly, but is lean and poor, and however the uſeleſs Part of the Plant thrives, the Ear will be light.

It is of Conſequence to the Farmer to know when this Accident happens, for this Reaſon; becauſe whatever Remedy is in his Power muſt be applied in Time, otherwiſe the Miſchief will remain even after the apparent Cauſe is removed.

With Reſpect to the other Means of Prevention they are few, and not very certain of Succeſs; however, as they can be attended with no Damage, it will be right to try them.

The Fields being known where Mildews are moſt likely to happen, there muſt be Caution uſed accordingly.

As Wheat is more ſubject to Mildew in theſe Places, than other Kinds of Grain, and as it is known that the Freſhneſs of Manure makes it the more liable to the Accident, no ſmall Encloſure that has been newly dung'd, ſhould be ſown with Wheat; but it ſhould in theſe Places follow ſome other Crop, as we have ſhewn various Methods of managing it in that Reſpect.

Of all the Kinds of Wheat, that which is called bearded Wheat is leaſt liable to Mildew; this Kind ſhould be ſown preferably to any other, in Places where the Mildew is likely to happen. The Reaſon of bearded Wheat eſcaping better than other Kinds is, that its Juices are thinner, though they be equally rich; ſo that when they are drawn forth by the Sun, they do not hang upon the Plant in that clammy Manner.

This Incident in Nature ſhews the Method of attempting to prevent the ſame Accident by Art, by thinning the Juices of the Plant. Manures take various Effects, and the two contrary are Dung and Soot. Experiments ſhew, that the Juices of Plants enriched by Dung are the thickeſt of all others; and that the Juices of thoſe enriched by Soot are the thinneſt, although the Encreaſe in Grain be as great from one Manure as from the other. For this Reaſon let the Farmer manure with Soot, where he has Reaſon to fear the Mildew; and he may by that Means prevent it.

Thoſe Reaſons have always moſt Weight which

are supported by Experience, and we have its Authority in this Case.

Hertfordshire is the County where most Soot is used as a Manure, and I speak from Experience, that no County is in general so free from this Accident.

Finally, the Farmer will find by examining from Year to Year, his own Crop, that the Wheat which is sown latest is most subject to Mildew; and that which is sown early very seldom suffers by this Accident.

This is a very important Consideration; and he will find it the most essential of all Means for Prevention of this Disorder. Every Advantage is on the Side of early sowing of Wheat, and this among the Principal of them. Mildews come usually at a certain Time of the Summer; and the Corn that is tenderest at that Time, is most subject to be damaged by them; when it has got a certain Degree of Strength, this Accident will not be able to take much Effect upon it.

A good Husbandman, when he sees what will in every Respect most favour his Crops, especially this of Wheat, which is the richest of them all, will provide accordingly, that he may take the Advantage; and of all the Times in the Year he will find the Month of August to be the best for this sowing.

The Farmers who have been taught to believe Mildews came from the Clouds, have been led into a weak Neglect of preparing against them: our Reader, who sees what they are, and how caused, will find on the other Hand that so much may be done to prevent this Mischief, that upon providing in Time for the taking every Precaution, he will be under almost a moral Certainty of their escaping.

If he will give his Enclosures Air Passages, sow his Wheat in them at an early Season, and that after another Crop, not upon Dung, and with the Advantage of Soot Dressing, he will need to have very little Fear of this terrible Accident. It may happen at any Time, and under any Circumstances, for there is no guarding against the Extream of some Seasons; but he will nine Times in ten escape by this Practice; and see his own Fields healthful, while his Neighbours are worth little. We shall, in the succeeding Chapter, shew what is to be done by Way of Remedy when the Accident happens: but 'tis much better to prevent such Accidents as these, than to remedy them, and happily for the Farmer it is much easier.

CHAP. XXV.

Of the Remedies of Mildew.

WHEN the Crop has, by a Neglect of any of the needful Cautions laid down in the preceding Chapter, fallen under the Misfortune of a Mildew, the Farmer is not to give it up at once, as entirely lost, but to endeavour every thing for remedying the Disorder. He could not go about this without the Knowledge we have given him of its Nature, but if he consider this, and observe the Relief he sometimes obtains from Nature, he will be led into a right Path for the helping himself. Art, on most Occasions, does best when it most imitates Nature; but in these Cases there is no Way else by which it can be serviceable.

The Mildew is a thick clammy Moisture, which remaining upon Plants stops their Pores, and obstructs their Growth, and the ripening of their Seeds. Nature washes it off by Rains, and blows it away when dissolved in Dew by Rains.

If Rain and Wind come soon after the Accident, the Farmer therefore knows he has nothing to fear; but a few Days if they do not will be of vast Prejudice to him, therefore this is the Time he is to seize for the doing himself Service.

If a little Rain fall gently, and without any Wind, let him go into his Field and see whether it have done the Business: let him examine the Corn by his Sight and Touch, and he will soon find whether the Remedy sent by Nature has been or will be effectual. If he find the clammy Liquor washed away he may sit down in Peace; but if it remain upon the Corn he may expect Damage, and must prepare to assist in the Remedy.

I have seen when a soft Rain coming immediately after a Mildew has been of the greatest Disadvantage, instead of any Benefit. The Mildew itself has only lodged upon the Tops of some Plants, and on the Stalks and Leaves of others in small Parcels, staining them and corrupting them more or less in those particular Spots. But when such a drizzling Rain has fallen, it has dissolved the thick Juice which caused the Mildew, without being able to carry it off. In this Manner it has spread it in a Kind of Glazing over the greatest Part of the Plant, whereas naturally it would have only affected a few Places. This is the worst Sort of Mildew that can happen; and in this Case, when Nature has taken the first Step, but is not able to perform the whole Cure, Art is to be called in to her Assistance.

In this Situation, which the Farmer will easily know from the Account here given of it, let him send a couple, or according to the Size of the Field, more stout and careful Fellows in: let each of these cut a long, pliant, and well tufted Ash Bough, and leave all the Branches, Shoots, and Leaves upon them, except a few that may be cut off, just for the Convenience of handling them.

Let these Men thus prepared go into the Furrows, dividing Piece by Piece the whole Field between them, and let them sweep off the Wet and Mildew together, with soft Strokes of their Ash Boughs.

These, with their Leaves, will make a Kind of soft and full bodied Brushes, which will sweep off all without breaking a single Stalk. The Strokes are to be made first very gently down, and then with a gentle slanting upwards, carrying on the Boughs a Yard or two before they are brought above the Tops of the Plants. This is a secure and perfect Method of getting rid of the Mildew when some Rain has fallen, and there is no Wind to assist. It does the Business much more perfectly: it is a Way of washing and wiping every Stem; and is in this Manner done with very little Trouble.

When a Mildew is seen upon the Crop, and there comes no Rain to wash it away, the first Con-

Conſideration is, whether there be a good favourable Dew. In this Caſe the ſame Aſſiſtance may be given by Art, as in the other; and the Damage altogether prevented. The Dew will hang in large Drops, and is more eaſily got off than the Rain; and it melts the Mildew as effectually. If it remain till the Sun evaporate it, then the Mildew is left behind, for Heat draws up only Water; but if it be carried off any way before the Sun's Heat take this Effect, the thick Juice, cauſing the Mildew, is carried away with it, and all Damage is prevented.

A briſk Wind, blowing early in the Morning, will effect this; but, if there be none, ſome ſuch Courſe muſt be uſed as in the former Caſe: but as the Dew hangs in larger Drops than the Rain, it will be eaſier diſlodged, and therefore a ſhorter Method may be taken than the bruſhing it off by Aſh-Boughs. To this Purpoſe, a Couple of Men muſt be ſent into the Field an Hour before Sun-Riſe, with a long Cord; they muſt walk in the Furrows at the Diſtance of the Length of the Cord; and one holding one End, and the other the other, they are thus to draw it over the Crop: this will lay ſo much hold, as to ſhake off all the Dew-drops; and the clammy Juice, which cauſes the Mildew, will go with them.

This is a ſhort, eaſy, and expeditious Method, and it rarely fails of Succeſs; no Injury whatever is done to the Corn, and the clammy Juice, thus rubbed off and ſcattered on the Ground, diſſolved as it is in the Dew, ſerves as a kind of Manure; for nothing is richer than it, and the Whole gets to the Root.

In theſe Caſes, we ſee the Boughs or the Cord ſerve in the Place of Winds, to ſhake off the Water in which the miſchievous Matter is lodged. But we have obſerved that, as in ſome Inſtances, there may want Wind, while there is enough Water, ſo, in others, there may want both. There may be no Showers, and the Nights may yield no Dew: this is a Condition nearly deſperate to the Huſbandman: no bruſhing or ſhaking will diſlodge the clammy Moiſture, when it is not diſſolved firſt; and even the ſtrongeſt Winds would, in this Caſe, anſwer no Purpoſe.

As the Office of a Wind may be performed by Art, as we have ſhewn, ſo that of Rain and Dew might, if there were Conveniences; but they are commonly wanting on ſuch Occaſions.

If the Crop be of ſmall Extent, and there happen to be a Pond or Spring of Water near, the Owner may ſprinkle over the Whole with an Engine, with a Fan full of ſmall Holes at its Top; and, after this, the Boughs or the Cord, according to the Exigence of the Caſe, will anſwer the Purpoſe. Thus the Mildew may be diluted and cleared off, by Means altogether artificial: but there ſeldom are Opportunities of doing it: indeed, never in the full Extent in very large Concerns. However, by this the Huſbandman ſees the Compaſs of what he can do, or what he can attempt, and he may ſuit his Operations to the Occaſions.

The Crops of Corn are not the only ones which may require the Huſbandman's Care in this Particular; many other Growths are as frequently affected by it; indeed, all Kinds are more or leſs liable to it, and he is therefore to watch in every Inſtance, and uſe this Precaution for every Particular; which, in many other Kinds, will come more eaſily into Uſe than in this.

We have recommended to him the planting of Hops, and promiſed him very great Advantages from that Crop; but Hops are no more exempt from Mildew than other Growths: frequently they are damaged; and ſometimes they are altogether deſtroyed by this Accident.

There is no Crop needs more careful Watching on this Account. We have laid down the Methods of examining whether it be coming on; and, according to the early Notice of the Miſchief, obtained by theſe Means, will be the Proſpect of Succeſs in the Remedy.

As ſoon as the leaſt Appearance of it is perceived, let the Plants be watched; and, after a Shower, if any falls, or, if not, early in the Morning, while they are wet with Dew, let them be well ſhook, Poles and all; if this do not prove ſufficient, let them be bruſhed with the Aſh-Boughs, taking Care not to hurt them, for it will be eaſy with theſe leafy Bruſhes to wipe over every Part, and not bruiſe or break any.

When there is Rain or Dew, this Method will be ſure of Succeſs in the mildewed Hop-Ground; and when there is neither, the Engine muſt be called in to ſprinkle the Plants.

This may be done very conveniently and eaſily in a Hop-Ground, tho' it can ſcarce be performed at all in a Corn-Field of any Extent; and it will be very well worth the Labour, becauſe it will anſwer a double Purpoſe: it will at once clean the Plants, and water the Ground. This is always uſeful, in the higheſt Degree, to Hops, when the Seaſon is dry toward the Time of their growing to Ripeneſs: and frequently it will happen, that the Produce ſhall be greater after this, than if no ſuch Accident had happened.

CHAP. XXVII.

Of Smuttineſs of Corn.

WE have ſhewn that dry Summers are the moſt ſubject to Mildew; and, on the contrary, Corn is moſt apt to be ſmutty in ſuch as are cold and wet. Indeed, this ſeems one principal Cauſe of the Accident.

When Wheat is ſmutty, the Grains, inſtead of containing a fine white Flour, are full of a black Powder of a diſagreeable Taſte and offenſive Smell.

This is a very unfortunate Accident, becauſe it debaſes the Value of the Grain more than any Thing, and is apt to continue when it has once got footing. Sometimes it thus altogether alters the Colour and Quality of the fine Flour of the Corn, ſometimes it only affects it in Part; but the leaſt Article of this Damage is very much to be dreaded.

Nothing is more eſſential to the Huſbandman than to know the Cauſes of thoſe Accidents which his Intereſt is ſo deeply concerned to remedy; nor is any Thing more difficult for him to attain: for in this, as in other Articles of a like Kind, thoſe who ſhould inform are too apt to miſlead him.

We

We have ſhewn him how, in the Articles of Blights and Mildews, thoſe Inſects, which came to feed upon the accidental Flowing of the Juices from the Diſorder, are ſuppoſed to be the Cauſe of it: and the Caſe is exactly the ſame here.

Mr. BRADLEY accuſes the Eaſt Wind of bringing Inſects, which occaſion this Damage, by eating up the proper Juices of the Corn, and mixing their own with it: and long after Mr. TURBERVILLE NEEDHAM ſhewed the Royal Society, that in all ſmutty Corn there are ſuch Animals.

It is certain, that wherever there is a Corruption, either of Animal or Vegetable Subſtances, theſe Inſects are to be found: but the Farmer is to be told, theſe Writers take the Effect for the Cauſe. The Maggots hatched from the Eggs of Flies in putrified Meat, are no more the Occaſion of that Putrefaction, than the Worms found in ſmutty Wheat are of the Smut. The decayed State of each Kind affords a proper Nouriſhment for theſe little Animals; and wherever there is a Place for them, and Food for their Support, pregnant Nature ſends them. Their Eggs fly about innumerably in the Air, and tho' Millions periſh, thoſe few which happen to lodge where there is a proper Place, will always live, and they will be enough to propagate their Species, and to continue the Miſchief.

It is of the utmoſt Conſequence to inform the Farmer of Errors into which he might be led, reſpecting the Cauſe of theſe Accidents which affect his Crops, for a Miſtake in that fundadamental Article, leads him into an Error in his whole Practice.

If he ſuppoſed, according to thoſe Writers, that Inſects were the Occaſion of Smuttineſs, and that an Eaſt Wind brought thoſe Inſects, he would think he had nothing to do but to plant out the Annoyance, and defend his Fields againſt that Quarter.

We can aſſure him, from Experience, he would not be at all the ſafer from Smut from this Precaution; and nothing is ſo prejudicial as depending upon a wrong Method, inſtead of ſeeking out the right. Many have periſhed miſerably by eating the Liver of a mad Dog as a Remedy for his Bite, whom the Salt Water would have ſaved from that terrible Cataſtrophe. In leſſer and in greater Matters the ſame Caution is to be given againſt depending upon fallacious Remedies.

Having ſhewn the Farmer what is not the Cauſe of Smuttineſs in his Wheat, we ſhall conduct him to a rational Search in order to find what is; for till he knows that he can promiſe himſelf little Succeſs in preventing the Accident.

The more Learned among thoſe who have written on Huſbandry, are they who ſay Inſects are the Cauſe of Smuttineſs; and thoſe of the plainer Claſs attribute it to the Soil: but here our enquiring Huſbandman will find himſelf as much perplexed as ever; one ſaying that it is the Over-rankneſs of the Land which occaſions the Diſorder, as MORTIMER; another, that its Poorneſs is the Cauſe, as BLAGRAVE; and ſome attributing it to both; as thoſe modern Compilers, whom Tenderneſs even to well intended Dulneſs, commands us to ſpare, who have collected without Examination, and wrote down without Thought, the Words of one Author at the Beginning, and thoſe of another at the End, tho' exactly contradictory; forming, without Remarks, a Whole, from theſe diſagreeing Parts.

As ſome of the practical Writers attribute the Smuttineſs of Corn to the Qualities of the Land; others lay it on the Conduct of the Farmer: ſome of theſe tell him, that the laying rotten Vegetables on the Ground, by way of Manure, is the Occaſion of Smut in the Wheat, as WORLIDGE; who by that Obſervation would terrify the Farmer from the Uſe of a very good, cheap, and harmleſs Manure: and others inform him, that ſmutty Seed raiſes a ſmutty Crop, and ſo attribute all to the Choice of the Seed-Corn.

Among this Variety of Sentiments, all adopted by Writers of ſome Reputation, the Farmer knows not which to chuſe or credit: and ſo unhappily is he circumſtanced, that wherever he fixes among them he will chuſe wrong. We have ſhewn him what has been ſaid, that he may avoid paying too much Regard to it; and ſhall, after this, direct him, by his own Obſervation, to diſcover the Cauſe of the Diſorder; after which he will rationally proceed to the finding a Remedy.

CHAP. XXVIII.

Of the real Cauſe of Smut.

THE enquiring Huſbandman will firſt ſee, on examining the Nature of ſmutty Corn, that there is a great deal of Difference in the Diſorder, according to the Degree of it. When it is in the full Height of its Miſchief, the whole inner Subſtance of the Corn is black as Ink, of a faint, nauſeous Taſte, a bad Smell, and of offenſive Qualities, occaſioning Sickneſs in thoſe who eat Bread made of Flour in which there was much of it. In this Caſe, if the Corn be bruiſed, and ſteeped in Water, it preſently ſhews innumerable Worms, like little Eels, living in every Part of it.

When the Diſorder is not arrived to this full Height, the inner Subſtance of the Corn is not then entirely hurt, but the Outſide is ſpotted with black; and, in ſome Corns, a Part of the Flour within. This makes a great Change in the Matter; for the firſt is wholly deſtroyed, whereas the other may ſometimes be recovered for certain Uſes, though not for all Services.

When our Huſbandman underſtands this Difference in the Degree of the Diſorder, let him firſt recollect what his Memory will recall to him, as to the Circumſtances of former Years, and then examine the preſent: this Way and this only will lead him to the Truth.

He will remember that there have been certain Seaſons when a great deal of Corn was ſmutted; and others, where very little ſuffered that Accident. Let him call to Mind the particular Circumſtances, and he will find that all thoſe Years, when there has been ſo much of the ſmutty Corn, were cold and wet; and that thoſe which ſhewed leaſt of this Accident, have been the hot and dry.

This firſt Principle then will be eſtabliſhed in Reaſon, upon the Teſtimony of Experience, that

a cold

a cold wet Summer is one principal Cauſe of Smuttineſs in Corn: and this will be of great Uſe, as it will aſſiſt in explaining to him the particular Cauſes; and warn him when he is moſt rationally to expect the Damage, and therefore when he is to guard againſt it.

England is more ſubject to this Diſorder of Corn than any other Country we know; and this is owing to the ſame Cauſe, our frequent wet Summers: in the warm and naturally dry Countries it is not known at all, or not in a Degree worth Notice.

In Egypt no Age ever ſaw a black Grain of any Corn; for in Egypt they have no Rain: and even in Italy it is little regarded now; and was ſo ſlighted in earlier Time, that all the Roman Writers have not a Name for it. There is not a Word for Smut in the Latin Language. The Reader muſt not cenſure this Aſſertion, if ſome modern Writers, in that Language, have attempted to name it: they uſe Words which properly expreſs Blight and Mildew: to both theſe the old Roman Fields were ſubject, therefore they have Terms to expreſs them; but this was little known, and leſs regarded.

When our Farmer has led himſelf into a juſt Knowledge of the Cauſe of Smut, let him add Obſervation to the Information of his Memory.

In a wet Summer, let him examine his own Crops, and thoſe of his Neighbours, and obſerve whoſe Corn is infected with this Malady, and in what Degree.

We have made the Obſervation ſo ſtrictly before him, that we can inform him what will be the Reſult of his Enquiry. He will find a great deal of Corn infected with the Accident in theſe Summers; and that moſt which is upon the pooreſt Land, and the wetteſt. Theſe are the two Things that concur with an unfavourable Summer, to occaſion Smut, and he need look no farther for the real Cauſe.

He will perceive that in moſt Grounds there will be ſome ſmutty Ears, ſuch a Seaſon; but in the pooreſt and wetteſt, moſt; in proper and well managed Land he will ſee but few, and thoſe ſmutted, in general, but imperfectly; a very ſmall Part of them will have the Diſorder in its full Force, having the Corn converted to a black Duſt, the reſt will only be here and there ſpotted on the Surface. Next let him examine a poor Land, not particularly wet, and he will ſee moſt of the Corn there ſpecked and ſpotted, tho' but a ſmall Part is abſolutely rotted with the Smut; but in a Field that is poor and wet both, he will find the greateſt Part perfectly ſmutty.

This will be the natural Reſult of the Soils and Seaſon; and from this he will form a Judgment of what Smut is, very different from what he has read; ſuch is the Difference between reading, in general, and ſeeing; and he will no longer attribute the Diſorder to Inſects or Eaſt Winds, but ſee it as a natural Effect of an unfavourable Seaſon upon an unkindly Soil: he will ſee cold and wet Summers the principal Occaſion; and he will find alſo that they take moſt Effect where the Huſbandman has been leaſt regardful of his Duty: and he will thus be led to a proper Conduct.

He will perceive in the ſame Kind of Soils a great Difference in the Degree of the Diſorder, and this will lead him to examine into the Occaſion; which he will find to be the better Management in the Article of ſowing; and the Change or the Preparation of the Seed: theſe are Articles we are to enquire into in a ſucceeding Chapter; 'tis enough that we have here led him to find by his own Remembrance and Obſervation, what is the true Cauſe of Smut, and ſettled him in a right Notion with Reſpect to ſo much of his Conduct.

He will now know, that neither the Richneſs of the Land in general, nor any Kind of Manure in particular, are the Cauſe of Smuttineſs in Corn, though both theſe have been aſſerted; and he might have been miſled by ſuch Accounts. He will therefore not be afraid to enrich his Land in general, nor to uſe any Kind of Manure in particular; but will know, that the Seaſon is the great Cauſe of the Malady, and that it takes moſt Effect on the pooreſt and the wetteſt Grounds: therefore he will bend his Mind to the draining and enriching thoſe Lands he ſuſpects moſt as being liable to Smut; and will conſider that every thing which impoveriſhes his Land is a Cauſe of this Diſtemperature; and every thing that puts it in Heart, is a Defence againſt it.

CHAP. XXIX.

Of the preventing of Smuttineſs by a due Care of the Land.

WE are now acquainted with the Cauſe of this Accident; and therefore are in a rational Way of guarding againſt it. In order to this every Thing is to be done that can give Strength to the Crop. The two Things that make Land afford abundant Nouriſhment are Tillage and Manure; and of theſe great Tillage is the beſt for the preventing this Diſorder.

We ſpeak here from Experience; we have ſeen Lands, where no Care about the Seed and other Articles could prevent frequent ſmutty Crops, which have yet been cured by repeated Plowings.

As Smut may ariſe from theſe ſeveral Cauſes, a too abundant Moiſture, a Poorneſs of the Land, and an ill Conduct in the ſowing, let them be ſeverally guarded againſt by the careful Huſbandman, and he will have the farther Encouragement to be careful in this Reſpect; that every thing he is to do to prevent Smut, will alſo enrich and improve his Land. He will by this rational Conduct not only ſecure to himſelf a cleaner, but a larger Crop.

In the firſt Place, if his Land be poor let him uſe the ſeveral Methods we have before related for the Improvement of it; and if it lie liable to Wet let him lay it high, and cut the Furrows deep and in proper Direction. This we have explained at large already, ſo that it needs only be named here. 'Tis enough that we tell him it is to be done; we have elſewhere ſhewn him how to do it.

As a great deal of Tillage is the beſt Way of en-

enriching Land to prevent Smut, it follows that the Horſe-hoeing Huſbandry is particularly calculated to prevent this Damage; and what is thus pointed out by Reaſon is alſo confirmed by Experience; for upon repeated Examination we have found, that Land managed in this Method is not nearly ſo ſubject to ſmutty Crops, as that in the common Courſe of Huſbandry.

But as we no where recommend Tillage alone, but on every Occaſion would have the Improvement of Land owing partly to this, and partly to Manure, it is needful here to ſpeak of the Kind of Dreſſings that are moſt proper. We have directed the Farmer already to adapt his Manures to his Soils in a general Way; and that is a Point he muſt always keep in his Memory: but as this does not tie him down to any one particular Dreſſing for any one Soil, he has ſtill a Choice, which, though it does not go through the whole Range of theſe Materials, yet is enough to be very ſerviceable to him on the preſent Occaſion.

As he ſees that Dampneſs has a very great Share in the occaſioning of Smut, he ſhould chuſe the dry and warm rather than the fat and moiſt Manures: thus freſh Dung is one of the worſt Dreſſings for a Piece of Land inclined to ſmut the Corn; and of all that can be choſen, Lime is the moſt proper.

We have named the two Extreams; the Farmer will know there is a great Variety of Articles between them: let him take any of theſe according to the Nature of his Land, and the other Circumſtances.

In this Point Experience confirms, as in the others the Dictates of Reaſon. Upon an Enquiry among the moſt experienced Farmers in different Counties, we find that there is no Part of the Kingdom ſo free from Smut as Derbyshire, where they uſe a vaſt deal of Lime; and in general, that the Places where it is moſt common, are thoſe in the Neighbourhood of great Towns, where there is Abundance of Dung uſed in the Dreſſings.

Thus far we have conſidered the Article of preventing Smut, by a due Care of the Ground; the Reſult of which is, that the Farmer who knows where the Danger lies will beſt guard againſt it, by keeping his Land in good Heart by warm Manures and frequent Tillage, and by laying it in ſuch a Manner that it may have the moſt Advantage poſſible of the Sun, and the leaſt Damage from Wet; according to the Rules we have laid down in their Place upon thoſe different Heads.

CHAP. XXX.

Of the Prevention of Smut by the Conduct in Sowing.

WHEN the Farmer has prepared his Land for the Reception of his Seed Corn, ſo as to have it the leaſt likely to be damaged by Smut, he is to conſider what will tend to make the Crop liable to it, and what will be moſt likely to defend it againſt that Accident in the Article of ſowing. The Crops which are moſt ſubject to it, are ſuch as are ſtarved, and ſuch as are chilled: againſt the chilling of them we have ſaid all that can be needful in the preceding Chapter; and the Directions we have given about the Uſe of right Manures and frequent Tillage, will tend greatly to the preventing their being ſtarved; but the Farmer will recollect that there is another Article which always tends to the impoveriſhing a Crop, which is the ſowing the ſame Seed again and again upon the ſame Ground.

Whatever tends to the impoveriſhing the Crop, always tends in the ſame Degree to the ſubjecting it to Smut. This is a plain Reſult of what we have ſhewn before, that the Poorneſs of the Growth, from whatever Cauſe it ariſes, is one of the two great Sources of Smut.

The Change of Seed Wheat is very eaſy, becauſe it is every ones Intereſt; and as the Farmers of different Parts are to be mutual Gainers by it, they will doubtleſs be ready at all Times to do it: in this we ſhall only give the general Caution, that the Farmer on both Sides behave with Integrity, ſending in his beſt Corn in the Exchange; for nothing but that can keep up the Credit of this uſeful Intercourſe.

There has been an Opinion, that ſmutty Grains will grow up into a ſmutty Ear: but this is an Error; for they will not grow at all. However, they will do juſt as much Damage in the Ground as if they did: for if many of them be ſown among better Corn, they will ſpread the Infection of their Juices in the Land, and produce the ſame Effect as if they could grow themſelves; or indeed worſe, becauſe they will infect farther.

In the Caſe of ſowing Wheat, among which ſome is ſmutty, the Effect is this: the ſmutty Grains break and diſſolve in the Ground, at the ſame Time that the others ſwell and ſhoot out their firſt Roots: when theſe are juſt taking in their firſt Nouriſhment, the rotted Corns of the ſmutted Kind afford their Juices to them: they take in this, and it gives a Tendency to Smuttineſs in the whole.

The Farmer thus ſees a very plain Reaſon againſt ſowing Corn that has any ſmutty Grains among it; it is indeed worſe upon this true Principle, than upon that falſe and fooliſh one others have aſſumed, of thoſe Grains growing.

This will ſtand as a Caution to the Huſbandman, that when he ſends Corn in Exchange, he does not for his Credit Sake ſend ſuch as has any Smut among it; and that when he receives Seed Corn in Exchange from another, he look it carefully over, before he prepare it farther for ſowing.

A clean Seed is ſo neceſſary on this Occaſion, that he ſhould not ſuffer a Grain to be ſowed that has the leaſt Speck upon it; nor any that has been waſhed or otherwiſe cleaned; for it is not certain, nor indeed probable, that any cleaning of Grain once ſmutted, can make it fit for this Purpoſe.

This Caution being eſtabliſhed in the Examination and picking of the Seed Corn, the Advantage will be very great in the receiving it from another Part of the Country. Nothing

can prevent a Piece of poor wet Ground ſown with ſmutted Corn from being ſmutty; but in the common Courſe of Things, a Crop that would have been liable to this Accident from any apparent Cauſe, will be much more likely to eſcape, if the Seed have been chang'd. This always makes the Growth, under equal Circumſtances, more vigorous; and we have ſhewn that the heartier it is, the more ſafe it always is from this Accident.

Worlidge, and other of the earlier Writers, with one Voice recommend this Change of Seed for the Prevention of Smut; and Mr. Tull propoſes it as the great and certain Remedy.

We ſhall not miſinform the Farmer ſo far as to join Mr. Tull in calling it a certain Remedy; for upon a long Examination of this Matter we have found, that though very uſeful with other Precautions, it will not do alone. This is the worſt Error a Farmer can commit: in depending ſo far even upon a good Article as to omit all others: he is truſting to one Aſſiſtance where he may have many.

It is certain the Change of Seed is a very good and highly uſeful Method; but theſe ſeveral other Precautions we have named have a Right to the ſame Regard. Mr. Tull ſupports his Aſſertion by the Experience of a Gentleman, who changing his Seed with one who alſo chang'd his own every Year, in ten ſucceſſive Years, though ſeveral of them were wet ones, never had one ſmutty Ear in his Crop, though he uſed no other Precautions. He adds, that in ſome of thoſe Years, thoſe who uſed every other Method of Prevention had a great deal of ſmutty Wheat, while he eſcaped. This would tend to lead the Farmer to depend upon the Change alone; but Mr. Tull, though a very honeſt Man, is a very warm Writer; and thoſe Authors are to be read with proper Allowances.

The proper Conduct is to adhere ſtrictly to this uſeful Caution of changing the Seed, without depending upon it alone: and having thus eſtabliſhed the general Practice upon Reaſon, we ſhall examine into the Particulars.

Every Change of Seed will be of Service, both againſt Smut, and in Favour of the general Growth; but the Nature of this Exchange being being well conſidered, the Advantage may be doubled. The Soil makes a great deal of Difference in the Condition of the Corn for ſowing; and Reſpect is to be had to it for that Reaſon.

In general, the Wheat that has grown on a dry ſandy Ground ſhould be all ſold for eating; for it never ſucceeds ſo well as that from other Soils, either upon the ſame Ground again, or upon any other.

As the ſandy is the worſt Land for getting Seed Wheat for a Change; ſo the beſt is that which is of the moſt oppoſite Kind; this is the clayey: and this is not only ſhewn by Reaſon, but teſtified alſo by Experience.

Upon whatever Land Wheat is to be ſowed, there is none ſo proper to bring it from as a tough, firm Soil, that has a good deal of Clay: it will thrive in a Land of the ſame Kind, in a Loam, or even in a Sand.

When the Soil is clayey to which the Wheat is to be brought, none is ſo proper as one of the ſame general Nature; but the whole ſhould not be in every Reſpect alike, becauſe that will be like ſowing the ſame Corn upon the ſame Land, and will abate, if not deſtroy the Advantages of the Exchange. The Colours of clayey Soils uſually ſhew their Differences: and by them we may judge on this Occaſion.

A white Clay is the beſt Soil to take Seed from that is to be ſowed on a red; and a black Clay furniſhes the beſt Wheat for a yellow: in the ſame Manner, interchangeably, the Wheat that has grown on yellow is good for black; and that from red for the white. Theſe, however, are Niceties that need not be obſerved where there is any Difficulty. In general let the Farmer get his Seed from a ſound Soil at a Diſtance from his own Land; and if he can, let him get it of ſome one who changes it yearly himſelf. This, though alone it may be liable to Smut, like other Corn, yet would be leſs ſo than others: but a Seed of this Kind ſown on Land prepared as we have directed, will be abſolutely ſecure.

In the common Courſe of Huſbandry, the changing of the Crop upon any one Piece of Land, is another needful Caution to prevent Smut. This depends on the ſame Principle with the Reſt: often ſowing the ſame Crop on a Piece of Ground makes it weaker; and where Wheat is weak, any Unfavourableneſs of Seaſon will make it ſmutty.

But in the Horſe-hoeing Method this Change of the Crop to the Ground is not neceſſary, tho' a Change of Seed from ſome other Place is. The Reaſon is plain, that in this new Method, tho' the ſame Field be ſown with Wheat ten Years ſucceſſively, the Growth will never be any two Times in the ſame Place; ſo that while the Crop is encloſed in the ſame Hedges, yet it annually grows in a different Parcel of Ground. We can aſſure the Farmer from Experience, that is ſufficient; for if the Seed be changed every Year, though the ſame Field be thus ſown with Wheat ever ſo long, not an Ear of it will ever be ſmutty.

Having thus directed the Farmer in the Choice of his Seed, and the ordering of his Ground, for making his Crop free from Smut, we ſhall in the next Chapter ſhew him in what Manner he is to order it for the ſowing; and ſhall conclude the preſent with one certain and practical Obſervation, that of twenty Crops which are ſmutty, nineteen, if not all, are owing to bad Management or Careleſſneſs in one Article or other of the Preparation.

CHAP. XXXI.

Of preparing the Seed againſt a ſmutty Crop.

THE Practice of ſteeping Seed Corn, which has of late been ſo greatly recommended, and is become ſo univerſal, is in no Article more ſerviceable, than in preventing of Smut. When the former Precautions have been taken for the procuring the right Seed, and dreſſing the Land in a proper Manner, if this be added there is little Fear of Succeſs. In general, the earlier

Wheat

Wheat is ſowed, and the better it is ſteeped before ſowing, the leſs it is liable to be ſmutty. The Reaſon will be obvious to the Reader, who conſiders what we have ſaid of the principal Cauſe of Smut, which, next to the Badneſs of the Seaſon, is the Weakneſs or Poorneſs of the Crop: now early ſowing naturally makes the Growth ſtrong, at a Time when others who have ſown late have it much weaker, becauſe Time never fails to give it this Strength: and the Advantage of ſteeping is juſt of the ſame Kind; for it makes the Crops more vigorous. Let any one look into the ſeveral Fields in a wet, cold Summer, that has ſmutted a great deal of the Wheat, and he will be ſure to find the pooreſt in other equal Circumſtances has ſuffered moſt.

Of the various Methods that have been propoſed for brining of Seed Wheat, there is no Need to uſe any on this Occaſion, but the plaineſt and moſt familiar. Receipts are publiſhed abundantly, in which Copperas, and Allum, and Urine, and the like offenſive Ingredients are recommended; but this is the Act of Fancy, not of Judgment. Moſt think they ſhew the more Skill, the more Ingredients they can crowd into their ſteeping Liquor; as thoſe old Phyſicians, who in the Compoſition of Mithridate and Venice Treacle, ſeem not to have conſidered what would be beſt for the Purpoſes of the Compoſition, but how many Things they could get into the Preſcription.

We would have our Farmer underſtand the Meaning and Deſign of every Thing he does, and he will then find all this Parade is Quackery, the Jargon of a Stage Doctor to conceal Ignorance. Thoſe who do not know which Ingredients uſed in the ſeveral Receipts for ſteeping Liquors are beſt, may put in all, that they may be ſure to have the right among them: but the intelligent Farmer ſhould know the Intent of each, that he may be able to chuſe with Wiſdom on any particular Occaſion.

In the preſent Caſe, all that he expects from the Brine or Steeping Liquor, is to give the Plants a ſpeedy and firm Growth; let him therefore reject all thoſe Ingredients, which have been, as we have ſhewn before, introduced for other Purpoſes; and let him in the preſent Caſe uſe thoſe which tend to promote the Growth only. Theſe are only two, Salt and Lime, and therefore all others are to be rejected.

For this Purpoſe therefore, neglecting all thoſe Receipts which are crowded with uſeleſs, and much more thoſe which are loaded with offenſive Ingredients, let him manage in the following plain and eaſy Manner: firſt let him pour the Seed Wheat into a large Tub, and pump a good Quantity of Water upon it: let him ſtir it well about with a Stick; and then leaving it to ſettle pour off the Water, and pour away all the light Grains that ſwim upon the Top with it.

Then let him pump more Water upon it, and ſtir it about; and repeat the ſame till it has been waſhed four Times: by this Means the Wheat will be well damped and perfectly clean, and every light Grain will be ſeparated from it.

When the Wheat is thus ready for ſteeping, prepare the Brine in the following Manner. Pump a ſufficient Quantity of Water into a Tub that has a Tap to it, and put in as much Salt, weighing what is put in, as will, when diſſolved, make the Brine ſo ſtrong that an Egg will ſwim upon it. This is juſt half the Strength that is required; therefore let as much more Salt by Weight be put in, and let all be well ſtirred about till it melts.

When the Salt is all melted put in the Wheat and ſtir it well about. Let it lie two Nights and a Day, that is, put it into the Brine one Evening, and it will be done enough by the Evening but one afterwards. When it is taken out of the Brine, let it be well covered with ſifted Lime, and then it is ready for ſowing.

This plain and eaſy Method is found by repeated Experience, more ſucceſsful than all the perplexed and complicated Brines; and it is the original Way directed by the Accident that occaſioned it. The firſt brined Wheat ſown in ENGLAND was the Freight of a Ship, which ſunk near the Shore. The Cargo was ſaved after it had lain ſometime under the Salt Water; and being ſown it produced better than any other in the Neighbourhood. This opened the Eyes of the Farmers to a very material Improvement. The Lime is the only Addition required to it; and this, which ſome think only uſeful as it prepares it for ſowing more conveniently, yet is of much more eſſential Service. Every one knows the Advantage of Lime as a Manure; and there is no Way of uſing it ſo beneficially.

CHAP. XXXII.

Of the cleaning of ſmutty Corn.

THE Farmer ſees what he is to do to prevent Smuttyneſs in his Crop; and we will venture to promiſe him, that if he follow the Inſtructions in every Article, he ſhall have very little Reaſon to complain from that Source: but we are to conſider that he may, before he gets into the Uſe of this Method of Prevention, have a ſmutty Crop, and we are not to leave him uninformed of the Methods by which he is to make the beſt of it.

Thoſe Ears that ſhew themſelves to be utterly rotted, and converted into a black Powder, ſhould be picked out; and when theſe are ſeparated, the reſt may be managed in the following Manner.

Let the whole Quantity be put into a very large Veſſel, and Water in abundance poured upon it: let it be very well ſtirred about in the Water with a new Birch Broom, and this repeated ſeveral Times with freſh Waters, till all the Blackneſs is got off, and the Wheat looks like other Corn, only for the Wetneſs. Then ſpread it upon Sheets, or any other cleanly Way, to dry in the Sun, and turn it from time to time till it be dried perfectly; after which it will be fit for Uſe.

This is by no Means to be uſed as Seed Wheat, that we have ſhewn before, for the leaſt Remains of the Smut would endanger the new Crop; but provided the worſt of it have been carefully picked out firſt, there will be no Harm in the uſing it for Bread, or any other Purpoſe.

We have obſerved that Wheat, where ſmutted to a great Degree, is unwholeſome; and indeed in that Caſe it ſhould not be eaten; but when the Defect has been moderate, and the worſt is picked out, the Remainder may be eaten without Danger.

In ſome Places they have a Way of ſoaking their Wheat in Water for ſeveral Hours, in order to get off the Blackneſs, by rubbing it afterwards in the Water; but when Corn is ſo bad as to require this, it is, honeſtly ſpeaking, too bad to uſe.

In this Caſe, as the Water has penetrated the very Body of the Grain, the Sun and Air will not be enough to dry it. They for that Reaſon put it to dry in a Kiln, in the Manner of Malt, and afterwards ſell it; but this every one ſhould be guarded againſt, not only with Reſpect of ſowing, but for the common Service, as the Bread of Families.

In Reſpect of Seed Corn that ſhould be of the choiceſt and pureſt Kind of all, ſo that any Impoſition upon the Farmer in the ſelling for that Purpoſe, is cruel in the higheſt Degree. When he is obliged to buy his Seed Corn, he muſt be very nice in the Examination of it; and he may diſcover whether any Trick of this Kind, more or leſs, have been play'd with it, by the Sight and Taſte. Fine and perfect Wheat ſhould look ſhining, and all of a Colour; if it be dim on the Surface, or of different Hues in the ſeveral Grains, it is to be ſuſpected. The ſweet Taſte of good Wheat is alſo very well known to the Farmer, and no Art can give this to ſuch as has been waſhed or otherwiſe managed to hide its Faults.

In Flanders they go farther than the late named Practice in the clearing of their Wheat that has been ſmutted; they have a large hollow Machine, made of Plates of Tin ſet in a wooden Frame. Theſe Plates are all pierced full of Holes inward, ſo that the Inſide is in all Reſpects like the rough Face of a Nutmeg-grater. When their Corn is ſmutty in any great Degree, they firſt ſteep and waſh it very carefully in Water, and then, when it is ſomewhat dried, they put it into this Machine and work and ſhake it about; the Conſequence is, that the black Spots are in Part grated off, and in Part concealed; and this, though none can be deceived in it, ſo far as to buy it for Seed Corn, is ſold for Bread, and is often the Occaſion of great Diſorders.

Our Cuſtom of picking out the worſt Ears firſt, takes away the Neceſſity of any ſuch Contrivance for the rubbing the Grains down; but in general, when it is ſo bad as to require this, the Farmer has more Occaſion to blame himſelf than any thing in the Seaſon.

The great Article in order to prevent the Miſchief, is the uſing a proper Kind of Manure, and a due Quantity of it, with a due Degree of Tillage. And we may be led, by farther Examination of the ſeveral Places where particular Manures are uſed, to know which agree beſt and which worſt, with the Intention of preventing Smut. A great deal we have done in this Matter, by examining the Crops in ſuch Places as we have had Opportunities to viſit; and by making Enquiry by Letter in others: but it would be of the utmoſt Service to the Improvement of this uſeful Study, if thoſe who have Judgment and Experience in the ſeveral remote Countries, would communicate their Knowledge for their mutual Benefit. The Proprietors of this Work will be very glad to be inſtrumental to ſo general a Good, and as it is now drawing toward a Concluſion, they take this Opportunity of offering their Service, and ours the Compilers of it, to review and prepare for the Publick Service any Papers or Letters which ſhall be directed to them, containing any Branch of uſeful Knowledge.

Having thus gone through the Care of the Land, and Management of a Crop under every Circumſtance, nothing remains for the compleating this Part of our Work, but the informing the Farmer how he may beſt preſerve his Corn when he has reap'd and thraſh'd it; and this we ſhall give in the Words of a Correſpondent, to whom we have been often before obliged on the moſt intereſting Occaſions, and whoſe Diſcoveries and Improvements on this Head demand the Thanks of the Publick, more than the Labours of moſt other Enquirers.

A

DESCRIPTION

OF A

Ventilating Granary,

For the Preſervation of Corn in a State of Reſt; with the Plan and Conſtruction of it: Alſo, ſome Obſervations and Directions about ſound, and tainted or ill-ſaved Wheat, with Reſpect to their Preſervation in this Kind of Granary.

Principles upon which this Granary is built.

AIR, conſequently Dryneſs and Coolneſs, duly adminiſtered together, with ſufficient Security againſt Vermin, ſeem to be the Eſſentials neceſſary to the moſt convenient Methods of preſerving Corn, for all its Uſes, for ſeveral Years together in a Granary or Magazine, without ſtirring.

N. B. A Granary or Magazine, on theſe Principles, ſhould not be built in a confined Situation; as, near the Shade or Shelter of Trees or Buildings, but where the oppoſite Eaſt and Weſt Sides of ſuch Granary may be properly expoſed to thoſe Points: in which Caſe moſt of the intermediate Points between them and the North and South, will act upon this Granary more or leſs, according to the Velocity of the Wind, by fixing the Folding-Doors thereof properly, at ſuch Times when the Corn is to be ventilated.

References to the Plan.

Plate 1. Elevation of the Granary or Magazine to be built of Brick or Stone, of various Dimenſions, according to the Occaſions of the Owner; but here (as a Specimen) only 46 Feet long by 17 broad, from Out to Out.

Pl. 2. Section of the Granary Lengthways through the Middle.

Plan of the Garret floor

J. Myatt sc.

Engraved for the Compleat Body of Husbandry Published by the King's Authority in Weekly Numbers at 6.d each.

B. B. B. B. The Garret, all in one Chamber, into which the Corn may be received by Means of a Crane or Pully fixed over the Door (k) (Plate 1) on the North Gable of the Building; to which Door a Ladder, or Flight of Stairs on the Outside of the said Gable may communicate. This Garret may occasionally be made Use of as a Store Room for Corn, that has already been preserved two or three Years in the Chambers below, marked (C. C. C.) or for other Kinds of dry Goods, leaving a few Air Holes only in the Gable Ends of this Garret Story.

C. C. C. Three Chambers where the Corn is to be first reposited, in order to receive the necessary Ventilations for a Year or two, or more, till perfectly cured or sold; each Chamber here, about 13 Feet square, by 12 high; to be divided from each other by Brick Partitions (m. m.) carried up from the Ground. The Sides of these Chambers to be neatly covered with Stucco Plaister.

G. G. G. The Floors of these Chambers, to be supported with whole double Deals laid Edgeways, and covered with narrow Deal Boards, not exceeding six Inches in Breadth, leaving a Space of near an Inch between each Board, that Room may be given for the Air to ascend equally through these several Interstices in the Floors, in order to ventilate the Corn contained in these Chambers, as Occasion requires. (vid. Plate 3. Fig. 1.) These Floors, or at least the Interstices between the Boards, to be covered with close Wire Grating, that will not admit the Grain to pass through; or the Floors may be covered intirely with a proper thin, but strong Hair Cloth, nailed down round the Confines of the Floors, before the Corn is lodged.

G. G. G. Small Trap Doors (vid. Pl. 3. Fig. 1.) to be made a Foot square each, one in the Center of each Floor; which may be opened occasionally, to let out the Corn into the Ground Chambers for Use or Sale; and may at such Times, if a brisk Wind sets in and through the Ground Chambers, prove a good Winnowing to such Corn to prepare it for Market, especially if the said Trap Doors be humoured by the Hand, so as to let fall the Stream of Corn thin and diffused on the clean Ground Floors. These Trap Doors to be free from Wire Grating or Hair Cloth over their Dimensions; to be affixed by Hinges, so as to open into the Ground Chambers; at other Times kept fastened with a cross Iron Bar Staple and Pad-Lock, to prevent Imbezelment. The Ceilings of the Chambers C.C.C. must be made as much Air Proof as may be, either by some excellent close Plaister Ceiling, or only by caulking the Joints in the Garret Floor above, pitching the Seams afterwards, and dashing drift Sand on the Seams after the hot Pitch Brush, by which Means no Air can pass out of the Chambers C. C. C. except through the Flues (L. L. L.).

L. L. L. The Flues, to be made of a Piramidal Figure, with Beams erected at the four Angles of each Flue, well barred and braced together, and covered with Laths and Plaister, so as to be tight and Air-Proof; to be four Feet square each at their Bases, and well fixed in the Garret Floor, and to the Roof Timbers; to be erected directly over the Trap Doors (G. G. G.) and elevated twelve or fourteen Feet above the Ridge of the Roof of the Building; their Openings at their Tops to be a Foot square each; a Piece of Brass Net-Grating to be fixed half an Inch within their Muzzles, to prevent Sparrows, or other Annoyances descending to the Corn below, and also to admit of a Cover or Valve, falling close on their Muzzles. These Muzzles to be well guarded from Rain and Snow by proper Umbrelloes, elevated a little above them, and well fixed to the Continuation of the four Beams of the Flues. The Valves just mentioned to be made of square Pieces of Oak Board, exceeding the square Dimensions of the Orifices of the Flues, by two Inches on every Side; a Plate of Lead of five or six Pound weight, to be nailed on the Top of each Valve; the Valves underneath to be lined with Buff, well soaked in Pickle, to attract the Moisture of the Air, swell and stop close. These Valves to open or shut by Means of a small Cord, fastened to a very short cross Sling of the like Cord, which cross Sling communicates, and is made fast to four Staples in the four Corners of each Valve; that the Valves may be raised and lowered evenly on their respective Muzzles, by Means of the small Cord passing over a Pully fixed under the Center of the Umbrello, and down between the Lath and Plaister; and the boarded Lining of the Flue comes out to hand in the Garret, through a small Hole in one Side of the Flue, which Hole should be made through a Piece of Wood fixed in the Framing of the Flue; and the upper Edge of the said Hole, on the Inside of the Flue, should be guarded by a small Roller of Wood, to ease the Friction of the Cord upon drawing up the Valve, and keeping it in that Situation by a Weight somewhat superior to that of the Valve itself, hung to the Cord End in the Garret, or the Cord may be made fast to a Hook in the Garret Floor, making Allowance for the lengthening and shortening of the Cord by the Weather, that it may not be in danger of breaking; these Valves or Covers should also be guided in their raising and lowering, by four fixed upright smooth wooden Bars, which may lodge them equally on the Squares of their respective Flue Mouths. These Valves or Covers might be contrived to be opened and shut by other Methods, but this seems to be one of the most simple, and least liable to Disorders and Repairs. The chief Use of these Valves (and a very considerable one) is the keeping out the moist foggy Air from descending upon the Corn, when the Granary is not to be ventilated.

i. i. i. Trap Doors in the Garret Floor, for laying in the Corn into the Chambers C.C.C. to be two Foot and half square each, well fitted to their receiving Jambs, and made tight with Clay well tempered with Salt and Water, after the Chambers are charged with Corn.

D. D. D. The Ground, or lowest Chambers that should be admitted in a Building of this Nature, the Sides of which to be smooth plaistered, that Rats or Mice may not be able to ascend to the Corn Floor, nor should any Goods or Lumber be admitted into these Ground Chambers, because they would diminish the Diameter

of the Quantity of Air to be admitted into them, and conſequently of its Weight and Preſſure neceſſary to force its Way up through the Interſtices left in the Corn Floors, as before deſcribed.

E.E.E. Large folding Doors to each Ground Chamber, opening outwards, which when ſet open and properly fixed may catch the drying Side Winds, and direct them into their reſpective Chambers. The like folding Doors to be on each Side of the Building, Eaſt and Weſt, oppoſite to each other, ſo that upon ventilating the Corn above, the Windward Doors only are to be opened; at all other Times, when moiſt Weather prevails, all the Doors, as well as the Valves before-mentioned, to be kept ſhut and cloſe as poſſible; for which Reaſon theſe folding Doors are to be truly fitted to their Jambs, as alſo to their upright center Poſts where they meet, bolt and lock, or by a ſtrong croſs Bar and Pad-Lock on their Outſide; and the Borders of theſe Doors, at all their Meetings on the Inſide, ſhould have a Liſt of Buff nailed round them with Sprigs, in order to prevent an Indraught of moiſt and foggy Air, as much as poſſible.

Mice and other groſs Vermin, will find great if not inſuperable Difficulty, to get Admittance into this Granary; and Inſects infeſting it, may be deſtroyed by Brimſtone ſet on Fire occaſionally in the Ground Chambers, keeping the folding Doors, as well as the Valves above, cloſe ſhut at ſuch Times of ſtoving, and it ſhould be well ſtoved before it be repleniſhed with Corn.

It is ſufficient only to remind many People, that the Acid Fume of Brimſtone confined, kills all Inſects within its Circulation, and no Doubt diſcourages their Approach for ſome Time after; and may probably tend to abate Fermentation in the Grain, which is generally, if not always, occaſioned by ſuperabundant Moiſture and Heat.

Reasons *offered for the Operation and Effects of this* Ventilating Granary.

When the dry ponderous Air is directed into the Ground Chambers by their folding Doors, and ſtrongly preſſed in by the continued impelling Force of its own Current; being there accumulated, it will endeavour to expand itſelf on every Side, by its own elaſtick Spring: and ſo paſſing through the Interſtices, before-mentioned, in the Floor above it, as the leaſt reſiſting Vents will inſinuate itſelf through the Wire Grating or Hair Cloth, into the numerous Interſtices between the Grains of Corn; through which its Motion will be greatly expedited by Means of the Flues above, when open; as the Air at their Tops being above forty Feet from the Ground, will be much rarer than in the Ground Chambers below, where it will be greatly condenſed by the Preſſure of the ſuperincumbent Atmoſphere, and alſo by the impelling Wind or Current of Air continually driven into the loweſt Chambers. The Air therefore, always endeavouring to expand itſelf in the loweſt Chambers, to thoſe Parts where it finds leaſt Preſſure and Reſiſtance, will continually tend from the loweſt Parts upwards, and ſo produce an adequate Circulation of Air through the whole Bulk of Corn, whereby it will be ventilated and kept cool, dry, and ſweet, though in a State of Reſt, for ſeveral Years together, and longer than the private Owner ſhould lie out of his Money.

Farther Obſervations on the Uſefulneſs of this Kind of Granary.

In this Kind of Granary, Wheat may be lodged in Bulk ten or twelve Feet ſquare every Way, or whatever the ſquare Contents of the Corn Chambers be, the Wheat may lie therein within a Foot, or half a Foot of the Ceiling, but half a Foot is a good Diſtance at firſt laying in the Corn, for it will ſoon ſink lower as it dries. This is a vaſt Advantage in Stowage over the old Granaries, where they dare not lay the Wheat, for a long Time after laying it in, above eighteen or twenty-four Inches deep, and that too, frequently turned and aired by Hand-Labour and Expence, for Fear of its heating, muſting, and breeding the Wevil; whereas this Kind of Granary, ventilated as it were, per ſe, and in a Manner without any Trouble or Expence attending it, will preſerve at leaſt five Times the Quantity of Wheat upon every Foot of its Flooring, more than the old-faſhioned Granaries can do.

N. B. The Ground Chambers need not be above ſeven Feet high, under the Floor Timbers; and a Brick Floor, or one of Clay, Lime, and Smiths Duſt well tempered together, is fitteſt for the Ground Floor.

In large Military or Publick Magazines, greater Bulks of Corn may be ſupported by upright Props under the Floors, and the Ventilation proportioned by adding more Flues to each Corn Chamber, and proportioning the Dimenſion of the folding Doors thereto, or the Number of them.

The Author having never ſeen or heard of any Granary of this Kind in Practice, ſubmits it to publick Scrutiny, Cenſure, or Improvement.

The Diſtinction and Difference between ſound and tainted or damaged Wheat, and their different Treatments in Order to their Preſervation in this Kind of Granary.

If Wheat be dry and well ſaved at Harveſt, free from black, blighted, or ſooty Ears, has afterwards had its due Sweat and Melioration in Rick, Cock, or Barn, for five or ſix Months, and after threſhing out has been well cleanſed and ſcreened; ſuch Wheat may truly be called ſound, and when lodged in this Kind of Granary, may be eaſily preſerved therein for many Years, by ordinary and moderate Ventilations.

For Inſtance, being thraſhed out in January or February after reaping, well cleanſed, and lodged in this Granary; it may be ventilated once a Week, if Opportunity offers, for the firſt two or three Months in Spring, which will be a great Advantage to the Grain, before the ſultry Heats of Summer come on, when it ſhould be ventilated as often as a proper Breeze or Gale of Wind offers, and once a Month, a few Matches of Brimſtone ſet on Fire in the Ground Chambers, as before directed; in the Autumn, the Winter, and Spring following, two or three Times a Month may be ſufficient to ventilate, without applying the Brimſtone Fumes; but the ſecond Summer ventilate twice or thrice a Month, and

apply the Fumes once or twice during this ſecond Summer; after which Time it may be ſufficient to ventilate once a Month during the ſecond Autumn, Winter, and Spring, and twice a Month during the third Summer, when it may be ſaid to be thoroughly cured.

It may not be amiſs, during the firſt Year or two after the Wheat is lodged in this Granary, to inſpect the Condition of the Corn, by opening the Trap Doors in the Garret Floor, eſpecially in Summer Time once or twice; for as Moiſture or Vapour of the Corn will always riſe to the Surface of the Bulk, though the Center may be dry, ſo the Appearance of the Surface, as to Moiſture or Dryneſs, may regulate the Number of Ventilations neceſſary for its Preſervation.

It is certain from Experience, that ſound Corn that has been well preſerved in common Granaries, by frequent Turnings and Winnowings, and afterwards laid two or three Foot deep, or more, ſeldom ſweats, gives, or ferments after the firſt two Years, except it receive accidental Wet or Moiſture, from which it is eaſily freed with a little Care; whereas it is a long Time parting with its natural internal Moiſture, which is the greateſt Enemy to its Preſervation.

It is no leſs certain that Wheat, being well preſerved by any Method whatſoever, has, after ſeveral Years ſo kept, been found to produce more and better Flour for Bread, than ſome of the ſame Field and Crop did ſoon after its being threſhed out; becauſe the aqueous Humidity of the Grain evaporating by keeping ſome Years, the Flour comes cleaner from its thin Bran under the Stone.

It is equally certain, that Wheat ſo preſerved for ſeveral Years, has proved very good Seed Corn, and probably not ſo liable to produce the ſmutty Ear; Exceſs of Moiſture, either in the Seed, the Soil, or the Seaſons, being the chief Cauſe of that grievous Complaint, except the Seed itſelf be ſmutty, and then the Crop alſo will be ſmutty notwithſtanding dry Seaſons.

But if Wheat has been ill-ſaved at Harveſt, or be in a contrary Condition, in any or all Reſpects, to the ſound Wheat deſcribed above, which would certainly give it a ſtrong Tendency to Heat and Fermentation, in a Bulk of ten or twelve Feet deep, and ſo induce the Wevil, and other Maladies, to the further Damage or Deſtruction of the Wheat. It will therefore, in this Caſe, be neceſſary firſt to cleanſe well by Screen or Tryer, after which give it a very gentle and ſlow drying upon a Kiln, equal only to a ſtrong Sun Heat, till the Grain be ſomewhat hard under the Teeth; then laying it on a Floor to cool, for ſome Hours, put it into Sacks half filled and tied faſt, and ſo rub the Wheat well therein on a ſmooth Floor with both Hands, frequently turning the Sacks over every Way, in order to looſen and free the Grain from its black ſooty Duſt; then winnow clean, after which it may be laid into this Granary ten or twelve Feet deep, and there treated in every Reſpect like Wheat originally found.

Such Wheat, after ſuch Treatment, will turn out much better for Bread, though kept two or three Years or more in this Granary, and ſell for a good deal more Money than it would have fetched in its firſt tainted and foul Condition.

Yet ſuch Wheat, though by this Method made proper for Bread, ſhould by no Means be uſed for Seed; for Kiln-drying, more or leſs, abates or deſtroys its vegetative Quality; and even without drying, a diſtempered Seed ſeldom or never fails of producing a diſtempered Crop.

The INTRODUCTION.

WE have thus, according to the Courſe and Method marked out in our Plan, gone thro' every Article of the Farmer's Concern reſpecting the Choice of his Cattle for Stock; and the Growth and Management of every uſeful Plant that he ſhall have Occaſion to cultivate. We come now to conſider thoſe Diſorders to which the ſeveral Kinds of Cattle are liable, the Methods of guarding againſt them, and the Medicines moſt approved in their Cure.

We have had Occaſion to obſerve, on many Occaſions, how greatly the Farmer is miſ-led by thoſe who ſhould give him Information in reſpect of the Management of his Crops; but this is an Article leſs underſtood, and more injudiciouſly treated than any other; and it is, at the ſame Time, of the greateſt Concern. The Loſs of his Cattle is not to be recruited but

at a very conſiderable Expence; and the Care of them is, in general, committed to Perſons ſo very ignorant, that little better than their abſolute Loſs can be expected when they fall into any conſiderable Diſorder. They muſt have Strength indeed, and good Luck into the Bargain, if they can eſcape from their Diſeaſes and ſuch Doctors.

Unhappily, while thoſe Perſons who undertake the Cure of theſe Creatures are ſo ill qualified to ſucceed in it, the Farmer himſelf is leſs able to judge right, than they are to act. It is a Part of needful Knowledge fartheſt of all removed from his Enquiries, and he is obliged to ſubmit to every thing.

A few Names of Diſorders got by Rote, are generally the whole Stock of the Country Leeches Knowledge, and theſe he applies at Random to any Diſorder that comes before him, boldly, becauſe he knows none can contradict him.

A ſmaller Store of Remedies ſerves his Purpoſe, than of Names for the Diſorders; for theſe are People who, like the advertiſing Doctors, cure many Diſeaſes with one Medicine. Their Phyſic they uſe as much at Random as the Names of Diſorders; and the unhappy Farmer is ſtripped both of his Cattle and his Money by their Ignorance. If they deſtroy the Beaſt, which would, if let alone, have of itſelf recovered, he is perſuaded the Violence of the Diſorder killed it; and ſatisfies his Mind that he has done all he could.

This is the Condition of the Knowledge Country Pretenders, in general, have of the Diſeaſes of Cattle: 'tis impoſſible to repreſent it worſe than it is; but from this Condition of Ignorance we hope to reſtore it in the ſucceeding Chapters.

We ſhall inſert in them nothing but what is the Reſult of Experience. We ſhall inform the Owner what he may do for his Cattle himſelf, and lay down ſuch plain Rules for the Conduct of others, that he will be able to know whether they act according to Reaſon and Knowledge.

If the Practitioners will ſtudy in the ſame Pages, we promiſe them, they will find only Truth and what Experience confirm: we requeſt them to peruſe 'em carefully, not only for the Farmers Sakes, but their own; and hope they will conſider the Harſhneſs of what we have been obliged to ſay, as no more than a juſt Repreſentation of their Need for better Information: 'tis one of thoſe Wounds that is neceſſary to be opened deep, in order to reach the Cauſe of the Malady; and they know theſe ſoon heal when proper Methods are followed.

The Freedom we have taken with their Profeſſion, is to let the Farmer into his Danger, in repoſing too much Confidence in their Knowledge; for it is for his Service we are writing: at the ſame Time we ſhall obſerve, that there are many particular Practitioners of more Knowledge; and to theſe we refer what we ſhall publiſh on the Subject, deſiring them to be Judges between us and their more ignorant Brethren, whether they do not deſerve all we have told the Farmer concerning them by their raſh Practice, and whether what we ſhall propoſe to them be not founded on the true Principles of the Art. We write for real Uſe, and have no Reſpect of Perſons.

The Horſe is the moſt valuable Creature in the Farmer's Stock, both with Reſpect to his Price and his Uſe. The whole Care of chuſing, managing, and breeding this Animal, we have delivered in a preceding Part; but, in this Place, he claims a very particular Regard, both for the frequent Diſorders to which he is liable, and the familiar and eaſy Methods by which the fat greater Part of them may be remedied, when they are rightly underſtood.

We ſhall give Directions for preparing the ſeveral Kinds of Medicines uſeful on ordinary Occaſions; and we ſhall alſo enter upon the worſt Diſeaſes to which he is ſubject, not contenting ourſelves, in the cuſtomary Way, with ſetting down the Name of the Diſeaſe, and then the Remedy for it; but explaining what it is, before we give Directions what ſhould be done to cure it. Without this, all that can be written is uſeleſs; and this has been the Reaſon that from what has hitherto been publiſhed on this Matter, ſo little Good has accrued, or ſo ſmall a Share of Knowledge has been communicated either to the Farrier or the Farmer.

CHAP. I.

Of the Glanders.

WE have taken for the firſt Conſideration, under the Article of the Diſeaſes of Horſes, this which is the moſt important of them all, and, in general, the leaſt underſtood.

Many have called it incurable; and indeed, according to the old Practice, it muſt have been ſo: for if ever a Horſe recovered under that Management, Nature muſt have performed the Cure: it is impoſſible they ſhould ſo much as have aſſiſted in it, who knew nothing of the Seat and Nature of the Diſeaſe.

Of late Years ſome Perſons of Skill have undertaken the Cure of Horſes; Anatomy has been called in to aſſiſt in the Operations; and Diſſections made of morbid Bodies of that Animal, to ſhew the Cauſe, Situation, and Nature of their Diſeaſes.

From this rational Method of Study, we have been made acquainted with the Origin and true Nature of the Diſorders of theſe Creatures, and thence may proceed properly to the Cure.

With Reſpect to the Glanders, this was more wanted than in Regard of any other Diſorder; and it is but very lately we have attained the Knowledge. A Farrier to the King's Stables in Paris, his Name Lafosse, made the Diſcovery; and the Royal Academy of Sciences received and adopted it. This is the true Road to Knowledge; when the moſt honourable Aſſemblies will receive and give their Sanction to Truth, from every Hand that offers it; and do Honour to any one who can do Service to the Public.

CHAP. II.

Of the miſtaken Notions concerning the Glanders.

THE Glanders is a Diſorder ſo well known, that it may ſeem ſuperfluous to give any Account of its Appearance; but nothing is leſs underſtood, in general, than its Cauſe.

It is a Running at the Noſtrils. Firſt there is a whitiſh Liquor diſcharged; afterwards, as the Diſeaſe gathers Strength, a browniſh Matter; and, laſt of all, a bloody Water.

All theſe are voided in very great Quantities, ſo that the Horſe is offenſive to the Sight, and the Diſcharge waſtes him continually.

This is the Diſeaſe called the Glanders, which has deſtroyed Thouſands of Horſes; and from which very few have eſcaped that were once ſeized with it: not that the Diſorder is incurable, but that from a univerſal Miſtake, concerning its Nature, none knew how to go about to cure it.

The Reader will be aſtoniſhed, that among ſo many Conjectures as have been made about this Diſeaſe, none came near the right; and that People ſhould ſearch in the remoteſt Parts of the Body for the Seat of a Diſorder, which all the Time was ſituated where it appeared.

The various Opinions that have been advanced concerning the Origin and Nature of the Diſeaſe, have occaſioned various and almoſt innumerable Methods of treating it to be propoſed, and theſe Opinions being all erroneous as to the Cauſe, it is no Wonder that not one Horſe was ever cured by the Methods eſtabliſhed on thoſe Principles. Where the Truth is not known, wrong Gueſſes are endleſs; and all that is founded upon them muſt be alſo erroneous.

The oldeſt Authors on theſe Subjects, ſuppoſed the Seat of the Diſorder to lie in the Brain; and they imagined that, at laſt, the Brains themſelves run out thro' the Noſtrils, and to that attributed the Death of the Creatures: miſtaken and erroneous as ſuch an Opinion was, theſe were got nearer the Place of the Diſorder than many who followed.

The next Conjecture was, that the Diſeaſe lay in the Back-Bone; and that the Diſcharge thro' the Noſe proceeded from the Marrow of that Part. This was a received Opinion many Years among our Farriers, and is ſo, in moſt Places, to this Day; from whence they call the Diſorder, The Mourning of the Chine.

Later Authors have ſuppoſed the Diſeaſe to be in the Liver, ſome in the Lungs, ſome in the Kidneys, and others in the Spleen: to all theſe proper Remedies have been propoſed; and the Glanders has been attempted to be cured by Diuretics and Deobſtruents.

Mr. SOLLEYSEL, an Author of great Credit, adopts all theſe Parts as poſſible Seats of the Diſorder; and traces the Matter by Way of the Cæliac Vein, up to the Head, where he ſuppoſes it is lodged upon the Parotid Glands, and thence diſcharged through the Noſtrils. This appeared ſo learned, that it was ſuppoſed it muſt be true: People are always ready to reverence what they do not underſtand; and the Farrier and the Farmer thought nothing could be a Secret to a Man who could uſe ſo many Words they never heard before. On this was founded a Practice for the Cure, which, like the reſt, was as ineffectual as the Syſtem was erroneous.

After this, the Lungs were conſidered as the Seat of the Diſorder. Others attributed it to Knots and Swellings under the Caul: the Authors of the Dictionary of TREVAUX, adopt the former of theſe Opinions; and the latter is found among the Syſtems in our Mr. CHAMBERS.

We have named theſe ſeveral Opinions, to tell the Farmer that they are erroneous. Experience, Diſſections, and certain Obſervations, have ſhewn they are falſe: let him therefore take Care that he is not miſ-led by them, and that he place no Dependance upon the Methods of Cure founded upon them.

In general, all internal Medicines are uſeleſs in this Caſe. The Horſe may have a bad State of Blood at that Time, and this may render the Cure, in the Method here to be propoſed, more difficult. In this Caſe, the common Sweetners of the Blood may be properly given at the Time he is under Cure; ſuch as Brimſtone and Antimony among his Corn, but otherwiſe they are not wanted.

CHAP. III.

Of the real Situation and Cauſe of the Glanders.

AFTER all that has been written plainly or pompouſly, learnedly or ignorantly, on this Subject, it is plain from obſerving the Nature and Progreſs of the Diſorder, and from the fruitleſs Attempts founded on theſe Opinions to remedy it, that the Cauſe does not lie either in the Brain or the Back-Bone, the Liver or the Lungs, the Spleen or the Kidneys.

Anatomy, Obſervation, and a certain and regular Method of Cure, founded upon thoſe Experiments and Obſervations, prove that the Seat of the Diſorder is where it appears; that no Part of the Creature is affected but the Noſtrils; and that the Diſeaſe really lies in the Glands, which are ſituated in the thin Skin that covers their Inſide.

When the Glanders are only in one of the Noſtrils, a ſtrict Examination ſhews that the Gland, or, as Farriers call it, the Kernel, which lies near the Jaw-Bone on the ſame Side, is found to be ſwelled and inflamed, and not that on the other Side; but as ſoon as both Noſtrils run, then both theſe Kernels are found to be ſwelled in the ſame Manner.

This Diſorder may very naturally proceed from a Cold, without the Blood's being at all concerned in it; though it may happen, in other Caſes, that the Blood is bad at the ſame Time, and then the Diſeaſe will be more difficult to cure.

When theſe Kernels are inflamed, the Running at the Noſe comes on, and this is the firſt and gentleſt

gentleſt Stage of the Diſorder. The Horſe's holding down his Head to feed, and its natural Situation, combine to increaſe this Running; and thus a Diſorder is begun in a natural Way, and continued by natural Means, which is generally ſtrengthning itſelf, while the Farriers are attempting its Cure by Drenches; not one of which can poſſibly have the leaſt Effect upon it, becauſe they are levelled at an imaginary Cauſe.

For the Satisfaction of thoſe who would not part with the Opinion of the Glanders proceeding from Diſorders of the Lungs and Spleen, or the Liver and Kidneys, all theſe Parts have been examined by Diſſection, in Horſes that have died with the Diſorder upon them in its utmoſt Violence, and they have been found all ſound: therefore it is plain they have no Share in the Cauſe: it lies wholly, as we have ſhewn, in the Parts where it appears. It may come from a ſimple Cold in the Horſe, without any other Diſorder to cauſe it; tho' it may alſo, in ſome Inſtances, be occaſioned by the Matter of a Diſeaſe falling upon that Part; or be rendered worſe by a bad State of the Blood. In theſe, which are particular Caſes, the Method of Cure is however to be the ſame with the ſmall Allowances we have made already on that Head, of a bad State of the Blood; as to the other Caſe, it requires no particular Conſideration; for though a Diſorder of another Kind may have been the Cauſe of the Glanders, by ſettling on that Part, yet, when once ſettled there, it is the ſame as if the Glanders had come in a natural Way; and the ſame Method will prove a Remedy.

To explain the Seat and Nature of the Diſorder perfectly to the Farmer, we are to inform him, that there is a thin Skin which lines every Part of the Noſtrils of a Horſe. This is the Seat of the Glanders. He will obſerve in the Noſe of a Horſe, a Partition going all along the Inſide, which divides it into two Parts, or the two Noſtrils. This Partition is covered in every Part with the Skin we have named: it is thin, ſoft and tender; and in it there are many ſmall Kernels. Theſe ſeparate a ſoft Moiſture for rendering the Skin ſupple and ſenſible; and this is all they are to do in their natural State; the Abundance of their Diſcharge being a trifling Thing, and thrown off without Offence: but theſe Kernels will, by being diſordered, ſeparate a larger Quantity of a fouler Matter, and this is the Glanders.

On each Side of the Partition which divides the two Noſtrils, there are large Holes or Cavities. The ſame Skin which covers the Partition itſelf, is alſo continued to them, and forms a Covering to their Bottoms and Sides; but in this Part, the Kernels are fewer and ſmaller than elſewhere, and they only ſeparate a very ſmall Portion of the Moiſture for juſt keeping the Skin there ſoft.

This is a very happy Proviſion of Nature; becauſe the loweſt and innermoſt Parts of theſe Hollows are ſo deep and winding, that if any Redundance of the Matter had been ſeparated there, it could not have been diſcharged as in the other Parts; and Nature would have been loaded and obſtructed by the remaining of it upon the Place.

The Skull of a Horſe is compoſed of ſeveral Parts; and in that Piece which forms the Forehead, juſt above the Place of the Eyes, there is a Space or Gap between the two Plates of the Bone: theſe make what are called the frontal Sinus's; but the Farmer, without troubling himſelf with remembring ſuch Names, will underſtand that there are ſuch Cavities; and this will be enough for his Purpoſe.

Theſe Cavities are covered throughout on the Inſide with this ſame Skin, which covers the Partition of the Noſtrils; and it has in this Part the ſame Sort of Kernels as elſewhere.

All this Skin, and all the Kernels in it, are the Seat of the Glanders. In the Beginning, the Kernels only ſwell, and diſcharge a great deal too much Matter; and theſe in the Hollows of the Forehead-Bone moſt of all. They are therefore the main Seat of the Diſeaſe. When it becomes more violent, they are ulcerated or grow full of little Sores; then they diſcharge a more offenſive Matter; and at length the whole Skin of this Part is enflamed, ſwelled, and eaten to Pieces, and then comes the Diſcharge of a bloody Matter.

This is no fancyful Suppoſition, but is the exact and real Fact found by Examination.

When the Head of a Horſe, violently affected with the Glanders, is opened, not only the Kernels are found to be ſwelled and ſore, but all this Skin is full of Ulcers; and it is ſeen to be grown much thicker than naturally, and fuller of Blood-Veſſels; and theſe are eaten to Pieces at their Ends. From theſe flows the Blood, and from the ulcerated Glands the Matter, which are ſeen to come from the Noſtrils of the Horſe in this Diſorder; and this is the true Nature and Cauſe of the Diſcharge: the Glanders is nothing but this, extending itſelf over every Part.

We have told the Farmer of the natural Hollows there are on each Side of the Partition of the Noſtrils; and have obſerved, that Nature, in a State of Health, occaſions ſo little of the natural Liquor of the Kernels to be ſeparated here, that it ſerves only to moiſten the Skin, becauſe if more were ſeparated there, as in other Parts, it could not be diſcharged, and would be a Burthen to her. This Miſchief happens in the Caſe of the Glanders.

The Kernels in theſe Cavities are diſordered like the reſt; they grow ulcerated, and they diſcharge a great deal of Matter, which lodges, againſt the Intent of Nature, in theſe Hollows, and they are found full of it in a very offenſive Condition, on the diſſecting the Heads of Horſes dead with this Diſeaſe.

In the ſame Manner alſo, the Kernels which are in that Part of the Skin which lines the Sides of the Hollow in the Forehead-Bone, grow ſwelled, enlarged, enflamed, and ulcerated; and the Skin itſelf grows thick, raw, and bloody. All this joins to confirm the Truth of that Syſtem, which places the Seat of the Glanders in this Skin, or Lining of the Noſtrils and its Glands, and declares it not to be in the Liver or elſewhere; becauſe in all Diſſections of Horſes dead

dead with the Glanders, this Skin and its Kernels are found thus ſwelled, inflamed and ulcerated, and the Entrails are, as we have ſaid, at the ſame Time found perfectly ſound and good; unleſs when the Creature has had ſome other Malady beſide.

Theſe Hollows of the Forehead Bone in Horſes dead with the Diſorder, are found, like thoſe by the Side of the Partition, full of thick offenſive Matter: and the Change in the Skin itſelf is greater here than in any other Part. In a Horſe that has died without the Glanders, this Skin upon Diſſection is found to be thin, fine and ſoft, and there is never ſeen in it any Blood Veſſel: doubtleſs there are ſuch, though too ſmall to be perceived by the Eye; but in this Caſe of a Horſe dead with the Glanders, the Skin in this Part is thick, hard, and inflamed; and there are Blood Veſſels ſeen all over it, with their Sides and Ends eaten to Pieces. In each Noſtril are two Subſtances rolled up like Horns, and in the ſame Manner covered with the Skin which covers the Partition, and lines the Cavities; and in this Part this Skin is in the ſame Manner found to be enflamed, thickened, full of Blood Veſſels, and ulcerated.

By this it is plain, that as the Skin we have deſcribed is the real Seat of the Glanders, ſo it is univerſally affected by that Diſeaſe whenever it appears, and no Part of it eſcapes.

The Diſeaſe firſt ſhews itſelf in thoſe Parts of this Skin where the Kernels are biggeſt, and this is particularly the Caſe in the Hollows of the Forehead Bone; ſo that they may be called in a particular Manner the Seat of the Diſorder: but it purſues its Courſe through the whole Extent of that Membrane.

It is in general much the ſame Structure that we find upon Diſſection in the Head of a Horſe, and in that of one of our own Species: but there is a particular Difference in thoſe Glands or Kernels we have mentioned under the Jaw Bone, which one by one ſwell, as the Diſeaſe affects firſt one, and then the other Noſtril.

There are the ſame Glands or Kernels in Men, and Anatomiſts call them the Sublingual Glands: but it is particular, that in Men they open into the Hollow of the Mouth; ſo that whatever they diſcharge is ſpit out, or otherwiſe managed as the Spittle: but in Horſes they do not open into the Mouth, but turn backwards, and paſs behind the Holes of the Noſtrils.

The Mouth in Mankind is in a great Degree moiſtened by theſe Glands; and to ſupply that Office in Horſes, as theſe have their Opening turned another Way, there are innumerable ſmall Kernels all over the Inſides of the Lips. Now though the Kernels we have juſt named are ſwelled in the very firſt Appearance of the Glanders, yet the others within the Lips are not at all affected: the Diſeaſe not being concerned with the Mouth, but only with the Glands of the Skin of the Noſtrils.

It alſo appears to be a Diſorder ſolely and particularly of this Skin and its Kernels; for it very rarely ſpreads to any other Part. In the extreme Degrees of the Diſeaſe, the Partition of the Noſtrils which is covered by this Skin will be eaten, by the Sharpneſs of the Humour thus ſurrounding it on every Side; but no Diſſection ever ſhewed any other Bone to be affected by the Diſeaſe.

The Farmer who conſults his own Reaſon upon the Reſult of all that has been ſaid, will be convinced, in Spite of all that the whole Liſt of his favourite Authors have written, that the Seat of the Glanders is entirely and only in this Skin of the Noſtrils, and its Kernels: and he will thence be led to purſue the Cure upon the only rational Plan, the attempting it only in that Place.

If the Liver, the Lungs, or the Brain, or any other of theſe Parts, were the Seat of the Diſeaſe, the Creature muſt be pining, and diſordered in other Reſpects beſide this; and ſooner or later would be carried off; whereas we ſee on the contrary, that this Diſorder ſhews itſelf on Horſes otherwiſe in perfect good Condition; and that when it has rendered them unfit for better Services, and they are delivered over to Hackney Coachmen, they live a long Time with it, and ſhew no Sign of any other Diſtemper. This, and the healthful Appearance of thoſe Parts when the Horſe is opened, ſhew that nothing there has been either the Cauſe of the Diſorder, or has been ſo much as affected by it.

CHAP. IV.

Of the Cauſes of the Glanders.

WE have ſhewn the Farmer what this Diſeaſe is, and ſhall from that Explanation naturally lead him to the proper and only Method of Cure: but as every thing here is practical, we ſhall introduce between theſe Conſiderations ſomething as to what may be the accidental Cauſe of it.

The Glanders may ariſe from a common Cold, as a ſtuffing up of the Noſe in our own Species is the common Effect of the ſame Accident; and in this Caſe the firſt Approaches of the Diſorder are to be guarded againſt, for they may be ſtopped, and that Miſchief eaſily prevented, which it will be, after it ſhould get rooted, very difficult to cure.

Thus, when a Horſe has got a Cold, and it falls upon his Noſtrils, let the Farmer remember that the Glanders are ſituated in this Part, and that a Cold is their natural Beginning. Let him remember that every Cold which falls upon this Part may ſettle into that terrible Diſorder, and conſequently take the firſt Care to remove it.

He will perceive when a Cold ſeizes this Part, by the Horſes ſnorting and frequently toſſing about his Head, and afterwards by the Noſtrils being more than ordinarily wet.

In this Caſe nothing is ſo natural as its turning to the Glanders. If the Horſe be in a feveriſh Diſpoſition at the ſame Time, the Skin and its Kernels will enflame as well as ſwell, and all the Symptoms may very naturally follow.

This may give our Huſbandman a juſt Notion of the Danger of a Cold to his Horſes: a great Phyſician, when his Patient told him he had only a Cold, anſwered, "Would you have the Plague?" and there is the ſame Reaſon for conſidering that Diſorder in the moſt ſerious Light, when it affects Horſes.

If it ſeize upon the Noſe let the Horſe be immediately blooded largely: then give him twice in the Day a good warm Maſh, and ride him gently afterwards. Keep him warm and clean, and the next Day give him the common Purge.

If this do not anſwer let him be blooded the Day after, as largely as at firſt, and purſue the ſame Courſe one Day more, and it rarely fails.

I have practiſed this myſelf, and I have recommended it to others; and I am certain with the greateſt Succeſs. I have all the Reaſon in the World to believe I have prevented the Glanders in many a Horſe; and can ſay with the greateſt Truth that I never had one, ſince I have followed this Practice, that has fallen to that Diſorder, which I reaſonably attribute to taking this Care in Time.

A Cold ſeizing upon the Noſe is not the only Thing that may cauſe the Glanders. A Surfeit may very naturally take the ſame Effect. This fouls the Blood, and produces groſs Humours in Abundance; and theſe may very naturally be diſcharged by the Kernels in this Skin, ſuch being their natural Office. This may ſwell, inflame, and ulcerate the Skin of the Noſtrils, and be an immediate Cauſe of the Glanders; and in this Way that Diſeaſe would probably be more dangerous than any other Way, and more difficult of Remedy.

In this Caſe however the Method of Cure muſt be the ſame, only with this Caution, that Sweeteners of the Blood muſt be given at the ſame Time. If this Caution ſhould be omitted the Diſorder might break out in the ſame Place again.

A farther Caution muſt be given the Farmer, that before he attempts to cure a Horſe by the Method to be delivered in the next Chapter, he be aſſured that the Diſorder is what he takes it to be: if he will obſerve carefully the ſeveral Symptoms we have ſet down, he cannot be deceived; but he muſt take Care that he do not ſuppoſe every Running at a Horſe's Noſe to be the Glanders; for in that Miſtake he may ſometimes ſet about a troubleſome and harſh Method of Cure, for a Diſorder that would perhaps have gone off of itſelf, or with a ſingle Bleeding; or he may, in ſome Caſes, attempt to remedy that which is, in its own Nature, incurable; and in the End diſgrace the Method, becauſe it would not cure a different Diſeaſe.

To explain this more fully, he is to obſerve the Difference between a Cold ſettling upon the Noſtrils, and the Glanders. We have ſhewn this may bring on the Glanders, but it is not that Diſeaſe itſelf, and ſlighter Methods will cure it. On the other hand, an Abſceſs in the Lungs may diſcharge itſelf at the Noſtrils of a Horſe, and this, though it on a ſlight Obſervation reſemble the Glanders, yet is altogether diſtinct in its Nature, Origin, and Situation; and therefore cannot be reached by the proper Cure of that other Diſeaſe.

When a Horſe runs at the Noſe, let the Farmer obſerve the Nature and Colour of the Matter. If this be ſharp, corroding, and ill-coloured, it looks like the Glanders, therefore let him next look into the Inſide as far as he can; and if he perceive the Skin ſwelled, inflamed, and full of little Sores, there is little Room to doubt of its being this terrible Diſorder. Let him next obſerve whether it runs continually, which if it does it is another Proof; and laſtly, let him examine the Horſe in all other Reſpects, and if he find him in every other Circumſtance well and healthy, he may conclude with Certainty that this is the Diſeaſe, and proceed to the Cure.

On the other Hand, if the Matter be thick and white, and the inner Part of the Noſe not inflamed or ulcerated; and if it run very little while he is at reſt in the Stable, and encreaſes on his being put to work; and finally, when he has a Difficulty of Breathing, and a rattling in his Breaſt as he takes his Breath, all theſe Symptoms conſidered together, will ſhew that the Diſeaſe is not the Glanders; but an Abſceſs in the Lungs.

This is a Diſorder which the proper Method of Cure for the Glanders cannot reach, therefore it will be vain to try it; and indeed, as nothing can cure ſuch a Malady, it is in vain to attempt any thing for it.

CHAP. V.

Of the Method of Cure for the Glanders.

WE ſee that the Glanders is a Collection of Ulcers in the Skin of the Inſide of the Noſe, and its Glands: this is the whole Fact; and knowing this we may advance rationally to the Cure.

The only Method of effecting this muſt be by cleanſing and freeing the Parts from the Lodgment of this ſharp Matter, and the healing of theſe ſeveral Ulcers.

That might be done in the ſame Manner as external Sores are cleanſed and healed, but the Difficulty is how to come at theſe for the dreſſing, cleanſing and healing them. It is plain this cannot be done by the Noſtrils, for there is no Way of getting freely and properly at the Complaint by this Method, therefore the firſt Thing is to be to make the Opening to the Place where Nature has not given any. We know now that the principal Seat of the Diſeaſe is the Glands or Kernels of this Skin, within the Cavity of the Forehead Bone, and we are to proceed accordingly.

When the Skull is cracked, and beat in by a Fall or Blow in our own Species, the Surgeon cuts a Hole through it in another Place, that he may have Way to come at the depreſſed Part within. This Operation is very terrible but very ſafe: it is practiſed continually, and with Succeſs. What we are ourſelves able to endure, certainly this coarſer Creature may. On this has been founded the only rational Method ever laid down for the Cure of the Glanders.

A Hole is to be pierced through the Skull of a Horſe, in ſuch a Place as is leaſt liable to Inconvenience, and moſt properly ſituated for the throwing in proper Liquors to the Seat of the Diſorder.

The firſt Conſideration in this Reſpect is, whether the Glanders be ſeated only in one Noſtril, or whether it have ſeized on both: if only one be affected, then one ſuch Opening through the

Skull will be enough: if both Noſtrils be infected with the Diſorder, then two ſuch Openings are to be made, one for each.

The Place for this Opening to be made therefore is, on one Side or both Sides the Head. It may be done without the leaſt Inconvenience or Hurt to the Creature, and it will give a free Paſſage to the neceſſary Applications. The beſt Place for the Hole to be opened is at ſome Diſtance below the Eye; and there is not the leaſt Danger from the Operation.

In the performing it on the Human Species, if any bad Conſequences ever attend it, they are not owing to the cutting a Hole through the Bone, but to the injudicious Hand of the Operator hurting the Brain in doing it. Now in Horſes the Brain does not come ſo low as to the Eyes; and therefore in making two Holes, or more if neceſſary lower down, there is not the leaſt Danger of any bad Accident.

The Safety of this leading Operation being thus ſhewn, the Uſe of it is evident. The proper Liquors for waſhing and cleaning of the Parts, are to be thrown in at theſe Openings by a Syringe; and the Holes are to be ſo made that the Syringe being pointed upwards, the Hollow in the Forehead Bone, which we have ſhewn to be the great Seat of the Diſeaſe, may be thoroughly waſhed by it. It would be very much to be wiſhed, that the opening could be made juſt where this Hollow of the Forehead Bone is; but that lies ſo high that a Farrier might do Miſchief. The Brain is ſituated there for the Part is conſiderably above the Eyes, and more toward the Middle of the Head, but it will anſwer every good Purpoſe of this Method if it be made lower, and the Liquor be thrown up into it. In this Method one Aperture or Hole may be made to anſwer the Purpoſe in moſt Caſes, though there will not be the leaſt Diſadvantage in making two or more for better Convenience.

Though the Cavity or Hollow in the Forehead Bone lies higheſt; yet the Hollows we have deſcribed before at the Sides of the Partition of the Noſtrils are the moſt difficult to be well cleaned. Upon two Principles alone turns the whole Method of Cure in this Caſe; the firſt is, that there be a Way by which the Liquor intended for waſhing and cleanſing the Parts can be conveyed to them through a Syringe; and the other is, that when the Matter is thus waſh'd off from the Skin and its Kernels, there be a Paſſage for the Liquor and that foul Matter to go off freely together.

Now in Reſpect of the Matter lodged in the Hollow of the Forehead Bone, that being waſh'd away by the Liquor from the Syringe will very freely and naturally diſcharge itſelf, together with that Liquor, out at the Noſtrils; but it is not ſo in the natural State of Things, with Reſpect to the Matter which fouls the Inſide of the Hollows ſituated at the Sides of the Partitions of the Noſe; for we have ſhewn already that they are ſo deep and crooked, that there is no Way of getting any thing once lodged there, out of their Bottoms, by the natural Paſſages.

This incurs the Neceſſity of another Opening in the Bone, to be made by Art, but as this muſt be much lower than the other, there can be no Danger in the making it. All below the Eyes in a Horſe's Head ſhould be conſidered as the Bone of the Noſe, not the Skull; we underſtand by Skull the bony Covering of the Brain, and there is no Brain within or near that Part.

Thus the Farmer ſees that an Opening in this Place is altogether neceſſary, and not at all dangerous. It would be in vain to waſh off the Matter in theſe Cavities ever ſo clean, if, when that were done, a Part of it muſt of Neceſſity be left in the Cavity, together with ſome of the Liquor of the Syringe; but this is eaſily to be diſcharged in this Manner.

Upon this Conſideration, the very beſt Place for making this Opening to waſh and clean theſe Cavities, is to pierce through the bony Diviſions; and then to open another Hole ſomewhat lower, to give Paſſage for all that is waſh'd out.

The beſt Direction for the exact Place of theſe Holes is, that the Farmer and the Farrier together examine the Skull of a dead Horſe. They will there ſee how theſe ſeveral Cavities are placed, and by that know better than by any formal Directions of Words or Figures, where to make them.

When theſe Holes are opened, and the Syringe is uſed, the proper Method is to throw in the Liquor forcibly; and then to ſtop the Noſtril, that it may be forced out at this Hole, by which Means all will be perfectly cleared; and by a Repetition of this cleanſing, and an Injection of proper Liquors, the Diſeaſe will be perfectly and thoroughly cured. This reduces the Glanders to the Condition of an outward Malady, and it is thus to be remedied in the ſame Manner.

In Caſe of the Matter, together with the Injection, not coming freely and perfectly out at the lower Opening, nothing more is needful than to make Way for it by thruſting in the Point of any ſharp Iron Inſtrument. It frequently happens that the Bones have a particular Conſtruction in this Part; but when they have it is attended with no farther Difficulty. This Conformation may ſtop in the Matter, or a Part of it, and the Opening thus made never fails to diſcharge it. If the Opening made by the Point of the Inſtrument, ſhould cloſe up before the Time, it may be kept open by burning it with a red hot Iron.

This Method of Cure was propoſed in FRANCE, and there very well received; and there is no Queſtion of its Succeſs wherever it ſhall be introduced. We have ſhewn the whole Deſign and Nature of the Operation, and ſhall in the next Chapter treat of the beſt Methods of preparing the needful Liquors for injecting.

CHAP.

CHAP. VI.

Of the Liquors to be injected for a Cure of the Glanders.

WE have now to lay before the Farmer the moſt proper Liquors for performing the Cure, and theſe we ſhall adviſe to be of three Kinds; the firſt cleanſing alone, the ſecond cleanſing and healing, and the third Spirituous and Styptick.

For the firſt Liquor let him proceed thus, ſet on three Gallons of Water to boil, and have ready three Pounds of fine Stone Lime new made. When the Water boils pour it into a Pan, large enough to hold three Times the Quantity, and by Degrees put in the Lime. There will be a great ſwelling and boiling up, and when all is over, and the whole thoroughly cold, the Water will ſwim clear and tranſparent at the Top, and the Lime will be ſettled in a white Powder at the Bottom.

Pour off this clean Liquor, and ſet it by all Night; then in the Morning there will be a Skin upon it; ſcum this off and bottle up the clear Water. This is Lime Water of an exact Degree of Strength for the intended Purpoſe. Let the Farmer be ſure not to buy it, but to make it himſelf in this Manner.

To a Quart of this Lime Water put a Quarter of a Pint of Vinegar, and half an Ounce of Baſket Salt, let it all melt together, and then it will be fit for Uſe.

Two Openings being made in the Head of the Horſe, let a Pewter Syringe be got, that has a good Strength to throw the Liquor out, and that will hold about half a Pint.

Set on this Quantity of the Liquor juſt named, to warm; and when it is of ſuch Heat that the Hand can be bore in it ever ſo long without Pain, it is fit for Uſe. Hold the Noſtrils of the Horſe together, and drive in this Liquor carefully and forcibly. It will run out partly at the lower Hole, and partly at the Noſtrils, when they are let open; as they ſhould be at a proper Time, when the greateſt Part of the Liquor has gone the other Way.

When this Syringefull has been uſed in this Manner, heat as much more, and throw it up in the like Way. Then let the Horſe reſt twelve Hours, after which repeat the ſame Method exactly.

Morning and Night are the beſt Times of doing it; and this is to be continued four Days, but with the Uſe of the ſecond Liquor in the Middle, and at the End of that Time.

The ſecond Liquor is thus prepared. Set a Fire Shovel over a very gentle Fire, and put into it a quarter of an Ounce of green Copperas beat to Powder: ſtir it about till it becomes a dry grey Duſt. Put this into two Quarts of Molaſſes Spirit; and add a little Scrapings of Oak Galls. Shake this up and ſet it by all Night. In the Morning it will be black like Ink, and this is a cheap and eaſy Way of preparing the famous Styptick of HELVETIUS.

Upon the ſecond Day uſe the Water with the Syringe, at Four o'Clock in the Afternoon, inſtead of late in the Evening; and, towards Night, warm half a Pint of this black Tincture.

Throw this up with the Syringe in the ſame Manner as the other; and leave the Horſe to his Reſt.

The ſame do on the Evening of the fourth Day, and then prepare the third Liquor.

Powder a Quarter of a Pound of Alum, and add to it the ſame Quantity of white Vitriol. Put them into a ſtrong Earthen Pipkin, without any Water, and ſet them over the Fire; they will melt and afterwards dry again.

Then take them off, grind the Whole to Powder, and put it into a large Jar: pour upon it a Gallon of the Lime-Water juſt directed to be made, ſtir them well together with a Stick, and leave them all Night.

In the Morning pour off the clear Liquor, leaving the Settlement behind; add to it a Quart of ſtrong Vinegar, and bottle it for Uſe.

This is to be the Liquor for injecting, after the four firſt Days.

Every Morning and Evening warm a Pint of this, and carefully throw it up by the Syringe, obſerving to ſtop the Noſtrils at firſt, that the greateſt Part of the Liquor may each Time run out through the lower Hole in the Face: then let ſome of it come laſt of all through the Noſtrils; by this Means, every Part of the affected Skin will be waſhed and cleanſed twice a Day by this excellent Liquor; and, by Degrees, the Whole will heal.

Every other Day, inſtead of Evening, the laſt Injection of the Water muſt be performed in the Afternoon, as directed in the preceding Article; and at Night of each of thoſe Days, the Black Tincture is to be injected, as directed before.

This is a plain, rational, and ſafe Method of Proceeding; and by this Means the Glanders will be perfectly cured, at a very ſmall Expence, and with no great Trouble. Many ſerviceable Horſes will be preſerved from the Dogs, or from the meaneſt Employments, and rendered as valuable as if the Diſeaſe had never attacked them.

As to the Time required to perfect a Cure, it will be different, according to the Degree of the Diſorder; but, in general, it may be called three Weeks or a Month; the Progreſs of the Cure will be ſeen by the Stoppage of the Running; and it will always be adviſeable to continue the Injections a Fortnight after the Cure ſeems perfect, every other or every third Day.

If the Fleſh grow faſt about the Openings, it muſt be kept down by a hot Iron; for there muſt be preſerved all the Time a free Paſſage for the Liquor both in and out; and if the Horſe be otherwiſe diſordered, Brimſtone and Antimony are to be mixed and ſprinkled over his Provender.

CHAP. VII.

Of Purging a Horſe.

THERE are a great Variety of Occaſions on which this Creature may want purging, and many Sorts of Phyſic may anſwer the Purpoſe; but before we come to the Method of preparing any of theſe, it will be neceſſary to give the Farmer proper Directions concerning the Uſe of ſuch Medicines. A Horſe muſt be prepared for a Purge the Day before it is given him, or it will take very little Effect; and then it will operate more or leſs, according to the Management of him during the Time.

The Day before a Horſe is to be purged, give him a good Quantity of Water with ſcalded Bran in it, and let him have it warm. Keep him quiet, and the next Morning, before he has any thing to eat, give him the Purge. Any one of the following will anſwer the common Purpoſes, with little Charge.

1. *A Purge with Aloes.*

Take an Ounce and a Quarter of Horſe-Aloes beaten to Powder, and a Quarter of an Ounce of Cream of Tartar, mix theſe up with an Ounce and a half of freſh Butter, and half an Ounce of Powder of Anniſeeds, work this up into a Conſiſtence, and roll it round into two Balls. Rub theſe over with Butter, and give them to the Horſe; they will, by Means of being greaſed, ſlip down very freely; and after them give him a Horn of ſmall Beer made warm.

The Doſe is to be made larger or ſmaller, as the Horſe is larger and coarſer fed, or finer limb'd, and managed more delicately. There is as much Difference between the Conſtitution of a Cart-Horſe and a Racer, as between a Drayman and a Perſon of Quality; and they muſt in all Reſpects be treated accordingly, not only in the Strength of the Doſe, but in the Management afterwards: for what ſuits one will be quite improper for the other.

2. *A Purge with Jalap.*

Take Powder of Aloes an Ounce, Powder of Jalap a Quarter of an Ounce, and powdered Ginger a Dram: mix all theſe up with two Ounces of freſh Butter, and make the Whole into a Couple of Balls, or more; greaſe them on the Outſide, and give them to the Horſe with ſome warm Ale afterwards. Theſe are two common Receipts, but they are often ill proportioned in the Quantities; ſomething of this Kind ſtands under the Name of a Purge for Horſes in moſt Books that treat of theſe Things; but the Quantity of the Anniſeeds is too great, in the common Directions for the firſt; and this will make a Horſe ſick afterwards; and to the other there are commonly added uſeleſs Ingredients. Theſe are approved Proportions, and they will anſwer almoſt every Occaſion there can be for a Horſe's being phyſicked in this Way.

CHAP. VIII.

Of managing a Horſe with his Phyſic.

WE have directed how a Horſe is to be prepared for his Purge, by giving him a proper Drink the Day before: but it is needful we tell the Farmer how he is to conduct him when he has ſwallowed it.

Let the Balls and the Beer be given him early in the Morning, and let him then be rid out gently for a Quarter of an Hour. Then bring him cool in, and let him be ſet up two Hours without Food.

After this Time give him a ſmall Quantity of good Hay, and a Quarter of an Hour after that ſome warm Water.

An Hour after this give him ſome ſcalded Bran. He will purge kindly after this Manner of Management; and after this he ſhould be rid out a little again; then when he is brought in, he ſhould have ſome Bran and Water warm, with but a ſmall Quantity of the Water. Then led him be rid out again; in this Manner a Horſe is to be treated with his Purge, and, in general, it will be eaſy to make it work more or leſs at Pleaſure, by giving him more or leſs Exerciſe, and more or leſs of the Bran and Water.

If the Purge have been too violent, and will not ſtop, the following Aſtringent Drink will always ſtop it.

An Aſtringent Drink.

Boil three Pints of ſtale Beer, and ſome Pieces of Cruſt of brown Bread: to this put an Ounce of Whiting, and a Quarter of an Ounce of Diaſcordium, made without Honey: if this does not ſtop it, in four or five Hours, give the ſame Quantity of Whiting, and double the Quantity of Diaſcordium, in only one Pint of the Beer and Bread. This will make him altogether quiet and eaſy, and he will be in his Body as uſual.

CHAP. IX.

The Care of a Horſe in taking him up from Graſs.

IT is a common Thing, and generally very proper, to purge a Horſe when taken up from Graſs; but this muſt not be done immediately on taking up; he ought to be kept in the Stable a Week; and he ſhould have ſcalded Bran twice before the Purge.

There muſt be a great deal of Care taken of a Horſe, in general, in the taking him up from Graſs, otherwiſe he will fall into Diſorders very difficult to cure. It is much better to prevent them by a timely Care.

He muſt be dry when taken up from the Paſture, otherwiſe he will very likely grow ſcabby.

BARTHOLOMEW-TIDE is the lateſt he ſhould be left out, if of any thing a tender Make; for

after this Time he will have more Cold and leſs Nouriſhment.

The Dews are very nipping after this Seaſon, and the Graſs has loſt its Strength; ſo that partly for Want of Nouriſhment, and partly for the chilling of his Blood, it is much if he eſcape ſome Diſorder. Many a Horſe has been rendered unſerviceable the greateſt Part of the Winter, and been an Expence into the Bargain, from the leaving him out a little too long.

It is a very good Method with a delicate Horſe, to trim him as ſoon as he is taken from Graſs. To this Purpoſe, he is to be led out in a fine warm Day, and when he is trim'd, ſome Soap and a good Quantity of warm Water is to be got ready. He is to be rubbed over with the Soap, taking Care it does not get into his Eyes or Ears, and then waſhed with the warm Water and ſome Flannel-Cloths: this is to be done twice over, and he is then to be led into the Stable, and gently rubbed with a Cloth till perfectly dry.

This Cleaning is very comfortable to the Creature, and at the ſame Time takes off all Sorts of Foulneſs got at Graſs, of which there are many Kinds not to be met with in the Stable. He is then to be kept a Week or more in the Stable, and purged and blooded. This Courſe naturally and perfectly reconciles him to the new Method of living, and he falls into no Diſorder.

CHAP. X.

For a Cold.

THIS is a Diſorder ſo well underſtood, that it cannot be miſtaken, nor does it need any Explanation.

Boil in a Quart of Ale three Ounces of freſh Liquorice-Root, beat very fine into Threads. Strain the Liquor off, preſſing it hard, and add to it three Drams of Elecampane Powder, one Dram of Powder of Anniſeeds, a Quarter of a Pint of Oil, and a Quarter of a Pound of Honey; mix all well, and give it warm. If it does not take Effect the firſt Time, let it be repeated three or four Times, and it ſeldom fails.

Balls for a Cold of long ſtanding.

Put into a large Bowl ſix Pounds of Wheat Meal, mix with it two Ounces of Powder of Aniſeeds, Cummin-ſeed one Ounce, Linſeed three Ounces, Fenugreek-ſeed one Ounce and a half; ſtir theſe well about, then mix half a Pound of Liquorice Powder, and a Quarter of a Pound of Flour of Brimſtone, add theſe to the reſt. Laſtly, add Bay-berries and Juniper-berries, powdered, three Ounces of each, and the ſame Quantity of Powder of Elecampane.

When all are well ſtirred and mixed together, break ſix Eggs, throw away the Whites, beat up the Yolks with two Quarts of Mountain Wine. Add to this a Pound and a half of Honey and a Pint of Sallad Oil. Mix all theſe perfectly well together; then bring in the Powder, and work the Whole to a Paſte. If this ſhould be too ſtiff, a little more Wine muſt be added; and, if too ſoft, ſome Flour muſt be put in, till the Whole be of ſuch a Conſiſtence that it will conveniently roll into Balls.

Theſe are to be made of the Bigneſs of a Hen's Egg, but round. This rolling them up is only for the Convenience of keeping; when they are to be uſed they are to be diſſolved. Two is the proper Quantity for a Doſe, and they are to be melted in the Creature's Water, Morning and Evening, for fifteen Days.

CHAP. XI.

For the Sleeping Evil.

THE Sleeping Evil in Horſes, is the ſame that we call the Lethargy in our own Species, and it will be as fatal to them as it is to ourſelves, if not remedied in Time. The Cauſe is their eating a great Quantity of coarſe Food, and having leſs Work than uſual.

It ſhews itſelf by their being ſluggiſh, and continually ſleeping or dozing: the Remedy is the following Ball.

Pound in a Marble Mortar a Handful of the Plant called Wall-Pepper, or ſharp Stone-Crop; it is a common creeping Plant upon Walls, and bears yellow Flowers. Put to this a very little White Wine, and ſqueeze out the Juice. Grind in a Mortar four Ounces of Elecampane Powder, and one Dram of Powder of Pellitory of SPAIN; add the Juice to theſe, and then put in a Quarter of a Pound of CASTILE Soap, work and beat all well together; and then put in Liquorice Powder by a little at a time, to bring it to a ſoft Paſte. Keep this in a Pot, and every Morning, before he has taken any Food, give him a Piece of it as big as a large Walnut, greaſed. Let him drink Milk and Water, warmed, after it, and keep him ſtirring.

This is a Receipt I have ſeen try'd many Times, and never once found it fail to make a perfect Cure.

CHAP. XII.

For the Gargle.

THIS is a Diſorder that principally affects the Head and Throat of the Horſe, and, if not taken in Time, is very dangerous. It is alſo unfortunate for the Farmer in another Reſpect, for it is contagious; and, from one Horſe will ſpread itſelf through a whole Stable.

It is moſt dangerous in the Autumn of the Year, and generally attends very dry Seaſons, when there being a Scarcity of Water, the Horſes are forced to drink what is foul and bad.

I have alſo known it plainly cauſed by Horſes feeding upon a poor bad Graſs in wet Places; where there generally lies Water over the Ground; but it happens to be dry at theſe Seaſons. Some Horſes are fond of this filthy Food: I have obſerved their Chops all dirted with eating it down to the Stumps; and generally the Gargle has followed.

A Horſe that has the Gargle hangs down his Head and is reſtleſs: he breathes with Difficulty;

culty; his Eyes are gummy, and his Head ſwells; he rattles in the Throat, and he goes weakly and ſtaggering.

As ſoon as the Farmer ſees this Diſorder in a Horſe, let him ſeparate the Creature from the Reſt; and it will be very proper to bleed them all by Way of Prevention.

Then bleeding the ſick Horſe more largely than the others, give him the following Drench.

Set on two Quarts of Ale to boil, and as it heats ſtir in a Dram of Saffron cut ſmall with a Pair of Sciſſars, and Half an Ounce of Philonium Romanùm. Bruiſe two Heads of Garlick and two good Handfuls of Wormwood, preſs out the Juice ſqueezing it very hard, and pour this to the Reſt; let it boil a little, and then ſet it off.

This is for two Doſes; if the Horſe be very bad, he may have one in the Morning and another at Night; and if not ſo violently taken, one at Night only will do, keeping him three Hours without Food before, and giving him nothing after it.

Let this be repeated every Day, or every other Day, according to the Degree of the Diſorder, for four Times, and let him all the while be kept warm, and give him boiled Oats and ground Malt in a Maſh.

CHAP. XIII.

For Roughneſs of the Coat and Swelling of the Heels.

WHEN a Horſe grows rough in a Stable in Spite of the uſual Care, and his Heels ſwell, the following Mixture is to be given him with all his Food.

Take a Pound of Flower of Brimſtone, half a Pound of Turmerick, and a Quarter of a Pound of Crude Antimony in Powder. Sift theſe together; by which Means they will be thoroughly mixed, and ſtrew a little of it over and among all his Victuals.

CHAP. XIV.

For a ravenous Appetite.

THERE is a Diſorder in our own Species which Doctors call a Canine Appetite, that is an Appetite like a Dog, greedy and devouring every thing, with no Advantage to the Body. Horſes are ſubject to the ſame, and they will conſume more than their due Quantity of Food if it be given them, and ſtill be poor and lean. In this Diſorder they ſwallow their Meat without chewing it. It is much more common than is thought; and we adviſe all who are concerned with Horſes to regard it. They may know it by watching the Horſe's Manner of eating, and by obſerving his Stools.

If he ſnatches at every thing, and eats greedily and vaſtly quick, it is a ſuſpicious Circumſtance: and if his Food be ſeen in a Manner entire and unaltered in his Dung, it is a Proof. When Horſes have this ravenous Appetite to a great Degree, their Provender will go through them quite unaltered, and they will grow poor and weak till they are uſeleſs. In this Caſe give him the following Drench.

Mix together a Gallon of Milk and a Quart of Oil: ſtir in as much raw Wheat Flour as will mix in without making it too thick for ſwallowing eaſily. Give him a good Drench of this every Morning before he taſtes any Food, and about half an Hour after offer him ſome Hay. He will not be ſo ravenous, though he has eat nothing: give him a moderate Quantity, and then let him be quiet.

When he has been rode out a little, or worked for ſome Hours, give him ſome more Hay. He will ſnatch at it and be ravenous as uſual; but let him have only a little at a Time, and let him ſee no more. This Way feed him to the Fill by a little at a Time, till he will not eat any more; then ſet a good Quantity before him, but don't let it remain a great while in his Sight.

Repeat this Conduct every Day for a Week, and he will eat like other Horſes. I have ſeen this tried very frequently and ſucceſsfully.

CHAP. XV.

For the Staggers.

THIS is a very terrible Diſeaſe, and has been fatal to many a ſtout Creature.

The principal Cauſe of it is the Careleſſneſs of Servants, in turning a Horſe out to Graſs while he is hot from Travel or Labour. This gives him a violent Cold, which loads his Head with a tough Phlegm.

A Horſe is known to have the Staggers by his tottering, ſtaggering, and going weakly and faintly. His Eyes will be wateriſh, and at firſt he will thruſt his Head into the Litter, and by toſſing it up and down ſhew his great Uneaſineſs: in the more violent State of the Diſeaſe he will beat his Head againſt the Wall in his Agony.

This is a Diſeaſe ſo dangerous, that it ſhould be watched in the beginning; for it is then much eaſier cured than afterwards.

The firſt Thing is to bleed him; and this muſt be largely. If the Diſorder be perceived in Time, a good Bleeding alone is often a Cure. Some adviſe bleeding in the Flank, but it is of no Conſequence from what Part, except in the Head itſelf; which, if the firſt Bleeding do not ſucceed, may be very well done during the Uſe of the other Remedies.

We ſee frequently, that a natural Bleeding at the Noſe carries off Diſorders of the Head in ourſelves almoſt immediately. The Sailors have a Way of bleeding themſelves in violent Headachs between the Griſtles at the End of the Noſe, and they find great Relief from it: and Dr. Dover tried very hard to bring up the Cuſtom of bleeding in the ſame Part more artfully. I have known it tried ſometimes, and always with Succeſs; but neither the Surgeons nor the Patients liked it, ſo it preſently dropped. The Good accruing from this bleeding, though in never ſo ſmall a Quantity, ſhews what may done

done for a Horſe in this terrible Diſorder of the Head the ſame Way: The Country Farriers Method of doing it is a very coarſe one, but I have ſeen it ſucceed well, and great Good ariſe from it.

They ſharpen a tough ſmall Oak Stick, and ſplit it at the End like a Fork. They thruſt this up the Horſes Noſtrils, and ſet them bleeding; and this is very ſucceſsful. It may be done after two Days, if the following Medicines do not take Effect.

Two Hours after the common bleeding give him the following Glyſter. Heat two Quarts of Emetick Wine, and diſſolve in it a quarter of a Pound of Unguentum Populneum: throw up this as a Glyſter and let him reſt.

Mean time prepare the following Medicine: boil together two Ounces of Powder of the Scoria of Liver of Antimony and five Pints of ſtrong Beer. When it has boiled five Minutes take it off the Fire: diſſolve in it a Quarter of a Pound of Butter.

An Hour after the firſt Glyſter has come away give this in the ſame Manner, and then walk him gently out in a warm dry Place. Rub his Legs well with Whiſps of Straw wetted in ſome Water, and feed him with Bran and Bread, and warm Water.

Two Hours after the ſecond Glyſter has come away, diſſolve an Ounce of Venice Treacle in a Pint of White Wine, and give it to him as a Drench: and preſently after give him another Glyſter thus made.

Boil a double Handful of Mallows Roots and all in two Quarts of Spring Water to a Quart; then add to this when ſtrain'd off two Ounces of Sal Polycreſtum, the ſame Quantity of Venice Treacle, and three Quarters of a Pint of Oil: give this warm, and ſet him up for Reſt.

The next Day let one or other of theſe Glyſters be repeated as Occaſion may require; and put into his Ears ſome pounded Rue, black Hellebore Root and Pepper mixed up with Brandy. Sow up his Ears to keep this in, and let it remain there all Day. Give him the following Drink. Boil in two Quarts of Ale two Ounces of Turmerick, and the ſame Quantity of Aniſe Seeds in Powder; add to the ſtrained Liquor a Quarter of a Pint of Brandy, and give it for a Drench.

The Diſorder is a very ſevere one; ſo that it commonly ſoon terminates either in the Death of the Creature, or in his Recovery from the immediate Danger: but ſometimes, though he get ſoon out of Danger, he recovers ſlowly. In this Caſe the Glyſter need not be repeated, but he ſhould continue in a Courſe of the Drench for ſome Time, and be kept carefully warm and well rubbed.

There is alſo a famous Remedy which often aſſiſts the others greatly; or ſometimes ſucceeds by itſelf: it is this.

Dig up a Dock Root and quarter it; cut a Slip of the Thickneſs of Half a Finger, and an Inch long: ſpread a Plaiſter of common Pitch of Half the Breadth of the Palm of the Hand: theſe two Things being in Readineſs, cut a Slit through the Skin to the Bone in the Middle of the Horſe's Forehead: lay in the Piece of Dock-Root, and cover it with the Plaiſter.

If it runs in twelve Hours, the Horſe will be likely to recover; if not at all, the Caſe is deſperate. Theſe Methods have recovered many a Horſe in my own Stable; and I can therefore recommend them from Experience. Indeed I ſhall ſet down here none but ſuch as I have either tried myſelf, or have been told of from the Experience of People of Credit.

CHAP. XVI.

For the Farcy.

THE Farcy is not ſo deſperate or violent a Diſeaſe as the laſt deſcribed; but it is the moſt loathſome that can be conceived: it is a creeping Ulcer, that ſpreads and runs in a moſt offenſive Manner; and is not eaſily remedied when got to any Height.

The firſt Appearance of it is in hard Knobs and Lumps; and theſe ſpread till they over-run the greateſt Part of the Body in this filthy Manner.

It is owing to a diſordered State of the Blood from bad Food and unreaſonable Fatigues; and when a Horſe is in a Condition to receive the Diſeaſe, ſometimes it will be catched by ſtanding near another that has it. Indeed when the Blood is diſpoſed for it, a very little external Injury will bring it on; the ſpurring with a ruſty Spur, the wounding the Mouth with the Bridle, the galling with the Belt, or any other Hurt.

Often a Horſe will itch ſo in ſome Part with the Foulneſs of his Blood, that he will rub till he breaks the Skin, and the Diſorder ſhall begin that Way, and ſpread quickly. The principal Cauſe is what we have named, unreaſonable Fatigues, and Heats and Colds ſuddenly upon them: but we muſt warn the Farmer of one Way of its coming which few are aware of; which is the fattening up a Horſe haſtily, and taking him from a laborious Life to a quiet Stable.

I have ſeen this Error frequently made. A Farmer having a Deſign to part with a Horſe, has taken him up to fatten in a Hurry; and inſtead of anſwering his Purpoſe, has given him this Diſorder.

It is to be cured moſt eaſily when taken in Time; but the Generality of the Country People are ſo unuſed to theſe Conſiderations, that they don't perceive the Diſeaſe till it is at the Height.

I ſaw a Neighbour JAMES BARNES's Horſe in 1738 cured perfectly, when it was taken in Time, in about a Fortnight; and it was done thus. Firſt the Horſe was blooded largely in the Neck; then the whole Body of him was carefully looked over, and ſeveral of the Knobs were found in different Parts, beſide the two or three that were burſt.

A Liquor was thus made to rub them. Take Half a Pound of Wood-Soot, and the ſame Quantity of Soap Lees, boil them up together; put in two Ounces of Allum, and an Ounce of Verdigreaſe, and a little Water, and ſtir all well together; then put in a Dram of Powder of Euphor-

Euphorbium, and four Ounces of Powder of white Hellebore Root: let the whole boil up together, and then pour it into a Jar.

With this the Horſe was rubbed in all the Places where the Diſeaſe appeared; and at the ſame Time a good deal of Flour of Brimſtone was given him in his Food. The Cure was perfected by this Means, and the Diſeaſe never returned.

Another Method is to anoint the Places with Ratſbane mixed up with Butter; and at the ſame Time give him the following Drench. Take a Handful of the inner Bark of the Elder, the ſame Quantity of the inner Bark of the Walnut Tree, and the ſame of Berberry Bark; cut all theſe ſmall, and put them into two Quarts of ſtrong Beer: let them boil a conſiderable Time. Near the End of the boiling throw in a Handful of Wall Pepper ſhred fine. When it has boiled up once or twice with this, ſtrain off the Liquor, preſſing it hard.

Put to the ſtrained Liquor a Quarter of an Ounce of Grains of Paradiſe, and an Ounce of Powder of Turmerick, and give it for one Doſe.

This muſt be repeated every Day as long as the outward Remedy is uſed; and the beſt Management of the Horſe during ſuch a Cure, is to give him moderate Exerciſe and moderate Food: any Extream is equally wrong.

When the Diſeaſe is in its worſt State, the Sores will not give Way to any of theſe Applications. They muſt be burnt with a hot Iron, and then the ſame Courſe followed that has been directed already: for the ſame Remedies that would take no Effect before, will anſwer the Purpoſe after the Effect of the hot Iron.

CHAP. XVII.

Of the Malanders.

THIS is another external Diſorder of a Horſe very painful and troubleſome, and very difficult of Cure; inſomuch that ſome ſay nothing more is to be attempted than to alleviate the Pain; and that it is dangerous to ſtop the Diſtemper.

This is a very unhappy Error; for there is no Degree of the Malanders but may be cured by proper Management; and that with perfect Safety.

This Diſeaſe ſhews itſelf on the fore Legs, upon the inner Part juſt againſt the bending of the Knee.

It is not a Knob or Ulcer like the Farcy, but a hard, dry, flat Scab, of which ſometimes there is only one great one, ſometimes ſeveral ſmaller; and theſe are cracked and chopped upon the Surface, and have ſtiff Hairs like Briſtles growing upon them.

This is the whole of the Diſorder: it ſometimes is very violent and inveterate, ſometimes more ſlight. When it is very bad it makes the Horſe halt; and when leaſt it occaſions him to go ſtiff till warmed with Exerciſe.

The general Cauſe of the Malanders is bad Management. It is the common Diſorder of Horſes kept in a ſlovenly Manner, and much more rarely affects thoſe which are managed more carefully.

Thoſe Horſes are moſt ſubject to it which have moſt Hair upon their Legs; and they are the difficulteſt of Cure.

One eſſential Difference the Farmer is to make in his Conduct, for a Horſe under this Diſorder, which ariſes from this Conſideration, that ſometimes the Malander is only a Soreneſs in the Part, while the Horſe is otherwiſe in Health; ſometimes the Blood is corrupt and bad, and in this Caſe the Diſorder is more violent in its Degree, and more difficult to be cured.

When the Malander is only the Effect of Careleſſneſs, and 'tis upon a Horſe otherwiſe healthful, the Method to be obſerved is this.

Let him be kept to his uſual Work and uſual Food; and let the following Waſh be made for the Part. Set on a Saucepan with three Quarts of Water, put to it half a Pound of Fenugreek Seed bruiſed, and a Pound of freſh Marſhmallow Root cut in Slices. Boil all this till it is like a Jelly, ſtrain it off hot and preſs it hard out, then add to the thick Liquor half a Pound of Opodeldock Ointment. Make ſome of this hot Morning and Night, and dipping Flanels in it, wrap them round the Leg where the Complaint is, as hot as the Hand can bear to touch them. Let this be ſeveral Times repeated; and at the laſt of all, wet ſome of the Ingredients, which muſt be ſaved when the Liquor has been preſſed out, with ſome of the Liquor hot, and lay them upon one Flannel, cover them with another, and wrap the whole round each Leg, tying it round ſo as to keep it on, but not tight.

Let this be done every Day twice, as directed, till the hard Subſtances begin to ſoften; after this once in four and twenty Hours will do; and there will thus be a perfect Cure.

Before the firſt Dreſſing let the Hair be clip'd round about the Place, and the whole Part about the Malanders waſh'd clean with warm Soap Suds. Let this be repeated at Times dureing the Cure; and after it is perfected, let the Legs be kept very clean in this Part, for fear of its returning.

In this Manner a Horſe will be cured very eaſily, and very certainly, that has no Taint in his Blood: but if there be that added to the outward Malady, Care muſt be taken accordingly, by giving inward Medicines at the ſame Time.

When this is the Caſe the Owner will perceive it by his Habit of Body; and by the outward Remedy not taking its deſired and natural Effect, he is then to proceed thus.

Let a Pound of crude Antimony in Powder be mixed with four Pounds of Flowers of Brimſtone; and let ſome of this be ſprinkled among all his Food. This is better in ſuch a Caſe than giving it in Balls or Drenches, for he takes it with his Nouriſhment a little at a Time, and often; and accompanying the Food in its Paſſage through the Inteſtines, its Virtue goes into the Blood, together with the nutritive Part of the Food.

I have heard many who ſhould know ſomething better than the Vulgar, ſay that they would not cure a Horſe of the Malanders if they could, for

for that all that is prudent is to keep him from growing lame with them. They have an old Proverb that has miſled them from Father to Son for many Generations, which is, That cureing the Malanders is ſhutting up the Wolf in the Sheep Cot. But they may be ſure of this, not only in the preſent Caſe, but in all others whatever, that there will be no Danger or Damage in curing any outward Diſorder; when the Blood is at the ſame Time rectified within.

We have ſhewn the Difference already, that when the Complaint is only external, outward Remedies alone may be truſted, but when the Blood is affected inward Things muſt be given to aſſiſt. The Danger even of a Miſtake in theſe Caſes, is not ſo great as theſe Perſons apprehend; for when the Blood is in Fault, and no Care has been taken to amend it in the Cure, the common Conſequence is only, that it breaks out again.

CHAP. XVIII.

For Over-wearineſs.

WHEN a Horſe has been inconſiderately rode or worked; and no right Care taken to recruit Nature by good Food or Reſt, he will be jaded, poor, diſpirited, and ill-looking; and in wrong Hands may be utterly loſt or ſpoiled. In this Caſe he will not eat at all, or not enough; or when he is brought to that his Food will do him little Service. In this Exigence Recourſe muſt be had to Medicines, before he will have any real Benefit from his Provender; and what I have found to anſwer this Purpoſe, better than any other Preparation, is the following Drench. Mix in half a Pint of white Wine half an Ounce of Venice Treacle, and half a Dram of Powder of Saffron; give him this every Night for four Times. It will warm and ſtrengthen Nature in every Part; he will recruit in Strength and Spirit during the Night, and riſing in the Morning from a good Reſt he will eat freely and heartily.

He muſt have choice Food, clean ſoft Water, and gentle Exerciſe, and leſs than a Week will recover him.

CHAP. XIX.

For inward Heat.

IT may always be perceived that a Horſe is out of Order by his own Uneaſineſs. If he be reſtleſs and faint, without any ſeeming Cauſe, and if, upon putting a Hand in his Mouth, his Breath is found to be hot, and his Palate and Tongue inflamed, give him the following.

Mix together a Pint of new Milk; two Ounces of Honey, three Ounces of ſweet Oil, and half a Scruple of Salt Prunella. Give him this every Morning, and keep him an Hour after without Food, repeat it till he is recovered. Three Doſes uſually perfect the Buſineſs, if not he may take more.

CHAP. XX.

For a ſcurfy Skin.

ALL Creatures are liable to Foulneſs of the Skin, when they are not taken good Care of: this is ſometimes attended with other Diſorders, ſometimes not.

When there is no other Complaint joined with it, the Remedies are to be only external. Then proceed as follows.

Make ſome very ſtrong Soap Suds, and put in ſome Vinegar, and ſome Powder of white Hellebore.

Firſt clean the Horſe well dry; then rub him all over with a Bruſh, wet with the Soap Suds, and then waſh him all over with the ſame, by throwing ſome over him, working it in with the Hands and rubbing with a coarſe Cloath.

After this let him be taken in and dried thoroughly, and give him ſome Food and clean Litter.

Mix up a Pound of Flower of Brimſtone, a quarter of a Pint of Oil of Turpentine, and as much Hog's Lard as will make the whole into an Ointment. Rub him well with this an Hour after he is thoroughly dry from the waſhing.

The next Day boil a quarter of a Pound of white Hellebore, and a Pound of Dock Root, in a Gallon and half of Water. Make this into Suds, by beating it up with a good Quantity of Soap, and waſh him with it. Then anoint him well with the ſame Ointment, as before.

Repeat this every Day for ſeven, eight, or nine Days, according to the Nature of the Complaint, and he will be cured: laſt of all waſh him well with the Suds, without anointing him after it.

This is certain to prove a Cure, if there be nothing but the outward Complaint: but when it has proceeded from bad Food, bad Water, and ill Management, as well as Uncleanlineſs, then the ſame outward Method is to be uſed; and he is to have Flower of Brimſtone and Powder of Antimony inwardly, as we ordered in the laſt Receipt.

There is no Need to alter the Medicines when the Deſign is the ſame, and there is no Way ſo good of giving them. All External Foulneſſes are to be cured with Eaſe and Certainty; and in a very little Time in this Manner.

CHAP. XXI.

For ſore Heels.

SET on an Earthen Pipkin, with a Quart of freſh Urine. Put to this an Ounce of Roman Vitriol, and four Ounces of green Copperas, let theſe melt, and then put in the Gall of an Ox, and a quarter of an Ounce of Oil of Vitriol. Rub the ſore Part gently with this every Morning and Night till it is well.

Then waſh it very clean with Soap Suds, and keep it clean from time to time for Fear of a Return.

If there be a great Running from the Part after

after the firſt two Days, put in a quarter of a Pound of Alum to the Liquor.

For a Cold caught at Graſs.

This is not dangerous in itſelf, but ill Management may bring it to be fixed, and to have the worſt Conſequence. Timely Care ſoon remedies it; and the proper Courſe is this. Set on a Pipkin with a Pint of Ale, and half an Ounce of Liquorice Juice, commonly called Spaniſh Liquorice. Stir it about, and when the Liquorice is thoroughly diſſolved take the Horſe up, and give it to him early in the Morning: ride him half an Hour ſoftly after this; and then turn him out.

Repeat this every Day till he is cured, which is generally in a Week.

CHAP. XXII.

For the Cholick.

THE Horſes which are kept with great Care are leſs ſubject to the Cholick than others; but none are exempt from it entirely: it is a very common Complaint in the Farmer's Stable; and when it is not properly managed in Time will frequently be attended with very bad Conſequences.

The moſt uſual Cauſe of this Diſorder is the feeding upon coarſe green Food: let the Farmer therefore, when he perceives this Diſeaſe coming on, change the Food of the Horſe; and give him ſome warm Bran and Water, with a few Drops of Oil of Juniper.

Often this alone proves a perfect Remedy; but when it does not anſwer Expectation let the Farmer loſe no Time, but give him the following Glyſter.

Boil two Handfulls of Mallow Leaves, Stalks, and Roots together in three Quarts of Water, till it comes to two Quarts, then ſtrain it off. Set on the clear Water again, with a quarter of a Pound of Caraway Seeds; and a quarter of a Pound of brown Sugar, let it boil up two or three Times, then ſtrain it off, and add to it a quarter of a Pint of ſweet Oil, and a Spoonful of Oil of Turpentine. Let this be given as a Glyſter and walk him after it.

Two Hours after this is come away give him three Drams of Philonium Romanum, diſſolved in a Pint of warm Water, as a Drench. This very ſeldom fails.

If it does not anſwer by the next Morning repeat the Doſe. Keep him from bad Food, and give him warm Water with ſome Bran to drink, and he will perfectly recover.

CHAP. XXIII.

For the Convulſions in the Bowels.

THIIS is a Name by which the Farriers and others concerned in Horſes expreſs a Degree of the Cholick much worſe than the preceding, and often very dangerous.

The Farmer will know it by theſe Signs. The Horſe ſtretches out his Legs, his Neck, and his Belly at Times; he rubs himſelf againſt the Walls; ſtamps upon the Ground violently with his Feet; and lies down and gets up again many Times together. His Belly looks ſwelled; and in the Beginning of the Diſorder his Mouth is very hot; afterwards it is cold; and then he is in great Danger.

Firſt bleed him moderately; then give him the ſame Glyſter as laſt directed, only adding to it a quarter of a Pint of Gin.

Diſſolve one Dram of Philonium Romanum, in half a Pint of Mountain Wine: add to this a quarter of a Pint of ſweet Oil, and two Tea Spoonfuls of Spirit of Hartſhorn, give him this as a Drench; and ride him or walk him ſoftly after it.

If this does not anſwer in three Hours. Grate a couple of Nutmegs, put them into a quarter of a Pint of Gin: add a quarter of a Pint of ſweet Oil, and one Dram of Powder of Saffron.

Give him this and walk him ſoftly.

If there be no Amendment repeat the Glyſter.

Then give him theſe two Drenches alternately once in four Hours, till he is well. I have ſeen more than one Horſe loſt by this Diſeaſe for want of Care, but never knew this fail.

CHAP. XXIV.

For Cracks about the Feet.

WHEN this Diſorder is taken in the Beginning, it may be very well cured by the Method we have already directed for the Cure of ſore Heels; but when it comes to an inveterate Height, and the Cracks are deep, and their Edges hard, it is to be treated in a different Manner, and great Care muſt be taken or there will be no ſound Cure.

To this Purpoſe, boil together a good Quantity of Marſhmallow Roots and Bran in ſome Water, and ſtraining this off beat it up to a thick Lather with Soap. Let the Heels all about the Cracks be thoroughly ſoaked and waſhed with this: and then dry them.

Make the following Ointment. Set on an Earthen Pipkin with a quarter of a Pound of Hog's Lard, and the ſame Quantity of Venice Turpentine. When they are melted throw in half an Ounce of Bees-wax ſliced thin, and when that is melted duſt in half an Ounce of powdered Verdigreaſe. Stir it all very well together; and when it is mixed take it from the Fire, and ſtir it now and then till it is cold, that the whole may unite thoroughly.

When the Heels are dry from the waſhing, anoint them very thoroughly and very carefully with this, both on the Edges and within: then ſpread ſome of it upon Leather, and wrap round the Heels. Let this be kept on by tying; and not removed till the next Morning: then let the whole Dreſſing be repeated as at firſt, waſhing, anointing, and covering them up. Let this be repeated every Day, and there will be a ſpeedy Amendment, and in ſome Time a laſting Cure.

CHAP. XXV.

For ſwelled Heels.

THIS is an Accident to which many Horſes are liable that are kept in Stables, when they have no other Complaint whatſoever. Bleeding is ſerviceable, and it is no Way ſo well performed as by Leeches upon the Part.

For this Purpoſe there is no Need of that Trouble that is taken in bleeding our own Species this Way, for Nature will teach the Leeches to do it. In a Morning let the Horſe be led into a Pond that is ſhallow, and has a good many of them in it. Let him be kept ſtanding there ſome little Time, and there will a good many of them faſten on him of themſelves. There let them take their Chance: they will preſently make a good Bleeding, and the Horſe will ſoon recover without any farther Trouble or Concern.

CHAP. XXVI.

For a Strain.

DISSOLVE two Ounces of Caſtile Soap in as much Spirit of Wine as will do to melt it: the Soap muſt be cut into thin Slices, and put into a Jar with the Spirit of Wine, and ſet in a warm Place. When this is diſſolved put in Half an Ounce of Camphire; that will melt preſently, and then the whole will be fit for Uſe: it is a Kind of Opodeldock, and will anſwer all its Purpoſes. Let the ſtrained Part be rubbed with it very well with a warm Hand every Night and Morning, till the Cure is compleated.

CHAP. XXVII.

For running Eyes.

THE Eyes of Horſes are the Seat of many Diſtempers; ſome of them very difficult to be removed, and ſome requiring the manual Operation of the Farrier: but there are others leſs violent, that yet are troubleſome; and may, if not taken into timely Conſideration, grow to Danger: this of Running is one of thoſe, which may always be cured by the timely Uſe of the following Water.

Take four Handfuls of Ground-Ivy, cut it ſmall, and then beat it in a Marble Mortar.

Boil ſix Eggs hard, chop the White to Pieces and put to the Ground-Ivy, then beat them again.

Then put in Half a Pint of Mountain-Wine, and a Quarter of a Pint of Roſe-Water; and add an Ounce and Half of White Vitriol, and the ſame Quantity of White Sugar Candy firſt beat to Powder in another Mortar. Beat all theſe well together, and then put them into an earthen Pan. Strew ſome Baſket Salt, about an Ounce, over them, and covering the Pan ſet it in a Cellar to remain ſix Hours.

Then make a Bag of thin Flannel like a Jelly-Bag, hang it up and ſet a Pan under it. Pour in all that is in the Pan, and there let it remain till the whole Liquor is gone through without ſqueezing.

Put this up in a Bottle, and every Morning and Evening drop ſome of it into the Horſe's Eyes, and rub them gently with it, dipping the End of a ſoft Feather into it for that Purpoſe. In a few Days it will make a Cure.

CHAP. XXVIII.

For a Film growing on the Eyes.

BOIL an Egg hard, ſeparate the Yolk and chop the White to Pieces. Mix with it ſome Baſket Salt, and put it into the Shell of another Egg that can be kept whole, and ſet it over the Fire. Let it ſtand till it will come to a Powder.

Mix this with two Ounces of Honey and three Grains of White Vitriol in Powder. Put this a little at a Time into the Eye with a Feather, and it will often make a perfect Cure.

This muſt be done as ſoon as the Diſeaſe ſhews itſelf; for it is not to be depended upon afterwards.

CHAP. XXIX.

For Cramps.

HORSES are ſubject to Cramps as well as we; and they are very painful. They are diſcovered by the Creature's Uneaſineſs, and by the drawing up of his Limbs: the Cure is this.

Put into a large Bottle a Pint and Half of Vinegar and a Pint of Oil; ſhake them well together; then wet a Woollen Cloth well with them and wrap it round the Limb. If the Cramp do not go off before this is dry, repeat the ſame Thing, wetting the Cloth well again, and it rarely fails to compleat the Cure.

CHAP. XXX.

For the Anticor.

THIS is a Pain in the Breaſt of a Horſe, often very troubleſome, and frequently the Fore-runner of Danger. It riſes from the eating too great a Quantity of rich freſh Food: as when a Horſe has been turned looſe at once into a Clover Field and left to himſelf, or the like: the Cure is this.

Firſt bleed him moderately; and then give him the Aloe Purge we have before directed. If he is not much better let him be blooded again the Day after, and the Purge repeated, as there may be Occaſion, and all the Time let him have moderate wholeſome Diet, and ſome Exerciſe.

This Diſorder in Horſes is very like a Surfeit in our own Species, and is to be cured in the ſame Manner: nothing is required but cooling

and

and opening the Body: and if it be not done the Diſorder will gather Strength, and much worſe will follow.

The Farmer will eaſily know by the Horſe's going, and his Motions of various Kinds, whether he is growing worſe or better after the firſt Doſe and the firſt Bleeding. If he faulter in his Legs, and have a Stiffneſs in his Neck that he can ſcarce bow it down, all is going wrong: if he take frequent Tremblings, it is worſe: the Bleeding muſt then be repeated immediately, and the Purge be given every other Day till he is well. The Quantity of Blood loſt at two, three, or four Bleedings upon ſuch an Occaſion, will never do the Creature any Harm; and the Cure entirely depends on it.

CHAP. XXXI.

For Sickneſs at the Stomach.

THIS Diſorder is uſually owing to a great deal of Provender; or to the eating freſh Meat too careleſsly. I have ſeen a Horſe from an over-feeding upon Clover caſt up all he takes both of Food and Water; and in this Manner he will go on to his Deſtruction, if not timely remedied. The Cure is this.

Make a Quart of Ale hot, and diſſolve in it Half an Ounce of Venice Treacle, a Quarter of an Ounce of Philonium Romanum, and a Dram of powdered Cinnamon. Give him this as a Drench; and if it ſtays upon his Stomach, give him an Hour afterwards a Feeding by Hand of ſmall Bits of Bread, and a very little Lock of Hay between them. This will continue upon his Stomach, and he will recover.

If the Drench did not ſtay upon his Stomach, give him the following. Heat half a Pint of Red Port Wine with a Lump of Sugar: put into a Baſon three Drams of Salt of Wormwood, ſqueeze in four Lemons, and ſtir it about till the Salt is diſſolved: then when the Wine is boiling hot ſtrain this to it, and give it him for a Drench. This will be ſure to ſtay upon his Stomach, if the other does not; and afterwards he is to be fed as before directed.

CHAP. XXXII.

For the Yellows.

THIS is a Diſorder ariſing from an overflowing of the Gall, and it may be called the Jaundice in Horſes; for it ariſes from the ſame Cauſe as that Diſeaſe in our own Species; and is to be cured by the ſame Kind of Medicines.

This Diſorder firſt ſhews itſelf by a Yellowneſs in the Whites of the Horſe's Eyes. Then the Skin of the under Part of his upper Lip next to his fore Teeth is tinged yellow; and then he grows faint and unable to perform his Buſineſs. He will fall down as he is in the Stable, be covered with Sweat as he ſtands ſtill, and often ſhiver.

In this Caſe beat in a Mortar a Hat Crown full of freſh Celandine; add to this four Ounces of Powder of Turmerick and a Pint of White Wine. When all is well beat together preſs out the Juice, and put to it in a large Bottle one Dram of Powder of Saffron, and the clear Juice of four Lemons. Shake all well together.

Bleed the Horſe in the Neck moderately; and an Hour after give him for a Drench a Pint of hot Ale and a Quarter of a Pint of this Mixture. Let the ſame be repeated every Night and Morning till he is perfectly recovered; giving him moderate Exerciſe.

CHAP. XXXIII.

For the ſwelling of the Spleen.

THIS is a Diſorder which renders a Horſe feeble and untractable: he faints in the Stable, loaths his Food at ſome times, and ſnatches at it voraciouſly at others; and he is frequently looking to his left Side, lying down upon it, and rubbing it againſt any thing.

The Remedy for this is to be ſought in the Fields: the Herb Agrimony is a certain Cure: but it muſt be taken for ſome Time. The Diſorder riſes from an Obſtruction in the Spleen, according to its Name; and this Herb is a certain Cure for all Complaints of that Kind.

Gather a good Quantity of this Plant freſh out of the Fields, and cut off the tender Tops. Beat theſe in a Mortar, and add a little Sugar, make them into a Conſerve, and ſet this by.

Then pound the reſt of the Plant, and mix ſome Beer with it by Degrees as it is beating: and when it is all a Maſh preſs out the Juice.

Roll up a Ball of the Conſerve, and rubbing it over with Butter give it to the Horſe in the Manner of a Pill. After it give him Half a Pint of the Juice preſſed out as before directed and made warm.

Let this be repeated every Morning and Night; and give him moderate Food and good Exerciſe. He will not be able to bear the Exerciſe well at firſt, but he will do better daily; and by that it will be ſeen that he is growing well: the Courſe muſt be continued till he is quite recovered; which will be known by his leaving off rubbing and looking at his left Side.

CHAP. XXXIV.

For the Heat of Urine.

THIS is a Diſorder in a Horſe, the ſame with the Strangury in our own Species; but it is to be cured more eaſily if taken in Time. I have obſerved it very often in Autumn, and ſcarce at all any other Seaſon of the Year; and I am convinced it is owing to certain Inſects the Cattle of many Kinds eat at that Time, in cropping the young Shoots of Trees, Shrubs and Hedges.

Every one knows that the taking of the ſmalleſt Quantity of the Drug called Cantharides or

Spaniſh Flies, occaſions a terrible Stoppage and Heat of Urine. Cantharides are a Kind of green Beetles found upon the Buſhes in SPAIN; and we have the very ſame Kind, but ſmaller, in ENGLAND. They live among the young Shoots of Trees at that Seaſon; and now and then are ſwallowed up by the Horſes that crop them: in this Caſe a Heat of Urine comes on, and the Horſe is in terrible Pain: the Part ſwells and inflames, and he is continually wanting to make-water, though he can make only a Drop or two. His Blood is enflamed at the ſame Time; and if due Care be not taken, the Conſequences will be dangerous.

Chop to Pieces four Pounds of the Roots of Fennel, ſix Pounds of the Roots of Mallows, and two Pounds of the Roots of Parſly. Set them on to boil in a Copper with eight Gallons of Water, and put in three Pounds of French Barley. Let them boil heartily together for half an Hour, ſtirring them well about: then when the whole is a little cooled ſtrain off the Liquor, and ſqueeze it hard from the Ingredients.

Give the Horſe equal Quantities of this Liquor and Milk mixed together warm for his Drink; and let him drink as much of it and as often as he will.

The Heat of his Blood will make him thirſty, and the Quantity of this Liquor he ſwallows will ſoon be a Cure.

If the ſame Diſorder happen at any other Time of the Year, and from any other Cauſe, this Medicine will alſo cure it.

CHAP. XXXV.

For Difficulty of Urine.

THIS is a Diſorder the Farmer muſt be careful not to confound with the other; for they ſomewhat reſemble one another; though they have different Cauſes, and require a different Method of Cure.

The former is an Inflammation of the urinary Parts; but this is only an Obſtruction by Gravel.

It is ſeen by the Creature's ſtraining very hard to void his Urine, and often without being able to make any. In this Caſe let the Part be examined; and if there be no Heat or Inflammation, it is a Sign this is the Caſe. Alſo if the Diſeaſe be of more Continuance; and if the Horſe can ſometimes void a great deal. All theſe are Signs it is an Obſtruction, and not an Inflammation; and the Farmer being ſure of this by the Symptoms is to proceed thus.

Let him boil a large Quantity of French Barley in Water, and mix the Liquor with all the Water he drinks; and let him give every Morning the following Drench. Take Juice of Arſmart and Parſley-pert, of each a quarter of a Pint; Sweet Oil ſix Spoonfuls, and Oil of Turpentine half a Spoonful; give it warm, and an Hour after let him drink plentifully.

CHAP. XXXVI.

For bloody Urine.

THIS is a Diſorder that ſhews itſelf very evidently; ſo there can be no Miſtake of its Nature.

It is generally owing to over-working; and this will oftenеſt be the Conſequence, when with a great deal of Work the Creature is fed poorly.

The Remedy is this.

Bruiſe a large Quantity of that wild Craneſbill, which is called Herb Robert: ſqueeze out the Juice, and add to every Pint of it half a Dram of Alum powdered, and two Drams of Dragons Blood. Give half a Pint twice a Day till he is well.

CHAP. XXXVII.

For the Vives.

THIS Diſorder is a Swelling in the Kernels, between the Chop and the Neck of a Horſe. It generally proceeds from Cold; and when it is attended with much Inflammation may be dangerous. The Remedy is this.

Bleed him largely, and pour into his Ears Juice of Rue mixed with a good Quantity of Pepper. Tie the Ears round to keep it in; and if he be not better the next Day repeat the Bleeding, and afterwards give him the common Purge ſet down before.

CHAP. XXXVIII.

For Soreneſs in the Noſtrils.

THIS is a Diſorder that is very troubleſome to Horſes kept at Graſs; and they are found to be moſt ſubject to it which are fed in low wet Grounds. It is to be cured by an outward Application in this Manner.

Bruiſe ſome Plantain and preſs out the Juice. To a Pint of this put a Pint and a Quarter of Vinegar, and two Drams of Alum. Mix all very well together; and firſt waſh the Part clean: then anoint and rub it gently with this Liquor. Repeat this every Day once or twice; and if it do not take ſpeedy Effect put in more of the Alum: according to the Nature of the Diſorder more or leſs will be required; but this is generally ſufficient.

CHAP. XXXIX.

For bleeding at the Noſe.

THIS is an Accident to which Horſes are liable, in the ſame Manner as our own Species; but it is uſually much more violent in them than in us. It is to be treated according to the Degree of it in a different Manner.

If it be very violent the Horſe muſt be immediately blooded in the Flank, and while he is bleeding the following Mixture is to be prepared. Bruiſe in a Mortar equal Quantities of Clown's Allheal, and Wood Betony, add to it a little Salt, a little Allum, and ſome Colcothar of Vitriol; when all is beat together thruſt ſome of it up the Noſtril that bleeds, and keep it firmly to the Place till it is ſtopped.

As there may be Danger of its breaking out again in the Night, there ſhould be a Quantity of the ſame Mixture thruſt up in the Evening, and by Means of a Bandage properly made, it ſhould be kept in.

When the Occaſion is leſs violent the Bleeding may be truſted alone; and when moſt ſlight of all the Herbs pounded without any Addition will anſwer the Purpoſe.

CHAP. XL.

Of Diſorders of the Mouth.

A Horſe is ſubject to various Diſorders of the Mouth, which are known by different Names, and ſome of theſe require the Hand of the Farrier; but the greater Part may be cured by the Farmer himſelf.

The Growth of bad Fleſh over the Gums, which is called the Lmapaſs, is to be remedied by burning with a red hot Iron, and for this the Smith or Farrier is fitteſt, becauſe Practice is the beſt Director. But for thoſe Cracks and Warts in the Palate, and all the little Puſtules and Inflammations to which it is liable, the Remedy is this. Gather a good Quantity of freſh Leaves of Wormwood, ſtamp them and preſs out the Juice, mix an equal Part of this and of Ægyptian Ointment, and ſtir theſe well together; then, with a Piece of Rag tied to the End of the Scuer, rub over the ſeveral Parts that are ſore, and they will be cured in a few Times dreſſing. Swellings under the Tongue, are cured in this Manner.

CHAP. XLI.

For looſe Teeth.

IT ſometimes happens that the Teeth of a Horſe will be ſore, ſo that he cannot chew his Meat, and at Times they will be looſe; theſe are great Inconveniences, and muſt be remedied ſo far as may be, as ſoon as they are perceived. For this Soreneſs in the Teeth uſe the following Waſh.

Gather ſome Leaves of Wood Betony, and boil them in Ale till it be very ſtrong of them: then ſtrain it off, and mix with it an equal Quantity of the ſharpeſt Vinegar. Heat this as hot as can be well borne, and waſh the Gums about the Roots of the Teeth with it every Night and Morning: at the ſame Time feed the Horſe for ſome Days with the ſofteſt Food that may be, and then leave him to his common Life again.

This generally proves a Remedy for Soreneſs of the Gums; but when the Teeth come to be looſe the Caſe is much worſe. In this Situation after the Gums have been well waſhed with the Liquor before directed, bring in ſome freſh Leaves of Elecampane, and rub the Teeth and Gums with them: ſometimes this will take Effect. Let the Horſe be blooded, and let him be fed for ſome Days with ſoft Meat; as boiled Oats, and the like Things: for the not forcing them is a very great Article in the Cure.

CHAP. XLII.

For Foundring.

EVERY one who is at all accuſtomed to Horſes knows this terrible Complaint. The Cauſe of it is commonly hard Service and bad Management; from theſe joined together the Creature gets a Diſorder in the Feet, ſo that he is hardly able to ſtand upon them. He will quake and totter; and will be ſcarce able to keep up in going.

This is the Nature of foundering; and the Farmer ſhould have a particular Care of thoſe Things which occaſion it. The ſetting up a Horſe when very hot in a cold Stable without Litter is one Cauſe. The riding him into ſhallow Water, and letting him ſtand with his Feet under it a conſiderable Time when very hot, is another; and many other careleſs Tricks of the ſame Kind may have a like Effect.

But beſides theſe there are other Accidents that will occaſion it: as the wearing ſtrait Shoes, and travelling a great deal upon very rough and hard Ground.

Sometimes a Horſe is foundered on all his Feet, which commonly happens from the ſtanding in Water when hot, or ſome ſuch Accident; but more uſually he is foundered only on his fore Feet: ſometimes the Foundering is only on the hinder Feet; but this is much leſs common.

When he is foundered on the fore Feet he reſts upon the hinder ones as much as poſſible, and is careful how the fore Feet go to the Ground: and in the ſame Manner, when the hinder Feet are affected, he reſts himſelf almoſt entirely on the fore; not letting them come down hard at any Time. This Complaint is alſo known by his ſeeming weak behind as he goes.

The Method of Cure is this. Let the Horſe be taken to a careful Farrier as can be found, and let the Owner ſtand over him to ſee his Operations. He is to pare away the Hoof gently till he comes to the Quick, and then to bleed the Foot in four or five Places at what they call the Toes. This being done, put into an earthen Pipkin equal Quantities of Tallow and yellow Roſin; let them melt together perfectly: then lay on a Quantity of this upon every Part whence the Blood came.

This done, let hollow Shoes be put on; and let another Pipkin be ſet on with equal Quantities of Tallow and Tar; when theſe are well melted together put in ſome Bran, and ſtir all again. Then make this very hot, and ſtop the Hollows of the Shoes with this.

Let this be repeated every Day for eight Days, during which Time keep him quiet and give him moderate Food.

After

After this bring him to more Exercise by Degrees.

Sometimes this Method will make a Cure, but not always; for there are Stages of this Disorder which nothing can relieve.

CHAP. XLIII.

For Wind-Galls.

WIND-GALLS are a Disorder of the Feet, brought on by travelling long together in hard Ways. They are little soft Swellings containing a Kind of Jelly, and appearing on each Side of the Fetlocks. The Remedy is very short and easy. They must be opened to let out the Matter, and then dressed with a Piece of black Pitch spread upon Leather, by Way of Plaister.

The common Practice is to prick them with a Nail, or some such Thing; and this is directed in those Books which treat of these Complaints: but this is a very injudicious Practice. Let the Farmer in all these Cases follow the Practice of the Surgeons; for the Business to be done is just of the same Nature, and they have best studied how to perform it. When they are called to open a Swelling, they do not perform this by pricking it, or making a small Hole for the Matter to come out; but they cut it with their Lancet all the Length; and sometimes again cross-wise: this lets out all the Matter, and gives the Dressing its full Power. In the same Manner in these Wind-Galls, and all Complaints of the like Nature, let the Farmer open the Swelling from Top to the Bottom; and when the Matter is fully and entirely out then put on the Dressing. In this Case the whole Malady is remedied at once; for the Horse is well by that Time the Plaisters come off, which they will of themselves in a few Days.

I have heard Farmers complain of these Wind-Galls returning again and again after pricking; and in this Case they will disorder the Feet of a Horse at length to his Destruction; but it is all owing to this Method of pricking instead of lancing: in that Case all being cleared there is no Fear of a Return; but when the Swelling is only pricked a Part of the Matter is left behind; the Hole presently fills up, and then there is a fresh Gathering; and this as often as it is discharged in that wrong Manner.

CHAP. XLIV.

Of the Anbury.

THIS is a Kind of Swelling or Pustule, that appears like a bloody Wart upon different Parts of the Body of a Horse, and is owing to Accident, without any Distemperature in the Blood. The Cure is this.

Bruise some Plantain Leaves, and press out their Juice. Mix together three Spoonfuls of this, three of Vinegar, and two of Honey; and stir in half an Ounce of powdered Allum. Burn down the Wart with a red hot Iron, close and even to the Body; and then anoint it with some of this Mixture. Repeat this anointing Night and Morning till it is well, and it will never return.

This is a sure Method when there is no Disorder in the Blood; but as this Distemper is sometimes attended with a bad State of the whole Mass, a further Caution is then necessary. The Farmer may be satisfied nothing more is amiss, if the Anbury is perfectly and soon cured by this [illegible], and does not appear again in other [illegible] and if the Horse appear clean and healthy: [illegible] the Complaint rises in one Place, when it [illegible] cured in another; and especially if at the same Time the Creature be gross, full of foul Humours, and have other Disorders upon the Skin; then there must be Care taken of the whole Mass, as well as of these single Eruptions.

In this Case let the Horse be first blooded; then let the several Anburies be burnt down and dressed in the Manner we have directed, and let there be Flower of Brimstone and crude Antimony in Powder sprinkled amongst all his Food.

During this let the Owner watch the Appearance of others breaking out; and always burn them down as they come. By this Method there will be a perfect and lasting Cure.

CHAP. XLV.

For a general Decay.

SOmetimes a Horse will fall into a general Decay, without any apparent Cause: he will be weak and faint, and his Coat will grow rough, and he will lose his Flesh till he seem dying and irrecoverable. This is to be remedy'd, if taken in Time, by the following Medicine:

Take six Pounds of fine Wheat Flour, mix with it two Ounces of Aniseeds in Powder, and three quarters of an Ounce of Cummin in Seed, also powdered; Seeds of Carthamus powdered, a Dram and half; Fenugreek-Seed an Ounce and half, Flour of Brimstone two Ounces, Powder of Vipers three Ounces, Powder of Saffron one Dram, and Powder of Cochineal a Dram and half.

Mix all these Powders perfectly together, stirring them about; and then put to them a Pint of Sallad Oil, a Pound and half of Honey, and two Quarts of White Wine.

Work all this into a Paste with the Hands, adding a little Flour, if it be too soft, and a little Wine, if it be too hard: when it is well wrought, make it up into Balls of the Bigness of a Man's Fist; and give the Horse one of these every Morning in the Water he is to drink, and the same every Evening.

Let the Water be cold, and if he dislike it, give him no other. When he is thirsty he will take to it; and the getting him once to drink it is all the Difficulty, for he will afterwards like it better than any other. In this Manner he will be perfectly cured in three Weeks; and will recover his best Looks, Flesh and Spirit. Care is to be taken that he be kept, during the Time, upon good Food, and have gentle Exercise, but never to fatigue him; and that he lie clean and dry.

BOOK XIII. SECT. II.

Of COWS and OXEN.

22. *Of the Murrain.*

The INTRODUCTION.

THESE Creatures are not liable to ſo many Diſorders as the Horſe; but there is nothing of greater Importance to the Farmer than a right Knowledge of thoſe to which they are ſubject, and the beſt Methods of curing them. A diſtempered Cow or Ox are worth very little. Moſt of their Diſeaſes, as they are of a more ſimple Nature than thoſe of the Horſe, are eaſier of Cure: but there are ſome which we ſee mock all the Art of Phyſic, and all the Rewards a Government can propoſe for deviſing a Remedy. The fatal Diſorder that has now raged ſo many Years is a terrible Inſtance. No Medicines yet diſcovered are able to cure, nor any Regulations to put a Stop to it.

We have examined this Matter with all the Attention the Nature of ſo weighty an Affair demands; and hope we ſhall be able to propoſe ſomething on that Head worthy the Attention of the Farmer and of the Public. We ſhall begin with Diſeaſes of a leſs terrible kind, that the Huſbandman may be led, by Degrees, to the moſt important and difficult.

CHAP. I.

For the Fever.

THE Farmers find their Cows and Oxen ſubject, like themſelves, to Fevers; and theſe, though they generally will go off kindly by Aſſiſtance, often are of very bad Conſequence when neglected. The moſt common Occaſion of them is a Surfeit, and ſometimes they will ſeize them, as ourſelves are ſeized by Sickneſs, without any viſible Cauſe.

The Signs are theſe: The Creature foams at the Mouth and hangs down the Head; the Eyes look heavy, and the whole Body trembles: and it frequently groans very mournfully and heavily. It is hot and reſtleſs, and does not care for Food, but is continually deſiring to drink. Theſe are the genuine Signs of Fevers in Cattle.

The Farmer muſt take Care that he confound them not with the Symptoms of other Diſeaſes, for this is the general Miſtake. Let him remember, that as theſe are the proper Signs of a Fever, ſo there are no other but theſe that are to be conſidered plainly as ſuch.

Many other Diſorders will have the Symptoms of a Fever joined with thoſe that are peculiar to themſelves; and, in that Caſe, the Farmer is to be upon his Guard accordingly: he muſt firſt diſtinguiſh the Diſeaſe truly, or all Advice and all Knowledge of Remedies will be fruitleſs.

In Cattle, as in ourſelves, many, nay moſt other Diſorders, are attended with a Fever; therefore it is natural that feveriſh Symptoms appear with them: hence let the Farmer, when he ſees theſe Signs here deſcribed, in a Creature of this Kind, firſt examine whether there be not, together with them, ſome belonging to thoſe Diſorders, we ſhall deſcribe in the ſucceeding Pages: if there be, then he is to level his Remedies at the Diſeaſe they indicate; thoſe Signs of a Fever being ſymptomatic: and as the other Diſorder is the real Cauſe of them, when that is removed they will go off.

This is the Conduct he is to obſerve when there are the Signs of a Fever, and thoſe of ſome other Diſeaſe together; but when there are thoſe of a Fever only, that is, thoſe we have here deſcribed, and no other, he will find the following Method of Cure generally ſucceſsful.

Firſt bleed the Creature: and as to the Quantity, that is to be guided not only by the Nature of the Diſorder, but by the Condition of the Body: if it be a very violent Fever, more Blood is to be taken away; if leſs violent, leſs: and if it be an Ox, he may be blooded much more freely than a Milch Cow. A Quart of Blood may be very properly drawn from the former; but it is a general and very wiſe Rule, that there never ſhould be more than a Pint taken from the latter. Though, if the Symptoms encreaſe, the Bleeding may be repeated after four and twenty Hours.

When the Creature has been blooded, ſet it up warm, and give it no Victuals.

Boil, in ſix or eight Gallons of Water, a Baſket-full of Plantain-Leaves and Roots, and half a Dozen Handfuls of Agrimony, ſtrain them off, and let the Creature drink of this, warm, as often as can be.

The next Day give a Quart of Ale, with half an Ounce of Venice Treacle in it; and repeat this once in eight Hours.

Give ſome very freſh Hay, ſprinkled with cold Water, after all this; and, by Degrees, the Beaſt will grow well.

During all the Time of the Illneſs, the Lips muſt be frequently rubbed and cleaned, for they furr up and grow foul with the Heat of the Diſorder; and unleſs this Care be taken, it will not eat or drink.

Let the Creature be kept up till perfectly recovered, and after that let it be taken ſome Care of ſeveral Days.

CHAP. II.

For binding of the Body.

THIS is a Diſtemper to which theſe Cattle are very little liable, for their natural Conſtitution is to be looſe; but, for that Reaſon, when it does happen, it is to no Creature ſo dangerous, nor is there any Diſorder in Cattle that requires ſo critical a Method of Cure.

If any of the common Purges that are uſed for Horſes, be given to Cows and Oxen in this Caſe, they ſeldom fail to bring on a Diſorder in the other Extreme, that is much worſe than the firſt; and the Remedy grows worſe than the Diſeaſe.

I have found from Experience that the following is a ſafe and excellent Medicine.

Take a Quarter of a Pound of coarſe ordinary Manna, this Sort is to be bought for a fourth Part of the Price of the fine Kind, and yet for any Uſe it is better. Melt this in a Pint and a half of Ale, put it into a Bottle, and add to it half a Pint of Sweet Oil, and ſix Ounces of Lenitive Electuary. Shake all very well together, then pour out a Gill and half of it: warm this, and give it every Morning and Night till half the Quantity be taken; and then every Morning only till the Remainder is all taken. This never works as a Purge, but it gently produces the Effect, bringing the Creature's Body to a due State and Condition; and as this is brought on gradually, it is ſure to continue. I never once knew a Relapſe after this Cure.

CHAP. III.

Of Looſeneſſes in general.

THIIS is a Diſorder to which Cows and Oxen are much more liable than the former, the Condition of their Diſcharges naturally tending to it; and it is for that Reaſon difficult of Cure, if not taken in Time. When it firſt comes on, it affects them no other Way than by making the Diſcharge thinner, while it retains its natural Colour: after this it becomes paler and ſharper, giving the Creature great Pain; and after that the Stools grow bloody.

Theſe are the true Stages of the Diſtemper. The Farmer is to regard them carefully, for there is to be a different Courſe of Medicines for each. We ſhall therefore, after this general Account of the Diſorder, conſider it under theſe three particular Heads, delivering the proper Remedies.

CHAP. IV.

For a common Looſeneſs.

BOIL half a Pound of freſh Roots of Biſtort in two Quarts of Water. Strain off the Liquor, and add to it four Ounces of Whiting, and an Ounce of Diaſcordium, made without Honey: give the Creature half a Pint of this, warm'd and well ſhook up, three Times in the four and twenty Hours, till the Complaint ceaſes. Sometimes a ſingle Doſe performs a Cure; but in that Caſe it will be proper to give another Doſe, Morning and Night, for two Days, to prevent a Return.

CHAP. V.

For a Looſeneſs with ſharp Stools.

IF the former Medicine have not ſtopped the Diſorder; or if the Farmer have not obſerved it till it comes to the ſecond Stage, that is, till the Creature's Stools are ſharp and diſcoloured, then the following Remedy is to be uſed.

Bruiſe to a groſs Powder half a Pound of the dry Root of Tormentill, and boil it in two Quarts of Water to a Quart.

Squeeze this off, add to it a Quart of rough Red Wine: add alſo a Quarter of a Pound of Whiting, two Ounces of Diaſcordium without Honey, and one Ounce of Japan Earth. Shake this very well together. Warm it every Time it is given, and let the Cow have half a Pint of it for a Doſe, three Times a Day, till perfectly recovered.

CHAP. VI.

For a Looſeneſs with bloody Stools.

THIS Diſorder ſometimes comes on at once; but more frequently it is the Conſequence of Neglect, or wrong Medicines given for the others; or of the Violence of the Diſorder, which ſometimes will not be conquered by the very beſt.

The natural Courſe of the Diſorder is this: a ſharp Humour falls upon the Bowels, and the Stools are thin and cutting.

After a Time they wear off the ſlimy Coat of the Bowels, and then what comes away is diſcoloured; and after this they wear the very Inſides of the Guts themſelves, and then come

bloody Stools. This is the laſt and worſt Stage of the Diſtemper, and it is very dangerous.

When it has arrived at this Degree, the following Method is to be taken:

Firſt let the Creature be blooded, but not largely; then prepare this Medicine.

Bruiſe to Pieces half a Pound of dry Roots of Tormentill, ſix Ounces of dry Pomegranate-Bark, and two Pounds of the Leaves and Roots of Plantain.

Boil theſe in three Quarts of Water to two. Then put in two Ounces of Cinnamon pounded: let it boil a few Minutes longer, and then take it off.

Set it by to be cold, and then ſtrain it off: add to this three Ounces of Dragon's-Blood, in Powder, and a quarter of an Ounce of Roch-Allum.

Shake all thoroughly together; and when it is to be given, warm the proper Quantity: this is to be about a Gill and half, and it ſhould be given three Times a Day.

CHAP. VII.

For Looſeneſſes with great Heat of Body.

WE have told the Farmer what are the Symptoms of a Fever in theſe Creatures; and he is aware that they may happen with other Diſorders. A Purging is one of thoſe with which they may happen, and in that Caſe it is not to be treated as a Fever alone, neither is the Diſorder to be conſidered only as a Purging: a due Regard is to be had to both; and the following Medicine being founded on Reaſon, and ſupported by repeated Experience, I ſhall earneſtly recommend for this Purpoſe to the Farmer.

Cut into Slices ſix Ounces of the Root of the Herb called Avens, or Herb Bennet. It is not ſold at the Druggiſts nor at the Market, but it is common on Ditch-Banks. The Flower is little and yellow; the Head is a ſmall Burr; and the Root ſmells like Cloves. Let this be boiled in three Quarts of Water to two Quarts, adding, toward the End of the Boiling, an Ounce of fine Cinnamon, and two Ounces of Chips of Logwood, ſuch as is uſed by the Dyers.

Strain off this Liquor, and add to it an Ounce of Powder of Virginian Snake Root, and a Pint of Red Port Wine.

Give the Creature half a Pint, warm, twice in twenty-four Hours.

CHAP. VIII.

For the Obſtruction of the Liver.

THIS is a Diſorder to which Cows and Oxen are very liable; the Farmers are acquainted very well with the Symptoms of it, though not with the Cauſe; it is what they call by the general Name of an inward Sickneſs.

The Signs by which it is known are theſe; an Uneaſineſs ſenſible in all their Actions; and a Lazyneſs or Unwillingneſs to move. To this is to be added a Scurfyneſs, and harſh Dryneſs of their Lips, and a Dryneſs of their Noſes in a Morning.

This laſt is a very ſingular but very certain Symptom.

When theſe Cattle are well, if they be obſerved in a Morning, there is always a Drop of Dew, like a Pearl, hangs upon the Noſe; but when they are ſick it is commonly wanting. No Diſeaſe ſooner takes the Effect of getting off this Mark of Health, but it is not peculiar to this. If the other Symptoms ſhew that the Diſorder is of that Kind, this joins with them to confirm it; but if not, the Cauſe is to be ſought farther. In Caſe of an Obſtruction of the Liver, the Remedy is this:

Take a Pound of great Celandine, dug up with the Roots, cut it all to Pieces, Leaves, Stalks, and Roots together, and put it into a Pot, with two Gallons of Water, let it boil up a few Minutes; then add half a Pound of Madder Root, ten Ounces of Turmeric, and four Ounces of freſh Roots of Fennel. Boil theſe very well, and then ſtrain off the Liquor.

Get a Hat-Crown full of Wood-lice, they are common enough about decay'd Timber, and under Stones. Pound theſe with a Pint of White Wine, and ſqueeze out the Juice, then add this to the ſtrained Liquor.

Shake this up every Time it is to be uſed, and warm half a Pint of it for a Doſe. It ſhould be given every Night and Morning for ten Days. This is the uſual Time required to perform a perfect Cure: it may be ſooner, or it may require a few Days longer; but the Medicine will hardly fail.

CHAP. IX.

Of bloody Urine.

THIS is a Diſorder to which Cows are very liable, and, if not taken Care of in Time, it is a very fatal one. The Method of Cure is this:

Take the Cow into a warm Houſe, where ſhe is to be kept till cured.

Bleed her about three Quarters of a Pint, and then give the following Medicine:

Gather a Baſket-full of that Sort of Cranes-bill, call'd Herb Robert. Stamp it in a Marble Mortar, and preſs out the Juice; give the Cow a Quarter of a Pint of this every Morning and Night, and it generally will perform a Cure in about three Days.

It is a kind of Specific for the Diſorder, and cures with ſurprizing Quickneſs: but there are ſome Caſes in which other Diſorders bring on this bloody Urine, and then this Medicine does not anſwer.

Let it be try'd only ſix or ſeven Doſes, and if that do not ſucceed, have Recourſe to the following.

Boil in a Gallon of Water a great Quantity of the ſame Herb Robert, and as much Shepherd's Purſe. When they have boil'd well half an Hour, put in a good Stick of Cinnamon; and after boiling a few Minutes longer, ſet it off the Fire. Then ſtrain it and ſet it by to cool.

Diſſolve in this two Drams of Sugar of Lead, and add one hundred Drops of Spirit of Vitriol.

Shake all well together, and give the Creature a Gill of it cold every four Hours, till the Cure is perfected.

CHAP. X.

For Running of the Noſe.

THIS Diſeaſe which grows to ſuch a terrible Height in Horſes, under the Name of the Glanders, is very ſlight in Compariſon of that, in theſe Cattle. It proceeds from Cold, and the Running is like that from our own Noſes in a like Caſe; only as they hold their Heads down it is not ſo eaſily cur'd, and it will encreaſe upon them to a miſchievous Diſorder in Time, if not ſtopp'd.

Take the Creature up, and let it be kept warm.

Bleed it about a Pint, and then give the following:

Boil a Pint of Ale, and diſſolve in it half an Ounce of Venice Treacle.

Give it warm, and let it be repeated every Night and Morning.

Give the Creature good Provender while under this Method of Cure; and during the taking of the Medicine uſe the following Application to the Part. Melt ſome freſh Butter; and ſtir in as much Flower of Brimſtone as will make it a thick Ointment. Rub ſome of this all over a Couple of Gooſe Feathers, and warm them a little before the Fire; anoint the Inſide of the Noſtrils carefully, but thoroughly, every Morning and Evening with this, till the Diſorder ceaſes entirely.

CHAP. XI.

For Worms.

COWS and Oxen are ſubject to have Worms bred in their Bowels, and they are greatly diſordered by them; they will prevent their thriving, and make them reſtleſs and untractable. The Remedy is this:

Chop to Pieces ſome Savin-Tops, and Leaves of Bear's-foot, mix with theſe a little Salt of Steel, and work up the Whole into a Sort of Paſte with Butter. Divide this into ſmall Balls, and give one of them every Morning early for a Week or longer; keep the Creature without Meat three Hours after the Medicine, but let her drink as much as ſhe chuſes.

If this Medicine do not ſucceed alone, it muſt be aſſiſted in the following Manner:

Diſſolve half an Ounce of black Soap in a Quart of Sweet-wort, and give this every Morning after the Ball of Savin. In this Manner the Cure will uſually be perfected in a few Days.

CHAP. XII.

Of Worms in the Tail.

BESIDE the Worms that breed within the Bodies of Cattle, there are a very troubleſome and miſchievous Kind that breed and live externally in the Tail.

They torment the Creatures out of their Lives, waſte their Strength and Spirits, and keep them in continual pining. They uſually grow lean; their Backs become weak; when they are lain down they are ſcarce able to get up again, and they have a Faintneſs in their Looks and Motions.

When the Farmer ſees a Cow or Ox in this Condition, let him examine the under Parts of the Tail. He will firſt perceive that the Hair is fallen off; then that there are a multitude of little Sores; and, upon further Examination, he will perceive, that the Tail is almoſt eat aſunder in ſeveral Places at the Joints.

This might ſeem to be a natural ulcerated State of the Tail; but it is, in Reality, owing to a Multitude of eating Worms, which will be found eaſily enough upon looking after them. They are occaſioned by Foulneſs of the Tail, which tempts a particular Kind of Fly to lay its Eggs there; or, according to the common Expreſſion, to blow it.

Theſe Worms are hatched from the Eggs, and they live their Time in the Tail amidſt theſe Sores; after which they drop off, and take their Chance upon the Ground, where, if not trodden to Pieces, they harden outwardly, and after a while, they come out a Fly, like the Parent Animal.

There never want a Succeſſion of theſe Tormentors; for the Condition of the Tail draws more Flies to blow it, like Meat that begins to putrify, and thus the Diſeaſe continually encreaſes.

The Farmer thus underſtanding the Nature and Cauſe of the Diſorder, will know how to guard againſt the Accident to which it is owing. And we ſhall next inform him of the Remedy.

It is only in Summer the Diſorder takes its Riſe; though, when once eſtabliſhed, it will continue at all Seaſons.

Therefore as Precaution is in all theſe Caſes eaſier and better than a Cure, let him take Care in Time. We have told him that it is Foulneſs on the under Part of the Tail in Cows, that firſt brings the Flies to them. Nature has ſo diſpos'd the Tail in this Creature, that it is very liable to be made foul. This is an Inconvenience, but it is attended with many Advantages; it is therefore the Buſineſs of the Farmer to remedy the Diſadvantage, which is eaſy, that the Creature, and himſelf in Conſequence, may reap the Benefit.

The Dung of the Cow and her Urine, will be apt to hang upon this under Side of the Tail; and after Calving, there will be alſo greater Inconveniences of the ſame Kind: therefore let a Perſon be employed, once in three or four Days, to clean the Tails of the Milch Cows,

in

in particular in this Part, which will be very eaſy; and of the Oxen, as there may be Occaſion. This will be very agreeable to the Creatures, and were there no other Advantage it would be worth while for this, becauſe the more comfortable they are kept the better they thrive. But if this Care be taken there will be no ſuch Thing as the Tail Worm known. Cleanlineſs will not only prevent the Diſorder, but in the firſt Stages will cure it. The beſt Waſhing is performed by Means of a Bruſh and Soap Suds, and if a few of the Worms ſhould be bred, this will perfectly deſtroy them. We ſhall hope the Farmer will take this Care, and he will need no farther Information; but as a Neglect of this may have happened, or the Diſorder may have ſome Way got footing where he little expects, we ſhall here deliver alſo the Remedy.

Chuſe out a Pound and half of fine freſh and new made Stone Lime. Boil a Gallon of Water, and pour it all at once upon the Lime in a very large Earthen Pan.

It will bubble up in a ſurpriſing Manner. Stir it well togther, cover it up when cold, and let it ſtand all Night to ſettle; there will be a very ſtrong Lime Water, though but a ſmall Quantity of it. In the Morning let it be poured clear off, and kept for Uſe.

Take up the Cows that have the Diſorder, and keep them dry and carefully while they are under Cure.

Make a very ſtrong Lather of Soap Suds in ſoft Water; and firſt of all with Flannels, and afterwards with a Bruſh wetted in theſe Suds, waſh the Tails in every Part perfectly clean; and the more to promote the perfect cleaning of them, cut off the Hair that remains as ſhort as can be.

After the Tails have been thus cleaned and are dry, waſh them in the ſame Manner with this ſtrong Lime Water. Obſerve after four or five Days, whether the Diſorder be cured; if not farther Methods muſt be taken. Once a Day will be enough to dreſs the Tails by theſe two Waſhings, but it muſt be every Time done in this careful Manner, firſt by the Soap Suds, and afterwards by the Lime Water. If theſe fail the following Method is to be uſed.

Stamp a good Quantity of the freſh Tops of Rue and Savin; when they are reduced to a Paſte; add a little white Hellebore and Stone Ocre, both in Powder, and ſome Wood Soot and a little Salt. Beat all this up again, and then mix in ſome Butter. When this is ready, and the Tail perfectly cleaned, let it be ſlit along all the Way down the Inſide, nearly to the Bone, and very thoroughly anointed with this.

If this does not cure in three or four Times, let the Tail be rub'd with a ſmall Quantity of the common blue Ointment, made of Quickſilver, Venice Turpentine, and Hog's Lard.

Theſe ſeveral Methods are to be tried one after another; uſually the firſt ſucceeds, if not, the ſecond rarely fails; but if none will do, the laſt Reſource is to cut off the Tail. But it is beſt to fatten up the Beaſt after this for Sale directly.

CHAP. XIII.

For Boils on the Fleſh.

COWS are ſubject ſometimes naturally to large and painful Boils; and ſometimes they fall into the ſame Misfortune in a ſurpriſing Manner, by Means of a Fly, as in the former Inſtance.

We ſhall conſider theſe Caſes ſeparately.

When a Boil comes naturally on a Cow or Ox, the Thickneſs of the Skin, and the cold Conſtitution of the Animal make them ripen ſlowly, and they alſo heal ſlowly and difficultly afterwards. Nature is, in theſe Caſes, to be aſſiſted in the following Manner. For the ripening of a Boil: take up ſome white Lilly Roots, and boil them in Milk and Water till they are perfectly ſoft. Then lay them hot upon the Boil. Bind them on if that can be done conveniently, if not let a Perſon hold them on till they are cold.

This is to be repeated as Occaſion requires; the oftener the better; and the Boil will ripen and come to a Head.

The opening of a Boil when it is in this proper Condition, may be done either by a Knife, or a red hot Iron, and the general Practice is by the latter Method.

When the Matter is diſcharged, which ſhould be promoted by a Perſon's preſſing it gently, let it be dreſſed with the following Ointment. Put into an Earthen Pipkin half a Pound of Tar, and three quarters of a Pound of Horſe Turpentine; ſet it on a gentle Fire, and as it melts throw in a little Hog's Lard, about two Ounces will be ſufficient. Stir all well together, and dreſs the Part every Day with ſome of this warm, till it is healed.

The other Accident of Boils occaſioned by Flies, is much more wonderful than any thing relating to this Creature, and the Diſcovery of it was made by Mr. De Reaumur, of the Royal Academy of Sciences at Paris, and is delivered in the fourth Volume of his Memoirs, very much at large. The very ſame Thing happens in England, and what we ſee verifies his Accounts.

There is a large Fly that in Autumn teazes the Cattle prodigiouſly. It ſettles upon them, and lays its Eggs in a ſmall Wound, that it makes for that Purpoſe in the Skin. Theſe Eggs hatch in Time, and the Part ſwells with the Hurt. A Cow ſhall thus be covered with filthy Boils, while its Blood is in a perfect good State, and this Accident the only Cauſe of it. There is a Maggot in every one of theſe Boils, which feeds upon the Matter bred there till it is of full Growth, and then crawls out and takes its Chance for appearing in the Fly State, as we have ſhewn of the other.

There is no Need to ſuffer the Creature to be tormented in that Manner till the Maggot goes out of itſelf; but the Aſſiſtance of a careful Hand ſhould be given to clear her of them at once.

Every one of theſe Boils or Lumps ſhould be opened

opened with a ſharp Knife; and the Maggot taken out and deſtroyed. The Wound is then to be dreſſed once or twice with the Ointment before directed, and the Creature will be perfectly freed from the Torment.

CHAP. XIV.

For Diſorders of the Lungs.

THESE are of various Kinds in the Cow and Ox Kinds, as in ourſelves, but Experience ſhews that one Remedy will ſerve for them all. Sometimes the Creature breathes with Difficulty, ſometimes coughs and wheezes; and in either Caſe, or any other proceeding from the Lungs, give the following Medicine. Bruiſe four Heads of Garlick, and preſs out the Juice, mix this with a Quart of new Milk, and add a quarter of a Pint of Tar. This will ſerve for four Doſes. One is to be given every Morning till the Cure is compleated. About four Doſes uſually anſwer the Purpoſe, but if more is required, the ſame Quantity is to be mixed up over again. The Tar does not mingle well with the reſt, but theſe are not very nice Creatures, ſo it goes down.

If the Diſorder be obſtinate, and do not readily give Way to the Remedies, the Creature ſhould be blooded, and they will then take Effect.

CHAP. XV.

For Foulneſſes of the Skin.

CATTLE of this Species are cleanlier in their Hides than moſt others, but they are not altogether free from Blotches, Scurf, and Scales.

When theſe appear they muſt inſtantly be taken Care of, for the Beaſt can never thrive that has them.

Firſt of all let the Cauſe be conſidered, which is often only want of Cleanlineſs, ſometimes a Diſorder in the Blood; and in ſome Caſes it is owing to both together.

Foulneſs of Diet is the common Cauſe of this Diſorder in the Blood; and this is uſually occaſioned by that Sort of rank Graſs which grows in wet Places, and the Weeds among it.

Therefore to undertake the Cure rationally let the firſt Thing be a Change of Paſture. From a low Ground full of rank Weeds, and abounding with Mud, remove the Cattle to a high dry Piece of Paſture, where the Graſs is very ſweet, and the Soil gravelly or otherwiſe dry, ſo that there can be no Dirt for them.

If the Diſorder be only owing to Uncleanlineſs, this Change alone will cure the Cattle.

If the Blood be concerned, this is alſo a very proper Method of aſſiſting the Effect of Medicines.

Let the Creatures be blooded: about a Pint and half from the Ox, and half that Quantity from the Cow.

Then let them be taken in and perfectly cleaned. Warm Soap Suds, a ſoft Bruſh and Flannels are the proper Remedies for this Foulneſs, or they are the needful Preparations for others.

When the Cattle have been perfectly cleaned, if any Scales remain let them be picked off; and the next Day let the Waſhing be repeated. This, and the Cleanneſs of the Paſture, will fully anſwer this firſt Purpoſe.

The next Day let the Creature be waſhed well over with the Lime Water, directed to be made in a former Chapter; and if any of the Scabs have grown to a Bigneſs ſince they were pick'd off, they muſt be rub'd again, that the Lime Water may get to the Root of the Diſorder.

Let this be repeated three Times, at two Days Diſtance; and all the while let there be ſome Flower of Brimſtone ſprinkled among the Hay that is given them in a Morning. In this Manner their Blood will be ſweetened, at the ſame Time that the outward Remedies perfectly cure the Diſorder.

CHAP. XVI.

Of falling of the Palate.

THIS is a Diſorder that frequently ſeizes upon Cattle after hard Labour and Colds, and is of a very troubleſome Nature, if not provided againſt in Time.

When the Palate is firſt fallen it is not difficult to replace, and keep it up; but when it has been any Time down the Difficulty of putting it up, and the Readineſs to fall again, are very great. I have known an Ox obliged to be killed when it was not intended, nor was he fit, becauſe he would otherwiſe have been ſtarved by the unconquerable Continuance and Relapſes into this Diſorder.

The Farmer will perceive that the Creature has this Diſorder by his great Uneaſineſs, and a particular Kind of hollow Groaning: he will be continually ſtriving to eat, but not able to ſwallow, and thus without Care he would go on till entirely ſtarved.

The Remedy is this; caſt the Creature, and getting the Hand into his Mouth replace the Palate as it ſhould be: then rub over it ſome Honey and Pepper mixed together, and let him riſe again: half an Hour afterwards bleed him a Pint and half or more; and thus the Complaint is commonly to be cured without any Danger of a Relapſe.

He muſt not be fed with Hay, but for ſome Days only with freſh ſweet Graſs.

CHAP. XVII.

Of Hurts in the Feet.

WHEN a Cow or Ox is obſerved to limp, and keep one or more of his Feet from the Ground as much as he can, the Occaſion uſually is ſome Complaint about the Hoof, and nothing ſo common as a Soreneſs between the Cloves.

For this the Remedy is eaſy.

Caſt him, and clean the Space between the Cloves perfectly well, rubbing it till it bleeds. In the ſame Manner clean all about the Foot.

Then chop a Quantity of the Leaves and Tops of Mugwort, boil them ſoft in Milk and Water, and put ſome in between the Cloves, and ſome about the whole Hoof, tie it on and let the Creature be kept quiet: the Cure is generally compleated at one Dreſſing.

Some accidental Foulneſs is oftener the Cauſe of this Complaint than any thing elſe; ſo that cleaning it, and laying on a ſoft healing Cataplaſm in this Manner, is a very natural Remedy.

When the Caſe is worſe, and there are actual Sores between the Hoofs, the beſt Method is to clean them as already directed, and then to dreſs them with a Quantity of Black Baſilicon ſpread all over ſome Tow, and drawn in between the Cloves. This ſhould be repeated every Day till the Cure is perfected.

CHAP. XVIII.

Of the panting Evil.

THIS is a Diſorder that ſhews itſelf in the Creature's Faintneſs and Unwillingneſs to ſtir; in his frequent panting, and as it were ſighing. It renders the Creature weak, and he generally waſtes in Fleſh.

The Remedy is this.

Boil a Quart of Ale and diſſolve in it half an Ounce of Mithridate, and a Scruple of Powder of Saffron.

Give this warm every Morning for four Times; it very rarely fails to make a Cure. The Creature muſt be fed upon dry ſweet Hay, and have his Drink warm during the Cure.

CHAP. XIX.

Of the Yellows.

THIS Diſorder in Cattle is of the ſame Nature with the Jaundice in ourſelves. It is perceived firſt by a Yellowneſs in the Eyes; and in the Lips; and the Creature is always lazy and weak. The Cure is this.

Bruiſe in a Marble Mortar a Baſketful of great Calendine Roots, Leaves and Stalks together: add to this a good Handful of Rue, and then ſqueeze out the Juice.

Mix with this an equal Quantity of Juice of Wood Lice, and give the Beaſt a Gill and half of it every Morning, for about a Week; and afterwards every other Morning for a Week longer. In this Time the Cure is generally compleated, and there is no Danger of a Return of the Complaint.

CHAP. XX.

Of the Gargil.

THIS is a very terrible Diſeaſe, and more difficult of Cure than moſt others.

It is an external Swelling and Inflammation; but the Blood is always concerned; and the Diſorder for that Reaſon ſpreads and defies all outward Remedies.

It appears at firſt in the lower Part of the Dewlap, in Form of a hard inflamed Lump, which ſpreads till it occupies the whole Dewlap, and reaches to the Throat, in which Caſe it is very often fatal.

This is the Diſorder called the Gargil diſtinctly and properly conſidered. It affects the Dewlap and Throat only; and it is the firſt Step toward the moſt dangerous Diſorders; but it is of a diſtinct Nature in itſelf, too often deſtroying the Cattle without encreaſing to any greater Degree of Malignancy than this.

Farmers confound the Terms of Diſeaſes, and Farriers more.

Authors who ſhould write for their Information copy their Miſtakes, and conſequently tell them only what they knew before, confirming them in Error, not leading to Truth.

We are entering now upon a Point of vaſt Importance; and unleſs the firſt Steps be cleared of Perplexity and Confuſion, the reſt will never be underſtood.

The Gargil and Garget are treated by theſe Writers, as well as ſpoken of by Farmers and others, as the ſame Diſorder, but this is the Diſtinction.

The Gargil is a Swelling in the Dewlap and Throat, extending no farther; the Garget is a Swelling of the Head and Eyes, with other external Parts, with Inflammation; and the Murrain is the ſame Swelling and Inflammation, extending itſelf alſo to the Inſide of the Throat, the Stomach, and the Bowels.

This laſt is the Diſtemper now, and of many late Years ſo fatal among the horned Cattle, it becomes the Farmer to underſtand it in all its Progreſs; and if the Phyſicians who have written ſo much about it had deſcended from the Cloſet to the Cow-houſe, they would have found the ſame Facts; and knowing ſomething of the Cauſe, they would have been more likely to have made a proper Judgment as to the Method of Cure.

The State of the three Diſtempers is this. The Gargil can never change to the Garget; and if ever it ſeems to do ſo, it is that the Farmer has obſerved the Throat more than the Head and Eyes, when they have been alſo affected, and the Diſorder has been the Garget all the Time, while he took it for the Gargil.

The Gargil may very naturally, and very frequently does change into the Murrain; but the Murrain may begin of itſelf without it.

That is, a Swelling of the outer Parts of the Head and Neck, which is the Garget, may ſpread inwards, and ſo be converted into a Murrain; or the Inflammation and Swelling may begin in the inner Parts, and then it is moſt dan-

dangerous, becauſe leaſt ſeen; and is moſt infectious becauſe the Breath conveys it to all thoſe which have their Heads near: this is the Murrain appearing in its proper Form; and this is of all the moſt fatal.

The Reader will thus underſtand the ſeveral Stages of the Diſorder among the horned Cattle, and thus perceive what is beſt to be done for preventing the Infection.

Having thus, from the firſt Origin, traced its ſeveral Degrees and Appearances, we ſhall now deliver the Method of Cure for this, which is but a Reſemblance, not an abſolute Degree of it.

As ſoon as the Gargil is perceived let the following Ointment be prepared. Melt together equal Parts of Pitch and Turpentine, and add a ſmall Quantity of Bees Wax. Let this be in Readineſs.

Slit open the Dewlap for three Inches in Length where the Swelling is, and let it bleed freely.

Bruiſe in a Marble Mortar a Handful of the Leaves of the great black Hellebore, and add to them ſome Hog's Lard: beat the whole up, and thruſt in a good Quantity into the Slit. Sow up the Wound to keep in the Ointment, and keep the Creature clean, warm and quiet for two Days.

Then open the Stitches, take out the Remains of the Hellebore, and melt ſome of the Ointment juſt directed to be made: dip a large Pledget of Tow in this, and put it into the Wound hot. Repeat this Dreſſing every Day till the Wound heals.

This generally proves a Remedy for the Gargil, when it is not of a very violent Kind; and when it is, ſcarce any Thing will be found effectual. The Addition of equal Parts of Gum Elemi and a few Grains of Euphorbium to the Ointment, is the beſt that can be done.

Let the Farmer firſt take Care that he diſtinguiſhes that it is really the Gargil, and nothing more that ails the Beaſt; and then he will need to do no more than this.

CHAP. XXI.

Of the Garget.

THE Garget commonly confounded with the former in Name, as the Words much reſemble one another, is in Effect a quite different Diſeaſe. It is as we have obſerved in itſelf very terrible; and it is the firſt Stage often of that dreadful Diſeaſe, under which our Cattle now ſuffer.

The Garget is a Diſorder of the outward Parts of the Head, which is attended with Swelling and Inflammation; which frequently ſpreads into the Mouth, and ſometimes into the Throat and down to the Inteſtines. In this laſt Caſe it is properly the Murrain, though it begun with the Garget.

It is very eſſential to treat of theſe diſtinctly, for the Remedies are different; and the proper Diſtinction is this: the *Garget* is *the ſwelling of the Head, Eyes and Lips, extending itſelf to the Gums and Tongue, but no farther*: when it goes farther it acquires another Name.

The moſt uſual Cauſe of the Garget is *bad Water*; but the extreme Degree of it and of the Murrain often ariſe from an infectious State of the Air; and it would be vain to ſeek their Origin elſewhere.

When the Farmer ſees an Ox or Cow affected in this Manner, with a Swelling in the Head diſcovering itſelf about the Eyes, the firſt Thing he is to do is to examine the Lips; and if they are ſwelled, he muſt look into the Mouth and examine the Tongue.

He muſt be careful in his Obſervations, becauſe upon the Difference in this Reſpect depends the Method of Cure which is peculiar in each Degree of this terrible Diſtemper.

If the Eyes, Lips, and whole Outſide of the Head be affected, and nothing more, the Remedy is to be as follows.

Firſt let the Creature be blooded very largely; and immediately after give the following Mixture.

Heat a Quart of Ale, and diſſolve in it three quarters of an Ounce of Mithridate; add ten Grains of Saffron, and a Tea Spoonful of ſweet Spirit of Nitre: give this every ſix Hours, and obſerve whether the Swelling about the Eyes decreaſe; for this is the great Symptom by which to know whether the Medicine takes Effect. Give the Drink warm, and as much as the Creature pleaſes.

If the Swelling continues, eſpecially if it encreaſes, bleed again more largely than before; and inſtead of the Medicine before directed, give three Ounces of Glauber's Salt diſſolved in Water.

This will purge the Creature pretty briſkly; and by this Change of the Remedies there is a fair Chance for a Cure: but we don't pretend to promiſe that Certainty of Succeſs in theſe as in many of the preceding Caſes.

The Diſtemper is of a very deſperate Kind; and there is always Danger. If theſe Methods both fail, the only proper Courſe is to continue them interchangeably, till there is an Amendment or Death. But we have ſeen it in many Inſtances, that the firſt Doſes have been ſucceſsful.

The next Stage in which we are to conſider this Diſeaſe, is that in which the Inſide of the Lips and the Tongue are affected.

This is ſtill the Diſorder diſtinctively called the Garget, provided that the Outſide of the Head be affected alſo; but if otherwiſe it is properly the Murrain, though in a leſs Degree than is uſually underſtood by that Name.

This we have obſerved in various Inſtances: we have ſeen a Murrain, that at firſt appeared leſs terrible than a Garget; but it does not long continue in that Condition: it grows worſe preſently. The Appearance of the Murrain in the Mouth alone is only its firſt Stage, according to the peculiar Manner of taking the Infection.

The Farmer is to conſider and examine this Diſtinction carefully; for thoſe Medicines will be proper in one Caſe, that will be trifling in the other.

Thus then, if he firſt perceive the Outſide of the

the Head ſwell, let him examine within the Mouth, to know whether it have alſo ſpread ſo far: and on the other Hand, if he firſt perceive the Diſorder in the Mouth, let him next examine the Head on the Outſide, to diſtinguiſh whether it be the Garget, or the firſt Stage of the Murrain. We are to ſuppoſe it the firſt of theſe Caſes; and that he finds the Eyes ſtarting, enflamed and ſwelled; the Lips hot and ſwelled; and perhaps the under Part of the Neck, for ſometimes that joins: and he will alſo perceive the Tongue to be very much diſordered. This in the preſent Caſe is a very eſſential Point; for the Tongue is uſually the principal Seat of the Diſtemper.

Let the upper and under Side of the Tongue be ſearched carefully, and probably there will be found one or more Bliſters on the Top or Sides; or a Lodgment of Matter under it; ſometimes both.

Theſe Bliſters muſt be cut, and the Point of a Lancet or fine Knife muſt be thruſt into the ſore or ſwelled Part underneath.

This done, the whole Tongue is to be waſhed ſeveral Times with ſharp Vinegar mixed with Salt, and rubbed with a clean Cloth: by this Means the foul and offenſive Matter will be let out. Then the Creature muſt be kept to the following Courſe of Medicines.

Firſt let him be largely blooded.

Then mix together a Pint of Ale, three quarters of an Ounce of Venice Treacle, a quarter of an Ounce of Anniſeeds in Powder, and two Spoonfuls of the Juice of Rue: this is all to be heated and given at a Doſe; and it muſt be repeated Morning, Noon and Night. Let the Creature be kept warm, and let his Drink be Water, that has been poured hot upon a good Quantity of the Herb Agrimony, and let him have it warm.

I have ſeen thoſe who were impatient with this Courſe, give a Purge in a Day or two, but I never knew it ſucceed. Many have died while it was operating: and on the other Hand ſeveral have recovered by a careful Perſeverance in this Courſe, which have at firſt ſeemed to afford very little Proſpect of it.

CHAP. XXII.

Of the Murrain.

THE Murrain is the higheſt Degree of theſe Diſtempers, and the worſt that can fall upon the Cattle of this Species. What we call the Diſtemper among the horned Cattle at this Time, is the Murrain diſtinctly and properly ſo named. It is an Inflammation of the whole Paſſage through the Body from the Mouth to the fartheſt Extremity of the Guts; and it is attended with a very bad State of the Blood. It ſometimes ariſes from very unfavourable Weather; the drinking bad Water, and being reduced to feed upon rank coarſe Graſs: but the general Origin of it is in the Air, which there is no accounting for. Some Cattle are, by the State of their Blood and Humours at that Time, more expoſed to receive the peſtilential Vapours than others; but all are expoſed to it: and when it has once taken Place, it ſpreads by abſolute and plain Contagion.

This is the Cauſe of its being terribly deſtructive in ſome Counties, and ſcarce appearing at all in others: and to this it is owing, that wherever it gets Footing it ſpreads and continues.

There is no Wonder that Creatures ſtanding near one another receive the Contagion with the Breath, which is ſent out in the Reſpiration from the others; eſpecially as the Temperature of the Air favours the ſpreading.

Upon this Principle we ſee the Wiſdom of the Legiſlature, in forbidding Cattle from infected Places to be brought into Counties where the Diſeaſe is not: and this gives the Farmer the firſt Hint of his proper Conduct.

As ſoon as he perceives this terrible Diſorder upon any one of his Cattle, let him ſeparate that from the reſt, and take Care of all.

The firſt Step is to bleed largely; and this ſhould be extended to the ſick and the well. In Reſpect to the ſick, it is the proper Step to abate the Inflammation; and as to the reſt it may be ſufficient to prevent the breaking out of the Diſeaſe upon ſuch as would otherwiſe have had it, from ſome ſlight Degree of Infection communicated before the Separation of the ſick: or if it do break out upon them, they will have it more favourably.

In another Senſe alſo it is very proper: we ſee that the Air is at theſe Times full of the peſtilential Matter, and that ſome Cattle do and others do not receive it. Thoſe whoſe Blood is in the greateſt State of Inflammation are naturally moſt liable to it; and the Bleeding is a Way of taking off that Condition of the Maſs.

The Cattle that are ſeparated by Way of Preſervation need no farther Care after bleeding; unleſs the Diſeaſe appear upon any of them. In that Caſe ſuch as are taken with it muſt be ſeparated from the reſt; and this is the Manner of treating them.

As ſoon as they have been blooded, let a Quantity of Vinegar be made hot, and a little Salt diſſolved in it; and with that let their Tongues, Mouths, Lips, and Teeth be thoroughly waſhed.

Beat in a Marble Mortar Half a Dozen large Heads of Garlick: preſs out the Juice, and add to it an equal Quantity of Tincture of Myrrh. Set on Half a Pint of Ale to be hot, and put to it a quarter of Pint of this Mixture. When it is all hot together pour in two Spoonfuls of Tar, and then immediately give it to the Creature.

The Tar will not mix with the reſt, but it will go down with them.

Let this be repeated once in four Hours; and if there be no Amendment the firſt Day, let the Creature be blooded again the Day following, and the ſame Courſe continued.

I have ſeen many other Medicines tried, indeed almoſt innumerable; for of all Herbs and Drugs that the old Woman and the Doctor have ever recommended in peſtilential Diſtempers, not one has been omitted on this Occaſion. The Diſeaſe is in itſelf ſo terrible, that it would be Falſhood and Folly to boaſt of vaſt Succeſs

from any: but this we can aſſure the Farmer, whoſe Condition we moſt ſincerely pity when under this Viſitation; that of all the Medicines that have come to our Knowledge this has ſucceeded beſt. Many have been abſolutely recovered by it, when all who ſaw them ſhook their Heads, and ſuppoſed them loſt.

Beſide the great Value of this as a Remedy for the Diſeaſe when it is come on, there is nothing ſo good as a Preſervative againſt it.

For this Reaſon, when ſome Cattle of the Farmers are taken ill, and are ſeparated from the reſt; and when, one after another, ſeveral of thoſe ſet apart fall into it, the whole Number of them ſhould be preſerved if poſſible from the ſame Fate, by taking largely of this Medicine.

The Farmer will not grudge his Trouble when he ſees the Benefit that may ariſe, and when he conſiders the Danger from which he is defending them.

They ſhould all have a Doſe Night and Morning for ten Days after their Separation from the ſick.

The INTRODUCTION.

THESE tho' not ſo numerous as the Diſorders to which the larger Cattle, before treated of, are liable, yet are ſuch as it imports the Farmer as well to underſtand; for they are as fatal as thoſe of the other Cattle, and ſome of them as difficult of Cure, though the greater Part are eaſy. We ſhall explain them ſeverally, according to their Nature; and having eſtabliſhed their Diſtinction according to the Cauſe and Symptoms, ſhall lay down for the Cure ſuch Methods as have been found ſucceſsful, upon repeated Experience, within our own Knowledge.

CHAP. I.

Of the Fever.

THE Farmers know very well what they mean by the Fever in their Cattle, and the Name is not without juſt Reaſon. The Fever in Sheep is an inflamed State of the Blood, diſordering the Eyes and Mouth, ſo that it is eaſily ſeen, and affecting the whole Body of the Creature, though not ſo viſibly.

When theſe Signs of a feveriſh Diſpoſition appear in Sheep, the Farmer muſt feel their Feet; if they are hot, he may be ſure he has gueſs'd right as to the Nature of the Diſtemper; and this is a needful Caution, becauſe there are other Diſorders that will give an inflamed Look to the Eyes and Mouth.

The Diſeaſe is often deſtructive in itſelf; and frequently it brings on other fatal Diſorders.

The Cauſe is generally Cold. When only two or three are affected by it, the Caſe is leſs deſperate; but when many together, it is always the more fatal.

The firſt Thing to be done is to remove the Cauſe; that is, to keep the Sheep in a warmer and more ſheltered Place.

In the Heat of Summer the weaker among the Flock will be ſometimes rendered feveriſh, only by being expoſed too much to it; and in this Caſe the firſt Method is juſt contrary to the former: he muſt drive them to ſhelter: in either Condition they muſt be kept quiet, and muſt have wholſome ſweet Graſs and freſh Water. Then the following Remedies will take place:

Firſt bleed the Sheep that are affected with the Diſorder, and afterwards give to each the following Medicine with a Horn.

Heat a Quart of Ale, and diſſolve in it an Ounce of Mithridate, add half an Ounce of Virginian Snake-Root, and one Dram of Cochineal in Powder. This Quantity ſerves for four Doſes, and one of them is to be given Night and Morning.

If the Sheep be bound in its Body, an Ounce of Lenitive Electuary is to be mixed with each Doſe; but if looſer than ordinary, that is not to be regarded during the Courſe of the Remedies, for it will contribute to the Cure. The four Doſes uſually are ſufficient.

CHAP. II.

For a Purging.

WE have directed the Farmer to leave Nature to her Courſe when a Purging comes on, with a Fever, in Sheep; but when the Fever is abated, the Purging muſt be ſtopp'd; and the ſame Remedy that anſwers for this Purpoſe, may be given in the ſame Manner for ſuch Purgings as come on of themſelves.

Boil a quarter of a Pound of Raſpings of Logwood in two Quarts of Water, till but a Quart is left; when it is near done, put in a Stick of Cinnamon. When it is done, ſtrain it off, and give the Sheep a quarter of a Pint of it, with a Horn, four Times a Day, till the Purging ceaſes.

This ſeldom fails to take Effect very kindly upon that Kind of Purging which was a Symptom of a Fever, though it remains after it is over; but if on other Occaſions it does not ſtay the Diſorder, the following Addition will render it ſure of Succeſs.

To every Doſe of this add a quarter of an Ounce of Diaſcordium without Honey, and ten Grains of Japan Earth powdered; give the Doſes only Morning and Night when they are thus increas'd in Strength.

CHAP. III.

Of the Tag.

THIS though an external Diſorder, yet naturally comes in here, becauſe owing to the Complaint laſt named.

It is a Diſorder of the Tail beginning with Filth and Foulneſs, and ending in Ulceration and very bad Conſequences.

The Tag is ſituated in the inner Part of the Tail: it conſiſts of Scabs and Sores, very painful and waſting to the Creature; and it is owing to the fouling of this Part by a Purging.

That Tag is always worſt which follows a Fever, becauſe the inflamed State of the Blood tends to encreaſe the Diſorder; and when it begins, during the Continuance of the Diſeaſe, the Matter of the Fever may chance to ſettle there. In either Caſe two Things are to be done; the firſt is, to ſtop the Purging, that the Stools may fall as uſual; and the other, to clean the Tail.

The laſt mentioned Remedy, either in its weaker or ſtronger Form, is to be uſed to ſtop the Purging; and the Tail being clipp'd, and the ſore Part laid bare, firſt waſh it carefully with Milk and Water Blood-warm, and then with Lime-water. After this turn the Sheep looſe into a clean dry Paſture.

Two Days after look at it again, and, if not well, repeat the Waſhing, and anoint it with Greaſe and Tar mixed together. Twice doing of this is generally ſufficient for the compleating of a Cure.

CHAP. IV.

Of the Diſorders of the Lungs.

SHEEP are very ſubject to be diſordered in the Lungs, which is eaſily perceived in their Breathing or by their Coughing: nothing requires a more ſpeedy Remedy; for they grow incurable when it is neglected but a little Time; and die as Men in a Conſumption.

Change of Air and Paſture are eſſential to the Cure of this Diſeaſe; without this Caution no Remedies will take Place; with it the following rarely fails.

The Cauſe of this Diſorder, in whatever Form it appears, whether in coughing, wheezing, or panting, in Difficulty or Shortneſs of Breath, is the ſame. It is owing to Cold; and it generally comes upon Sheep that have been kept in low Grounds in wet Weather.

Firſt drive them into an encloſed Paſture where there is ſhort Graſs and a gravelly Soil; and, if poſſible, where there is ſpring or other running Water.

Bruiſe a Baſket-full of the Leaves of Colt's-foot, and preſs out the Juice.

Bruiſe in the ſame Manner an equal Quantity of Plantain, Leaves and Roots together, and preſs out its Juice. Mix theſe, and bruiſe as much Garlick as will yield about a fourth Part as much Juice as one of the others. Mix all together, and add to them a Pound of Honey, an Ounce of powdered Aniſeeeds, and an Ounce and half of powdered Elecampane; give a quarter of a Pint of this, warm, to every Sheep that is affected, once in a Day, and it will by Degrees make a perfect Cure.

Out of a whole Flock thus affected, when the Farmer has taken thorough Care in this Reſpect, I have known when not one Sheep has been loſt. I write this from Experience.

CHAP. V.

Of the Jaundice.

SHEEP are more ſubject than any Animal whatſoever to Obſtructions of the Liver; and this is generally ſeen in a Yellowneſs of the Eyes, and a Tinct of the ſame Kind in the Skin, when carefully examined. Our Farmers, in ſome Places, call this the Choler; or, as they ſpeak it, the Colour: it is properly a Jaundice.

Drive the Sheep that are affected with this Diſorder into an open Paſture; and let the Shepherd or Perſon who has the Care of them, have Orders to keep them often in Motion, but not to fatigue them; then prepare the following Remedy.

Boil in four Gallons of Water two Pound of Fennel Roots, the ſame Quantity of Parſley Roots, and twice that Quantity of Roots of Dog-Graſs, or Couch-Graſs, all cut ſmall; when the Water is very ſtrong of them, and there is about half the Quantity left, ſtrain it off, preſſing it hard.

Bruiſe in a Mortar as much Great Celandine as will yield three Pints of Juice, add this to the Liquor, and laſtly put in three Drams of Salt of Steel.

Mix all well together, and every Day heat ſo much of it as will ſerve to give every one of the Sheep that is ill a Gill and half for a Doſe. This, with the forementioned Directions of good Paſture and Water, and moderate Exerciſe, rarely fails of a Cure.

CHAP. VI.

Of Stoppages in the Throat.

WE have treated of Diſorders of the Lungs, and ſhewn the Remedy; but the Farmer will yet find another Diſorder imitating the Appearance and Symptoms of theſe, which is only in the Throat. The Sheep affected with this, wheaze and breathe with Difficulty. It commonly ariſes from bad Paſturage and Colds. The Remedy is this: Drive them into a higher Ground and keep them warm; then give the following Medicine.

Bruiſe a good Quantity of Penny-royal, and ſqueeze out the Juice. Put to a Quart of this a Pound of Honey, and half a Pint of ſharp Vinegar.

Give the Sheep half a Pint of this, Blood-warm, every Night.

Penny-royal is, by ſome, delivered as a general Remedy for all Diſorders of Sheep; but this is very erroneous: nothing has been hitherto ſo little underſtood as the Medicines proper for Cattle. What are here delivered, are, in general, ſupported by Experience; and that Phyſician who has Judgment to propoſe more Remedies, and Patience to ſee them try'd fairly; to approve and eſtabliſh the beſt, alter and amend the others, and finally to publiſh the Reſult of all, will deſerve a Statue, for the Good done to his Country, more than all her Heroes.

CHAP. VII.

Of Sturdyneſs.

THE Diſorder Farmers call by this Name, is a Kind of Vertigo or Giddineſs in the Head in Sheep. It riſes principally from very rich Feeding, and is often fatal. The Cure is this.

Bleed the Sheep largely, then give the following Draught. Bruiſe ſome Roots of wild Valerian, ſqueeze out the Juice, heat it, and give a quarter of a Pint. Repeat this once in four Hours.

When the Sheep is recovered, turn it upon the Common, or into ſome barren hilly Paſture; it will be kept from Relapſes by having but little Food, and that perfectly wholſome. When this Diſeaſe returns it is commonly fatal.

CHAP. VIII.

Of the Wood Evil.

THE Diſorder Farmers underſtand by this Name is a kind of Cramp: it ſeizes the Legs of Sheep, and will often affect a whole Flock at once.

The Cauſe is cold and wet. The lying under the Drip of Trees in Rainy Seaſons has often occaſioned it, and thence it got the Name of the Wood Evil.

The firſt Care is to remove the Sheep into a dry Paſture, and then the Cauſe being removed, proper Remedies may take Effect upon the Diſeaſe, which would otherwiſe be incurable.

Boil in a large Quantity of Ale as much common Cinquefoil and Hedge Muſtard as can well be ſtir'd into it. When the Liquor is very ſtrong, ſtrain it off, and add a Pint of Juice of Valerian Root to every Gallon of the Decoction.

Give the Sheep that are affected with the Illneſs half a Pint of this, in a Horn, Morning and Night.

Boil in Vinegar a large Quantity of the Leaves of Hedge-Muſtard, and with this Liquor, hot, rub the Legs of the Sheep.

The Trouble of this Method muſt not diſhearten the Farmer from obſerving it punctually, for the whole Flock may be loſt if it be neglected; and when they are once relieved, and in a warmer Paſture, they ſeldom relapſe.

CHAP. IX.

Of the Staggers.

SHEEP have this Diſorder as well as Horſes, and it ariſes from improper Food. They are apt to crop the young Shoots of Trees when in their Reach; and though many of theſe are wholſome, ſome are hurtful. It is found by Experience, that the eating the Oak Leaves and Buds is particularly prejudicial; it binds them in the Bowels, and frequently the Staggers follow.

The Symptoms are much like thoſe of the Sturdyneſs, deſcribed before, but more violent; and there is generally a Trembling, at the ſame Time, of all the Limbs. The Remedy is this.

Diſſolve an Ounce of Aſſafœtida in two Quarts of Water. Give the Sheep a quarter of a Pint of this, warm, every three Hours; it commonly opens their Bowels at the ſame Time that it takes immediate Effect upon the nervous Diſorder, and thus performs a perfect Cure. Some of our Farmers put the Aſſafœtida into the Ears of the Sheep; but that is a very idle Practice. The Medicines are eaſily given them inwardly with a Horn, and there is no other Way in which any Dependance can be placed upon them.

When the Sheep are thus recovered, let them be kept out of the Way of a Return to the ſame Food, and they will be in no Danger of a Relapſe.

The Farmer will ſee by the ſeveral Accounts of theſe moſt ordinary Diſeaſes incident to Sheep, that

that they are not ſo ſubject to them as many other Creatures, from a Variety of unknown Cauſes, but fall into them principally from a bad Method of keeping. In general, low Grounds are the moſt unwholſome; for they abound with wet, and they give Birth to many Weeds of a poiſonous Nature not found in others. And we ſee that Woods are diſadvantageous on many Accounts: therefore let him be careful of his Feeding, and he will have leſs to fear on Account of Diſorders in this Kind; and when they ſo happen, they will be lighter and more eaſily remedy'd.

CHAP. X.

Of the Scab.

THIS is a filthy Diſorder to which Sheep are very liable; but as many of the others, before deſcribed, ariſe oftener from ill Management than any natural Defect, ſo this more than any.

Sheep kept on Downs, or in dry wholſome Paſtures, are very little liable to it; thoſe which lie wet, or get under Droppings of Trees in bad Seaſons, are frequently affected by it in the ſevereſt Manner.

When the Wet falls upon their Skins, and they are heated afterwards; but eſpecially when they lie under Trees and the Wet falls upon them from the Branches, their Skins ſoon after grow ſcurfy, and in a little Time from that there riſe Scabs in various Parts of them; upon this the Wool grows looſe, and the Sheep pine and become lean.

If it be a Seaſon for Shearing, or that can be done with any Degree of Propriety, nothing is ſo good a Step to the Cure: if not, the ſame Remedies muſt be applied without: Cleanlineſs is the great Article for keeping them well; and it is vain to begin a Cure without it.

They muſt be waſhed every where in the foul Places with Soap-ſuds, made very ſtrong, and uſed warm with a Flannel or Bruſh.

After this they muſt be turned looſe in a clean Paſture, and muſt be driven up again as ſoon as well dry'd, and all the ſore Parts muſt be well wetted with Lime-Water.

In both theſe Applications, the ſcurfy Parts of the Skin, as well as the ſcabby Places, muſt be regarded; and probably the doing this three Times, at two Days diſtance each, will be a Remedy.

If this fail, the Parts that have been thus waſhed and cleaned, muſt be anointed with a Mixture of equal Parts of Tar and Greaſe, and they will ſoon be perfectly well. No inward Medicines are required in this Caſe, for the Complaint is only on the Skin.

CHAP. XI.

Of the Red-Water.

FARMERS do not ſeem well to underſtand themſelves in reſpect of this Diſorder; but in ſome Places call an inward Diſeaſe, and in others an outward one, by this Name. The laſt is the proper Meaning of the Word, and it is a very dangerous Diſorder. Though it appears outwardly it is not entirely of the external Kind, as the former; but the Blood is always more or leſs affected with it, and conſequently Care muſt be taken accordingly, by inward as well as outward Medicines, in the Cure.

The great Miſtake has been the attempting it by outward Remedies alone, and this is the Cauſe why it has been found ſo difficult of Cure.

The Appearance of the Diſorder is about the Breaſt and Belly principally, but it will ſpread itſelf to other Parts. It is an Inflammation of the Skin that often raiſes it into Bliſters, and in thoſe is contained a ſharp Humour, thin, watery, and coloured with Blood. This is the Occaſion of the Name, and this the Diſorder properly called by it.

Nothing muſt be done to ſtrike it in, but the Cure regularly attempted by amending the bad State of the Blood.

Firſt, the Sheep that are affected with it, muſt be ſeparated, or otherwiſe it will be very apt to ſpread among them; and they muſt be put where there is ſweet Graſs and good Water, or the Medicines will take little Effect.

Mix half an Ounce of Flour of Brimſtone with an Ounce of Honey; work it well together, and then divide it into two Parts. Diſſolve one of theſe in half a Pint of Juice of Nettles, and give it every Day for a Fortnight. This Method obſerve with all that are diſordered.

Slit the Bliſters when they are full of this watery Humour, and having let the Matter out, wet the Place with Juice of Wormwood.

After four Days of this Courſe, bleed them pretty plentifully; and then continue the ſame Method till they are well.

CHAP. XII.

Of the Foot-worm.

SHEEP are liable to the breeding of Worms between their Feet; but this, like the other Accidents, is principally when they are kept in wet or damp Paſtures. It is very painful to them, and will make them pine away.

It is perceived by their frequently holding up one Foot; and by their ſetting it but tenderly down.

In this Caſe let the Foot be waſhed clean, particularly between the Toes, and there will be ſeen a little Lump like a Tuft of Hair. This is the Head of the Worm. It is to be taken out with Care, for 'tis of a tender Subſtance, and if it be broke in the Foot it will occaſion an Inflammation. The beſt Method is to open the Fleſh on each Side of it, and then, by Means of a Pair of Knippers, to take it very gently out.

Then dreſs the Wound with Tar and Greaſe melted together in equal Quantities, and turn the Sheep looſe.

It is better to put it into a freſh Paſture; for if the ſame Diſorder returns, it is generally worſe.

CHAP. XIII.

Of the Wild-Fire.

THIS is a very violent Inflammation, which appears in the Manner of a Saint Anthony's Fire, upon the Skin of the Sheep, in different Places; and when it is diſcovered on one generally infects more; often the whole Flock.

Our Fore-fathers were ſuperſtitious on this Occaſion, they bury'd the Sheep alive with its Feet upwards at the Door of the Fold; and ſuppoſed this acted as a Spell to drive away the Diſeaſe. We do not inherit theſe Errors. The Method to be obſerved is this.

Such Sheep as are infected with it, are to be ſeparated from the reſt: then bleed them, and prepare the following external Remedy. No other is required: and it is ſingular in this Diſorder, that although more violent than the Red-water, it does not at all infect the Blood, ſo that nothing inward need be given.

Bruiſe a good Quantity of the Leaves of wild Chervill, and add to them as much Lime-water as will make the Whole very ſoft. When it is thus beat up together and perfectly mix'd, add as much Powder of Fenugreek-ſeed as will reduce it to the Conſiſtence of Pap; then put it into a Pan, and ſet it in a cool Place. Rub the ſore or inflamed Part carefully with this every Evening, and make as much lie on as can be kept there; it will take Effect during the Time of Reſt, and is to be repeated as long as there is Occaſion.

CHAP. XIV.

Of Diſorders of the Eyes.

SHEEP are often affected with Colds falling upon their Eyes, and almoſt blinding them; and, at other Times, the ſame Accidents ariſe without any viſible Cauſe. The Remedy in either Caſe is the ſame.

Preſs out the Juice of Great Celandine, and drop a Quantity of it into the Eyes Night and Morning.

CHAP. XV.

Of the Dropſy.

SHEEP are often ſwelled with Water in their Bellies; and this, if not regarded in Time, is attended with certain Deſtruction. There are two Ways in which it is lodged; the one is between the outward Fleſh and the Rim; the other is within the Rim. In the firſt Caſe, the Cure is eaſy; in the other, nothing can be done.

The Method, in the firſt Caſe, is by a coarſe kind of Tapping.

An Opening is to be made in the Fleſh, and a Quill thruſt in; this will give the Water a free Paſſage out, and the Wound heals of itſelf, if if the Sheep be otherwiſe tolerably healthy: but when the Diſeaſe has been of long Continuance, and the Creature is emaciated by it, Nature will not have Strength to heal it: in that Caſe, the Sheep is to be examined daily, and the Wound dreſſed with Greaſe and Tar.

The Creature muſt be put into a freſh, dry, and wholſome Paſture, and then diſpoſed of as ſoon as recruited; for this is a Diſorder that never fails to return upon any Miſmanagement or Neglect in the Keeping.

CHAP. XVI.

Of the Rot.

THE Rot among Sheep is like the Murrain among larger Cattle, the moſt deſtructive of all the Diſorders to which they are liable, and the moſt to be dreaded by the Farmer. We have reſerved it for the laſt Conſideration, that what has been premiſed concerning the other Diſorders, may have led him ſo far into the Nature of Animals, as to make him perfectly comprehend all that relates to this.

This Diſorder is contagious, like the Murrain. Whenever it appears it uſually ſpreads thro' the whole Flock; and often over the whole neighbouring Country.

Preſervation from it is a Point of as much Importance as its Cure; indeed of more, becauſe the Cure is very uncertain.

The Cauſes of the Rot are various, but the principal is Careleſſneſs in the Owner. Sheep that feed at large upon open Commons, are much more ſubject to it than ſuch as have Shelter, and are taken due Care of at Nights; thoſe which feed in the dampeſt Grounds, are moſt ſubject to this, as to other Diſeaſes; and it frequently ariſes from a cold Seaſon and dribbling Rains coming on ſoon after the Shearing. Theſe taint the Skin, and bring on the Diſorder. Laſtly, want of Food will occaſion the ſame Diſeaſe; and the eating ſuch Graſs as is full of unwholeſome Plants. Theſe we ſhall particularize in a ſucceeding Chapter.

Such are the Cauſes of this terrible Diſorder in its original Appearance in many Places; but the Farmer, beſide theſe, is to obſerve that the worſt and moſt common is Infection.

Let him, at all Times, take Care to keep his Sheep out of the Way of theſe original Cauſes of the Rot; and he will find the ſame Care will preſerve them from moſt other Diſorders: and, beſide this, when the Diſtemper is any where near him, let him be careful to keep them clear and diſtant from all others.

Damp Grounds are always dangerous in this Reſpect; and in wet Seaſons eſpecially.

In theſe wet Times, the beſt Practice is quickly to remove the Flock to the upland Paſtures, and to give them ſome Hay as a Part of their Food.

The happieſt Thing that can chance to the Farmer in this Caſe, is to diſcover the Diſeaſe in Time. The firſt Notice of it will be perceived in the Eyes; and therefore in a wet Seaſon, and eſpecially at a Time when the Rot is

among the neighbouring Sheep, let him look into that Part. When a Sheep is infected with this Diſorder, the White of the Eyes looks dead and dull, and they have a weak faint Aſpect; the Creature is feeble, and his Skin is foul: the Wool is ſo looſe that it comes off in Handfuls with the leaſt Touch; and the Gums will look pale and the Teeth foul. He will be dull and liſtleſs in Motion; and heavy, as if his Legs were not able to carry him.

In this Caſe, the Diſeaſe is ſtrong upon the Creature. Many are generally infected at a Time, and the firſt Care muſt be to remove them from among the ſound ones: the diſtinction may be made by the Rules we have juſt laid down; and the ſick muſt be pent up in a cloſe Fold.

They muſt be allowed little Water; and their Food muſt be dry Hay and Oats. The beſt Way of giving theſe, is by Means of Troughs placed all round the Fold.

Bleeding, which is beneficial in moſt other Diſorders, is altogether deſtructive in the Rot. Some have try'd it; and what I write is in Conſequence of what I have ſeen as the Reſult of their Practice.

It has been obſerv'd univerſally, that Sheep fed in Salt Marſhes never have the Rot. This put it naturally into People's Thoughts to try Salt as a Cure; and we read Wonders of its Effects.

This alſo I have ſeen try'd, and ſometimes with good Conſequences; but never with the great Succeſs that is boaſted by many. Salt is a Preſervative againſt the Rot; and that is all we rationally learn from the Cattle not being infected with it, that feed in the Salt Marſhes; but it is not ſo certain a Cure.

The beſt kind of Salt for this Purpoſe, is Bay-ſalt; and the beſt Way of giving it, is by beating it to Powder, and then ſprinkling it among the dry Food. Though we do not adviſe the Farmer to rely upon it entirely, we ſhall recommend it, among other Remedies, in this Manner.

Bruiſe to Powder an Ounce of Grains of Paradiſe, and four Ounces of Juniper-berries dry'd; add to theſe two Pounds of Bay-ſalt and half a Pound of Loaf Sugar, grind them all well together, and ſprinkle ſome of this upon the Hay and the Oats that are given the Sheep.

Let this Courſe be continued three Days, and look from Time to Time into the Eyes of the Sheep, and examine every other Way, to ſee whether they mend or grow worſe. If there be Signs of Amendment, let the ſame Courſe be continued: if not, the following muſt be uſed. Steep four Pounds of Antimony in two Gallons of Ale, for a Week; then give the Sheep this every Night and Morning, a Quarter of a Pint at a Time.

Boil a Pound of the Roots of the common Avens, and two Pounds of the Root of Maſterwort, in two Gallons of Water, till there is not more than ſix Quarts remaining: ſtrain this off, and preſs it hard; then pour a Pint of it into a Pail-full of Water that is to be given to the Sheep.

By theſe Means, carefully managed, and under a good Regulation in the Articles of Cleanneſs, Dryneſs, and Warmth, the Rot will be often cured: this is all that can be promiſed upon the moſt ſanguine Expectations; for there are Times when the Diſeaſe is ſo rooted, and when the Temperature of the Air ſo favours it, that nothing will get the better of its Violence.

In the Courſe of this Method, if the Sheep have a Diſtaſte to their Food, becauſe of the Salt and other Ingredients mixed among it, they muſt be omitted for two or three Feedings; and then given in leſs Quantities: and if this take Effect the other need not be uſed; if otherwiſe, it will be beſt to take the Benefit of both together; the Salt and other Ingredients being ſprinkled among the Food, while the Drenches are given at the regular Times.

The INTRODUCTION.

THE Hog is not without its Diſorders, tho' they are not ſo many as thoſe which attend the Sheep. We ſhall not leave the Farmer uninſtructed in any thing that concerns his Intereſt; wherefore we name them here, and ſhall deliver the Symptoms by which they are known, and the approved Remedies.

CHAP. I.

Of the Fever.

WE have ſhewn how common a Diſeaſe a Fever is among Cattle of moſt Kinds; and the Hog is not exempt from it. The firſt Symptom of

of it is his forſaking his Food. The Hog has a ravenous Appetite from Nature, and when the Farmer perceives this he may be ſure ſomething is much amiſs. He will ſoon after be perceived to droop and grow faint, and if not taken ſome Care of will pine in his Fleſh, and the Diſorder will end in his Deſtruction.

The firſt Step towards a Cure is bleeding, and the beſt Place for performing this Operation is behind the Ears. If this Part do not bleed freely, his Tail is next to be cut; and between one and the other there will be got enough. A Pint is a proper Quantity to take away.

After the bleeding put him up warm, and give him a good hot Meſs made of Raſpings of Bread, Broth, and ſome chopped Penny-royal.

This is a Thing he is very fond of: the Bleeding will have given him ſome Relief; and he will take to it. As ſoon as he has well taſted it take it away.

This will make him ravenous, and he will ſwallow it with the Addition of a Medicine, which he would not have done before. This muſt be Philonium Romanum. Half an Ounce of it muſt be put into a Gallon of the Meſs, and he muſt eat a little at a Time. If he take above half he will have an over Doſe of the Medicine, therefore it muſt be taken away; and eight Hours he muſt be kept without any thing elſe. This will make him ready to take the Remainder; and that probably will make a perfect Cure.

It will be ſeen when he is well by his eating freely and heartily: and if he do not appear much recovered the next Day the Bleeding muſt be repeated, and the ſame Medicine given again.

CHAP. II.

Of the Murrain.

THIS is as fatal to Hogs, as to other Creatures of the Farmer's Stock.

It is owing to eating a vaſt deal of bad Food; and it diſcovers itſelf by the Waterineſs of the Eyes, and by the hanging of the Head to one Side: the Creature alſo is weak, faint, and refuſes its Victuals.

The Cure is this. Make a very good warm Maſh; and let them be kept all the Afternoon and all the Night faſting before it is ſet before them. Put into it half a Pound of grey Ground Liver-wort, and the Bigneſs of an Egg of Red Oaker, with as much Salt-petre as will lie upon a Shilling, powdered.

The Hog will generally be tempted to eat ſome of this after ſo much faſting.

When he leaves off, if he have ſwallowed ever ſo little, take it away.

Four or five Hours after ſet it before him again, and he will eat more; and by this Means he will be brought to his Stomach. All his Food muſt have a little Salt-petre and a good Quantity of Liver-wort in it. This will take Effect, if he be within the Reach of Remedy: but it is a Diſeaſe that is very often fatal. Cleanlineſs and good Management muſt aſſiſt, or no Medicines will do.

CHAP. III.

Of the Jaundice.

THE Hog is ſubject to an overflowing of the Gall, which would diſcolour the Skin if it were leſs thick and coarſe; but it ſhews itſelf by a Yellowneſs of the Eyes and about the Lips, and by a Swelling that riſes under the Jaws. The Cure is this. Bruiſe a good Quantity of great Celandine, and preſs out the Juice; add to it one fourth Part the Quantity of Vinegar.

Bruiſe a good Quantity of Wood-Lice in a Mortar; and when all is ready make a hot Maſh into as much of this as the Hog will eat at a Time; put a Pint of the Juice and Vinegar, and about a Quarter of a Pound of the bruiſed Wood-lice.

Let him faſt three Hours before he has this, and ſix Hours after it.

He will like the Maſh the better for theſe Ingredients.

If his Stomach be ſo bad that he will not eat it all at once, it muſt be taken from him as ſoon as he ſhews a Diſtaſte to it, and ſet before him again in half an Hour after.

A Hog will thus be led to eat almoſt under any Sickneſs: and this is the true Method of curing his Diſorders of whatever Kind.

CHAP. IV.

For Sickneſs at the Stomach.

THE Hog, though his Stomach is naturally very ſtrong, is ſubject to Sickneſs, and will caſt up his Food. If this be not obſerved it will encreaſe upon him, and he will waſte away. The Cure is by a Change in his Food; or if it be neceſſary the Addition of a Medicine with it: but the firſt uſually anſwers.

Keep him from all coarſe Meats, and give him Beans with a little Water. If this anſwer alone, it is better than giving Medicines: if it do not, give him every Day among his Food half an Ounce of Mithridate. It will at the ſame Time warm and ſtrengthen his Stomach; and he muſt be kept to good Food for Fear of a Relapſe.

CHAP. V.

Of the Meaſles.

THIS is a common Diſorder among Hogs, and ſhews itſelf in a Redneſs of the Eyes, and Foulneſs of the Skin, and in their neglecting their Food.

The beſt Remedy is this. Keep the Hog faſting the whole Afternoon and Night. Then ſet before him a good Meſs of Victuals; not large in Quantity, but hot and well prepared, and put into it forty Grains of Salt of Hartſhorn and two

Ounces of Bole Armoniac. It will all go down very well after this Faſt; and will make a good Beginning of a Cure. The ſame Method is to be followed every Day till he is perfectly recovered, and for a few Days after, for Fear of Returns.

CHAP. VI.

Of the Lethargy.

THE Hog will ſometimes fall into what is called the Sleeping-Evil or Lethargy. He will doze all Day long, neglect his Food, and pine away.

The Remedy is a Vomit; and the beſt in the World is this.

Gather a good Quantity of Wall Pepper, called alſo Sharp Stone Crop. Bruiſe this in a Marble Mortar, and preſs out the Juice.

Keep the Creature faſting all the Afternoon and Night, and in the Morning ſet before him a warm Meſs, into which put a Pint of the Juice of the Stone Crop. He will be tempted to eat by his long Faſt; and the Hog is not very curious about Taſtes. He will vomit ſoon after he has ſwallowed it; and that ſingle Doſe will frequently prove a Cure. If this be not ſufficient it muſt be repeated next Day.

CHAP. VII.

Of the ſwelling of the Milt.

WHEN a Hog is perceived to be giddy, to reel, and to run principally on one Side, the Farmer is to underſtand that it is his Milt that is ſwelled, obſtructed, or diſordered; and if he be not relieved he will forſake his Food, and pine to Death.

The uſual Cauſe of the Diſorder is a Surfeit in feeding upon Maſt.

The Cure is this. Bruiſe a good Quantity of the Leaves and Tops of common Wormwood, and preſs out the Juice: add to this ſome Juice of Penny-royal, and give the Hog a Pint of it in every Meſs of his Victuals till he is perfectly recovered; which will be known by the Steadineſs of his Walk and Quietneſs.

CHAP. VIII.

For a Purging.

HOGS that are taken with a Flux often have it grow to a great Violence upon them, and waſte with it till they are only Skin and Bone. It generally riſes from bad Food. The Cure is this. Make a good Meſs of Food for him, and put into it half a Pound of Acorn Huſks. Obſerve whether he grow better. If he do, repeat the ſame Method till he is perfectly cured.

If this do not ſucceed, give him in every Meſs of his Food a Handful of Tormentill Roots chopped ſmall. This ſcarce ever fails of compleating the Cure.

CHAP. IX.

Of Impoſthumes or Boils.

HOGS are ſubject to Boils and hard Swellings in various Parts; and the beſt Method is to open them, and let out the Matter at a proper Time. A common Knife anſwers this Purpoſe. The Farmer muſt obſerve to watch for their growing ſoft, that being the Mark that they are in a Condition to be cut. He is then to lay the Boil open the whole Length, and preſs it on the Sides to get out the Matter; and when this is done he muſt anoint the Place with Greaſe and Tar, and it will heal preſently.

CHAP. X.

Of Foulneſs of the Skin.

THE Hog is naturally an uncleanly Creature, and the Farmer muſt therefore take the more Care to be cleanly in his Management. A wet Stye will ſubject him to Colds; and Fevers will riſe from this: but if it be wet and naſty together, which is too common a Caſe, the firſt Conſequence will be a Foulneſs, Scurf, and Scabbineſs of the Skin. The Hog will pine, and all his Meat will be thrown away upon him, unleſs this be cured.

The Blood is often in Fault in theſe Foulneſſes of the Skin, and then inward Remedies are needful: the others may be tried firſt, and if they do not take Effect, that is a Proof theſe are wanted.

Firſt bleed the Hog under the Tail, as much as can be well got away: it ought to be a Pint at leaſt. Then prepare ſome very ſtrong Soap Suds. Rub common ſoft Soap upon a Scrubbing Bruſh, dip it in the Suds, and ſcrub the Hog well all over. This will clean him.

After this waſh him well with warm Lime Water, and make the Stye clean; give him dry Litter and wholeſome Food, and after two Days clean him again in the ſame Manner, and again rub him with Lime Water.

If this do not make a Cure his Blood is infected; and Flower of Brimſtone muſt be put into all his Victuals in large Quantities. This, with the Repetition of the other will cure. If the Skin be broken in any Place it muſt be dreſſed with Tar and Greaſe mixed together; and when he takes the Brimſtone inwardly, ſome ſhould alſo be mixed in Ointment.

CHAP. XI.

For ſore Ears.

SOmetimes the Hog will have a Soreneſs about the Ears from Dirt and Filth: more frequently it riſes from the Teeth of Dogs; and the worſt is when both theſe Cauſes come together. The Dogs make the Hurts; and the Dirt

Dirt occaſions them to feſter. The beſt Remedy is this.

Warm ſome Vinegar, and waſh the Ears thoroughly with this till they are clean; then make an Ointment of Tar and Greaſe in equal Quantities, and add a little common Soap. Rub the ſore Parts with this, and repeat it till the Cure is perfected.

CHAP. XII.

Of the Pox.

THIS is a Name by which the Farmers expreſs a Diſorder of their Swine, that ſhews itſelf outwardly in a Multitude of Pimples and Blotches; and keeps the Creatures miſerable, and makes them pine and waſte.

It riſes from Wet and Filth in their Styes, and from unwholeſome Food.

The Remedy is this. Make a hot Meſs for the Creature, and give in it an Ounce of Venice Treacle.

After it has taken this let the whole Skin be well cleaned with Soap Suds, and then wherever the Sores and Pimples are, uſe the following Ointment. Melt over the Fire two Pounds of Hog's Lard, and ſtir in half a Pint of Tar. When it is taken off the Fire, put to it as much Flower of Brimſtone as will thicken it when cold into a firm Ointment. Rub this upon the Hog every Night for four Times, and keep him dry and clean, and it will commonly make a Cure in that Time.

The Farmer muſt obſerve that this Diſeaſe is infectious; ſo that he muſt ſeparate thoſe Hogs which have it from the Reſt, and not put them together again till they have been ſome Time well, and he ſees there is no Return of the Diſorder.

BOOK XIII. SECT. V.

Of the Diſorders of POULTRY.

CHAP.
1. *Of the Pip.*
2. *Of the Roup.*
3. *Of the Flux.*
4. *Of Stoppage of Stools.*
5. *Of ſore Eyes.*
6. *Of Vermin upon Poultry.*
7. *Of Sores.*

INTRODUCTION.

THESE Animals have their Diſorders like others; and their Remedies are as efficacious and certain. The Farmer will the eaſier be a Maſter of this Part of his Care, becauſe there is not the Difference between one Kind of Poultry and another, that there is between one Kind and another of the four-footed Animals. Their Diſtempers are the ſame in general of whatever Kind they be, and the ſame Remedies will make a Cure.

CHAP. I.

Of the Pip.

THIS is a Diſorder peculiar to young Fowls, and it ariſes from the Want of Water. The natural Moiſture of the Mouth in this Caſe hardens upon the End of the Tongue into a kind of Scale, and this prevents their feeding.

The greateſt Care is required to obſerve in Time which of them have the Diſeaſe, for the Remedy is eaſy.

Let ſome Bay Salt be melted in a little Vinegar and ſet ready in a Saucer. Then let the young Creatures be taken up and the Scale looſened, and then pulled off from the Tongue with the Fingers. Then wet the End of the Tongue two or three Times over with the Vinegar and Salt, and turn the Chick looſe where he cannot drink for an Hour.

This will prevent a Return.

CHAP. II.

Of the Roup.

THIS is a Diſorder ſituated in a particular Part, but it will affect the whole Body. It is a ſmall Swelling of an angry inflamed Kind upon the Rump. The Fowls that have it grow ſickly, their Feathers ſtand rough, and they pine.

When they are ſeen in this Condition, let the Farmer ſeek for the Swelling and open it with a Knife. Let him ſqueeze out the Matter, and then waſh the Part with hot Vinegar and turn the Fowl looſe. This perfectly cures.

CHAP. III.

Of the Flux.

NO Kind of Poultry can thrive, unleſs they are properly in Order with Reſpect to their Excrements; and wrong Food will throw them into Diſorders in either Extream. This of the Flux is always occaſioned by their eating too great a Quantity of moiſt Food. The beſt Re-

medy is to give them ſuch Victuals for ſome Days as tends to the other Extream: and if this fails them, to have Recourſe to more powerful Things.

Peaſe Bran ſcalded is a Food they will eat very freely; and it will commonly very well anſwer the Purpoſe.

If this does not ſet them right in two Days, rub to Powder ſome dry Roots of Tormentil and mix with it: this never fails; and they preſently grow well and hearty.

CHAP. IV.

Of Stoppage of the Stools.

THIS is the contrary Extream, and is owing to a contrary Cauſe, namely the eating too much dry and binding Meat. It renders their Excrements too dry and hard, and prevents their voiding them ſo freely as they ſhould.

In this Caſe, as the former, the firſt Attempt to a Remedy ſhould be by the Food; and if that fail theſe Medicines muſt be added.

Thoſe Cures performed by a Change of Diet are always more natural and more laſting. For this give them Bread ſoaked in Broth; and if that fails, add to the Meſs a ſmall Quantity of Manna in this Manner. Skin off the fatteſt Part of ſome Liquor in which Meat has been boiled, diſſolve in half a Pint of this two Ounces of ordinary Manna, and then put in ſome Bread to ſoak.

They will eat this very freely, and it will certainly cure.

CHAP. V.

Of ſore Eyes.

THIS Complaint is very common among Poultry, and it is eaſily remedied. Their Eyes are often hurt by Accident in their going among Briars, and pecking one another; and they are alſo ſubject to ſwell and inflame with Colds. Theſe ſeveral Diſorders ſhew themſelves in various Parts of the Eyes and Eye-lids; but one Remedy ſerves for them all. This I have repeated often with Aſtoniſhment at its Succeſs.

Gather equal Quantities of Celandine, Ground Ivy, and Clown's Wound-Wort. Bruiſe them in a Marble Mortar, and preſs out the Juice. Add to half a Pint of this four Spoonfuls of White Wine, and dipping a Camel's Hair Pencil in it, rub the Eye-lids and Eyes carefully every Morning and Evening.

CHAP. VI.

Of Vermin upon Poultry.

NAture intended great Cleanlineſs for Birds, and in their wild State they never fail to obſerve her Dictates. When they are kept in a Yard they have not always Opportunity, and whenever it is omitted they ſuffer. Their Feathers keep their Skin ſo warm, that it is a natural Place for the breeding of Vermin of many Kinds: and what is more ſingular, every Kind of Fowl, as well as every Species of Beaſt, the Eagle and the Lion not excepted, have their peculiar Kind of Louſe, which will be ſure to appear when Uncleanlineſs encourages it.

The Means of Cleanneſs according to Nature are Plenty of good Water and ſome dry Ground; the Fowls will waſh themſelves in the one, and rub and dry themſelves in the other, whenever they have Opportunity; and thus keeping themſelves clean they are free from Vermin: but when they have foul Water it ſticks to their Skins, and gives Filth inſtead of cleaning it away.

Therefore to prevent the Evil, let the Farmer always take Care there be good Water; and a dry Soil in ſome Part of the Yard.

When it is come on the Remedy is this. Boil a quarter of a Pound of white Hellebore Root ſliced in two Quarts of Water to a Pint and a half. Strain this off, put it into a Quart Bottle, and put to it an Ounce of beaten Pepper, and half an Ounce of Scotch Snuff. Waſh the Skin wherever the Vermin are found with this, and it will prove a certain and a ſpeedy Cure. But if they be not thoroughly killed they will ſoon breed again.

CHAP. VII.

For Sores.

SORES and Swellings will often appear upon Fowls in different Parts of the Body, and they never fail to make the Creatures pine.

When Poultry droop, and their Feathers hang rough, let the Owner take them up and examine them carefully, he will uſually find ſome ſuch Diſorder.

The Cauſe is uſually bad Food, or bad Water, and ill keeping.

The Remedy is this. Melt together in a Pipkin equal Quantities of Reſin, Butter and Tar. When the Sore is found bathe it firſt with warm Milk and Water, and then dreſs it with this Ointment. Two or three Dreſſings uſually make a Cure; but they muſt be kept more carefully to prevent a Return.

End of the Thirteenth Book.

A COM-

A COMPLEAT BODY OF HUSBANDRY.

BOOK XIV.

Of the Diſtemperatures of Trees, Roots, and Herbage, from the Injuries done by Inſects, larger Animals, and Weeds.

In THREE SECTIONS.

SECT. I. *Of INSECTS.*

CHAP.
1. *Of Ants.*
2. *Of Beetles.*
3. *Of Worms.*
4. *Of Slugs.*
5. *Of Graſhoppers.*
6. *Of the Locuſt.*
7. *Of Caterpillars.*
8. *Of the Grub.*
9. *Of Flies.*

INTRODUCTION.

WE have laid before the Farmer at large the ſeveral Accidents to which his Crops and his Cattle are liable, from the Seaſons and other natural Cauſes; and it remains that we treat of thoſe Diſtemperatures which may be termed accidental, becauſe they are owing to the Hurts of Inſects.

Theſe, though very ſmall Creatures, yet by their Number are able to do great Damage. This will be beſt guarded againſt by thoſe who moſt thoroughly underſtand the Nature of thoſe Creatures. We ſhall therefore treat of theſe ſeverally according to their Kinds, and explain to the Farmer their Natures and Qualities; the Accidents, ſo far as they can be diſcovered, which cauſe their abounding at certain Times; and the Methods by which Vegetables of all Kinds, under the three diſtinct Heads of Trees, Roots, and Herbage, may be preſerved from them: founding all in this Part, as the preceding, on Experience.

CHAP. I.

Of the Ant.

THIS little Creature is a very troubleſome Enemy to the Farmer in many different Articles, and muſt be deſtroyed in ſome Caſes, and guarded againſt in others with the utmoſt Caution.

In Paſture Ground it raiſes Hills, which we have already ſhewn the Methods of cutting up and deſtroying: and in plowed Lands it will eat vaſt Quantities of the Seed before it ſprouts. Birds devour much of it, but they wait to ſee the Shoot; otherwiſe they know not where to ſeek for it: but theſe little Enemies, whoſe Number enables

enables them to do vaſt Miſchief, partly by what they deſtroy, and partly by what they carry away, follow it into the Ground, and are themſelves unſeen, as well as the Havock they make, till the Farmer finds the Misfortune in his poor Shoot. We ſhall direct him to perceive it ſooner, for then it is too late for Remedy.

The Ants are great Breeders, and they are diſtinguiſhed according to their Sexes: the Males have Wings, the Females none. There are ſeveral Kinds of them, the largeſt living in Woods; but theſe do little Miſchief. The ſmall common Ant is the Kind ſo hurtful to the Farmer.

Their Eggs are ſmall and round, and they are ſeldom ſeen or regarded; what is commonly called the Ant's Egg, is a thin Shell or Caſe, in which it lies while the Wings are forming. It is ſtrange, People could ſuppoſe Ants laid Eggs larger than their whole Body: but this is the Explanation of the Error. All Inſects that have Wings lie in a ſtill State ſome Time; the Silk-Worm, the Caterpillar, the Bee, and all others. This called the Egg is the ſame State of the Ant; and as they are utterly unable to move, during that Condition, the reſt take Care of them, carrying them to Places of Safety.

The Miſchief they do to Trees is by eating off the young Buds; but this is only of a few particular Kinds. Some Fruits alſo they are fond of, as is ſeen in Gardens. In Graſs-Grounds they do no Harm but by thoſe Hills, which are troubleſome enough. In new-ſown Corn-Fields they are moſt deſtructive, creeping in at the Chinks and Crannies of the Ground, and ſpoiling more than they devour or carry away. They are like the Wolf in the Fold, that will tear twenty Sheep to Pieces when he eats but of one.

Thoſe Kinds of Grain are moſt ſubject to this Injury, that have the thinneſt Skin and the ſweeteſt Flour. Therefore Wheat is moſt ſubject to their Depredations; and the ſmalleſt Wheat the moſt: partly as its Skin is thinneſt, and partly as it is eaſieſt of Carriage.

Barley they will attack, eſpecially that which is beſt, waiting till it is ſomewhat ſoftened in the Ground.

The other Kinds that ſuffer moſt, are Hemp, Flax, and Cole-ſeed.

Rye they are not very fond of; and all Kinds of Pulſe are ſafe, for they do not like them; the Skins are too thick, and the Meal too bitter.

In Gardens they are miſchievous in the ſame Manner, eating one half of the Seeds that are put into the Ground.

The Remedy is the deſtroying them; and this is to be done ſeveral Ways. Firſt let the Farmer find their Neſts, which are under Hedges, about the Stumps of old Trees, and on little Riſings of Ground.

Let him carry wet Straw to theſe Places, cover all the Neſts, and fire it. The Smoak will deſtroy them. And if once going over the Ground do not anſwer the Purpoſe, it muſt be repeated.

The Time for doing this is half an Hour after Sun-ſet, for they are then all together. In Gardens 'tis a good Method to pour boiling Water upon their Neſts, taking the ſame Time for it.

This is the Way to deſtroy Ants; but there is alſo a Method of preventing their Breeding. They hate Lime-Soot and Aſhes; theſe are all good Manures, and ſhould be uſed where Ants are moſt likely to come. 'Tis alſo a good Method to dreſs the Land with theſe after they have been choaked with burning the Litter. This perfects the Deſtruction of them, and they are ſeldom found to infeſt ſuch a Piece of Land afterwards.

CHAP. II.

Of Beetles.

THE ſeveral Kinds of Beetles are innumerable; we have them from the Stag-horned Kind, which is nearly as big as a Wren, to the ſmall black Beetle of the Roſe-buſh, which is ſcarce big enough to be viſible.

They are all bred the ſame Way, and many of them are great Devourers. The Farmer is aware of them in their winged State; but there is another Condition in which they do him greater Damage.

In the End of Summer they lay their Eggs juſt under the Surface of the Ground. Theſe hatch into thick white Maggots with ſix Legs, and after a Time of Reſt they come out with Wings, in the proper Form of a Beetle.

In the Maggot or Grub State, they eat the Roots of Graſs and Corn; and ſometimes they are very terrible in this Deſtruction. Eight Years ſince they almoſt caus'd a Famine in NORFOLK.

In the Beetle State they prey upon Corn in the ſame Manner as the Ants. They creep into the Cracks of the Ground, and devour the beſt Grains. Their Time of Miſchief is when the Grain is ſwell'd, and before it ſhoots.

They are more univerſal Deſtroyers than the Ants, for they have ſtronger Jaws, and leſs Nicety in their Taſte. There is no kind of Grain or Pulſe ſecure againſt them.

The Method of deſtroying them is this.

Juſt before the Sowing, carry ſome wet Litter into the Field; lay it in Heaps, and about Evening ſet Fire to it. That Fuel is beſt which makes moſt and thickeſt Smoak. They lie concealed in Buſhes and Hedges, but they fly at Evening with the Owls: this is therefore the Time to deſtroy them or drive them away. They are afraid of Smoak as much as the Ants, and they will be choaked in great Numbers by it; and what eſcape Deſtruction will get far off.

The ſame Manures that are uſeful againſt the Ant, are in like Manner ſerviceable againſt the Beetle: and it is a very good Method, where they are very plentiful, or a Field is particularly in Danger, to ſcatter Lime over it juſt after Sowing.

The ſteeping of Seed-Corn in Brines, and other Liquors, we have treated of in its Place: one great Uſe of that Practice is defending the Corn from theſe Devourers; therefore, wherever there is particular Danger either from Ants or Beetles, the Farmer ſhould be ſure to put thoſe Ingredients into the Brine which are moſt diſ-

agreeable to them or moſt deſtructive of them. Among all theſe Ingredients nothing defends Corn ſo well againſt the Beetle as Urine.

CHAP. III.

Of Worms.

THE Gardeners imagine that Worms do them no Harm; but thoſe who have obſerved the Courſe of Nature in the Field, can tell them they miſtake. There is a particular Time at which they feed upon the Grain; and they are ſo numerous, that the Deſtruction is very great.

The Worm is produced in the common Way of other Animals; but it is particular, that each Creature of this Species has both the Sexes. This promotes their large Increaſe: and as they have nothing of that Change to undergo, which we have ſhewn muſt happen to all Winged Inſects, there is no Stop in their Growth, and they arrive ſoon at Perfection.

There are three principal Kinds of Worms, the great and ſmall red Worms, and the Olive-colour'd.

Of theſe the ſmall red Worms are the moſt deſtructive. They are too common in good Lands naturally; and Multitudes are alſo brought on with the Dung.

The Time when they deſtroy the Corn is juſt when it has ſwell'd, and is beginning to ſhoot for the Blade and the Root. They at this Time prey upon its tender Subſtance, and are the Occaſion of ſometimes Two-thirds of a Crop miſſing.

A good Method of deſtroying them, is to drive a Number of Nails half way in upon the lower Part of the Plough which goes into the Ground. Theſe tear the Worms to Pieces in great Numbers; and they are alſo very uſeful in the breaking the Ground more fine.

This is therefore, on all Accounts, a very good Method.

Another Way is, to make Fires of wet Litter on different Parts of the Land. This deſtroys many of the ſmall Worms that are neareſt the Surface, and they are what do the Miſchief.

But the greateſt Remedy of all is to ſteep the Seed-Corn in a proper Brine.

The Taſte of Copperas is hateful to Worms; and they are no Way better guarded againſt than this.

It is ſuppoſed Hemp is deſtructive of them, or hateful to them, but Experience ſhews this to be an Error. I have ſeen Corn, ſteep'd in a Decoction of Hemp, devoured in the ſame Manner as if nothing had been done to it, and utterly eaten to Pieces. The beſt Preſervative of all, is to ſprinkle Lye over the Seed-Corn after ſteeping, and then to ſift Lime over it, and ſow it, well covered, with both. Theſe Taſtes continue with it longer than others, and are therefore more effectual.

CHAP. IV.

Of Slugs.

WE have named the principal Deſtroyers of Crops while in the Ground; and are now to conſider the Devourers of them when they have ſprouted: and of theſe none is ſo fatal, ſo numerous, or ſo hard to be conquered, as the Slug.

By this Name the Farmer expreſſes the naked Snail. It is of two Kinds, a large black and a ſmall brown one. The black is the greateſt Devourer; but the other is more apt to eſcape Deſtruction, becauſe unſeen, by being ſmall and of the Colour of the Ground.

Theſe are ſo very fruitful a Creature, that they will, in Places where there is any Shelter near, encreaſe faſter than it is poſſible to deſtroy them.

A Gentleman of Veracity, who has a ſingle Acre of Garden, aſſures me that he has, one Day with another, kill'd with his own Hand, ſixty or ſeventy of theſe Creatures, Morning and Evening, during the Summer, for theſe twenty Years, and yet he finds to this Day as many as ever.

In Gardens theſe Creatures eat the Hearts of new-planted Kitchen-Herbs; but in Fields they get a little within the Surface, and eat the firſt Shoots of the Crop.

The Stalk which is to ſupport the Ear, together with the Rudiment of the Ear, and of every Grain it contains, lie in this firſt Shoot, and this is eaten off by theſe miſchievous Creatures.

The ſmall brown Slug is moſt deſtructive of Wheat and other Grain; the great black Slug of Pulſe.

The ſteeping of Seed-Corn is of no Benefit in this Reſpect, becauſe no Taſte from thoſe Ingredients gets up to the Shoot. Therefore other Defence muſt be thought of againſt theſe Enemies.

Experience ſhews they are moſt frequent on Land manured with Dung; and that feweſt of all are found where the ſharpeſt Manures are uſed, ſuch as Lime, and the like.

Of all the Taſtes that can be thrown among them, two are found moſt diſagreeable to them; theſe are Lime and Soot.

This will give the Farmer his firſt Inſtruction againſt them.

He knows the Time when they will come to be miſchievous, and he has before him the Ingredients that can do moſt to prevent it.

Let him have ſome freſh and ſtrong Lime ready; and about eight Days after the ſowing of the Corn, let him have one or more of his Chimneys ſwept for Soot. Let him mix together equal Quantities of the freſh Soot and Lime, and ſprinkle it over the Ground.

This will greatly promote the Strength of the Crop, and at the ſame Time poiſon Multitudes of theſe Vermin.

If he can have the Advantage of a Shower about this Time, let him by all Means order the

Soot and Lime to be thrown on ſoon afterwards: if not, the beſt Time is very early in the Morning; becauſe they are then out, and upon the Surface of the Ground. The Lime falling upon their Bodies, kills them; and the Taſte and Effect of it will remain ſeveral Days upon the Land, as a Preſervative againſt thoſe which have eſcaped.

In ſmall Pieces of Ground, a Mixture of Soap-Lees and Tallow-Chandlers Greaves, deſtroys them utterly.

CHAP. V.

Of Graſhoppers.

THESE are Enemies of which the Farmer is not ſo much aware, as of many others which do him leſs Damage. They are not ſo common in his Crops as the reſt, which are in a Manner univerſal; but where they come they are extremely deſtructive.

They feed upon the Shoot as ſoon as it appears above the Ground, and are very miſchievous to the Summer-Corn, and other late ſown Crops. They eat theſe down ſo very deep, that frequently there is never another Shoot made, but the Grain dies, rotting in the Ground.

The Remedy againſt theſe Creatures is of a peculiar Kind. It is found that they cannot endure the Taſte of Bitters of any Sort. This is not ſingular; for many Inſects beſide theſe, and even ſmall Birds, are deſtroyed by thoſe Bitters, which we take with Safety and Advantage, in the ſame Manner as if they were the moſt fatal Poiſon. An Infuſion of Gentian will kill moſt of the ſmall Birds; yet, to us, it is a very wholſome and excellent Stomachic: on the other hand, there are Worms that feed on Pellitory of Spain, which is ſo hot we cannot endure it in our Mouths without Pain.

The Farmers who have, from Father to Son, a Tradition of this kind, boil Wormwood in Water, and ſprinkle it over thoſe Crops which the Graſhopper is devouring. But there is a much more powerful Remedy.

Coloquintida is the moſt hateful Bitter in the World; and a very ſmall Quantity of it will give its Taſte to a vaſt deal of Water. This ſhould be ſprinkled on the Crop, and will never fail.

CHAP. VI.

Of the Locuſt.

THE Graſhopper naturally leads to the Locuſt, as it is only a ſmaller Animal of the ſame Kind; but this terrible Deſtroyer we are little acquainted with in BRITAIN. We were threatened with a Swarm of them ſome few Years ſince; and, as it is poſſible, they may come at ſome other Time, tho' we have all the Reaſon imaginable to hope not, it may not be amiſs thus ſhortly to mention them.

They devour the green Crop of any Kind, and in any Degree of Growth; and when they come in ſuch Swarms as to cover the whole Ground to a great Depth, there can be no Remedy. If they ſhould ever threaten our Crops, it would naturally be in a leſs Quantity; and the Preſervation would be in the Method juſt directed. Coloquintida ſhould be boiled in Water, and the Liquor ſprinkled over the Field. This would indeed be worth a Tryal againſt other Inſects, particularly in Gardens; but it is not yet recommended upon Experience. It is a Taſte ſo extremely nauſeous, that probably no Creature would eat any thing wetted with it.

CHAP. VII.

Of the Caterpillar.

CAterpillars are of innumerable Kinds, like the Beetles and their Maggots. They are the Young of the Butterfly-Species, and are as various in their Form, Size and Colours, as thoſe winged Parents from whom they ſpring.

The Butterfly is directed by Nature to lay her Eggs upon ſome particular Plant; and there the Caterpillars are hatched. This Plant is to be their Food, therefore the Farmers and the Gardeners Crops ſuffer moſt becauſe they are well taſted: and the Creature devours immoderately, and does vaſt Miſchief.

After it has lived the appointed Time in this State, it ſpins a Web; and in that waits the Change into a Butterfly: thence it iſſues, like the Parent Animal, to lay the Foundation of another Brood.

Trees ſuffer as much as ſmaller Plants by theſe Creatures; they will eat up the whole Quantity of their Leaves ſometimes in a very ſhort Time.

In the Fields the Pulſe-kind are moſt ſubject to them; and it is very eſſential to guard againſt them.

In Plantations of Trees their Neſts ſhould be ſought, after the Leaves are fallen; for many Kinds of them breed in this Manner in great Numbers, the Eggs remaining in the Neſt or Bag all the Winter, and hatching juſt when the Leaves come out in Spring.

Theſe Neſts are generally at the Extremities of the Branches of young Trees, and the beſt Method is to cut off the Tip of the Branch and deſtroy them.

In Fields they have not this Courſe of Breeding, for what ſuffer moſt by them are the Summer Crops. When the Farmer ſees them in any Number, or perceives by their Havock that they are numerous enough to do him Miſchief, his Remedy is this:

Melt ſome Pitch in an Earthen Pipkin, and put to it ſome Flour of Brimſtone. Let it cool, and divide it into ſeveral Lumps.

Place ſmall Heaps of Straw in different Parts of the Field, and on each lay one of theſe Lumps of the Pitch and Brimſtone. Set Fire to the Straw, and the other Ingredients will melt and burn among it; and every Caterpillar that

is

is within the Influence of the Smoak, will fall off and periſh.

If once be not ſufficient, the ſame Practice may be repeated; and if the Farmer be diligent, he need not fear Succeſs. The Art is diſpoſing the Heaps in ſuch Manner, that no Part of the Ground may be free from the Smoak.

In Gardens and ſmall Plantations of any kind uſe the following Method.

Boil ſome Tobacco in Urine, and add to it ſome Soap-Lees. Sprinkle where the Caterpillars are, and it will deſtroy them.

CHAP. VIII.

Of the Grub.

WE have informed the Farmer in general, that the Grub is the Worm or Maggot produced by the Eggs of the Beetle. But there is one particular Kind of this Creature more deſtructive than the reſt; and when the Grub is mention'd without any particular Diſtinction, this Kind is meant.

This is a thick, ſhort, whitiſh Worm, with a hard red Head, and ſix ſhort Legs. It is found among the Roots of Barley and other Corn, and does prodigious Miſchief; eating off the firſt Shoot juſt above the Huſk. It feeds on the ſweet Matter of the Corn, which is at that Time a kind of Pap, like Cream; and leaves the Shoot to wither, and the Body of the Seed to decay.

This miſchievous Creature is the Produce of that Inſect we call the Cock-chafer, which is ſo abundant in Hedges in Summer-Evenings.

It is an endleſs Taſk to think of deſtroying the Grub, becauſe it lies at ſome Depth under the Ground; but there is no great Difficulty in preventing the Danger, by deſtroying the old ones, to whoſe Eggs the next Brood muſt be owing.

We have directed the Farmer to defend himſelf againſt Beetles in general, by making a great Quantity of a ſtinking and ſmothering Smoke; and the ſame Method is to be practiſed here.

He is to burn wet Stubble under all his Hedges; and he will by this Means certainly either deſtroy or drive them from his Grounds.

CHAP. IX.

Of Flies.

THESE are as innumerable in their Kinds as the Beetles or the Caterpillars, and no Inſect is more deſtructive of the Farmer's Crops.

We have already ſpoken of the Damages they do to Turnips, and to other young Shoots of uſeful Plants, under the ſeveral Heads where thoſe Articles are treated of at large; we ſhall therefore refer the Reader to their proper Place for theſe particular Conſiderations; but ſhall here give a general Account of this deſtructive Creature, and mention thoſe Particulars which have not occurred before in their Place; and with this cloſe the Account of the Farmer's Inſect-Enemies.

Among the Fly-kind thoſe which are the moſt conſpicuous are the leaſt hurtful. The larger Species being, for the moſt Part, harmleſs; and the ſmalleſt, in the higheſt Degree, miſchievous.

The Dragon-Fly, of which we have many beautiful Species, frequent about Waters, and which the Ignorant have diſtinguiſhed by the Name of the Horſe-ſtinger, has neither that, nor any other Hurt in its Diſpoſition: a harmleſs Inſect, form'd to wanton in the Fields of Air, to amuſe us with its Beauty, and the Rapidity of its Flight; and to do nothing to injure us. Its Brood are hatched in the Waters, where they are the Prey of Fiſhes, but never come in the Way of doing Mankind Damage.

It is much the ſame with the reſt of the large Kinds of Fly. They wander from Place to Place, and feed at Random upon leſſer Inſects, or upon uſeleſs Vegetables: but it is much otherwiſe with the ſmall Sorts. They herd together in innumerable Droves, ſettle upon the Boughs of uſeful Trees or Plants, and deſtroy and pervert the Courſe of Nature by their Sucking.

Wherever theſe appear, the Method for deſtroying them is by proper Smoaks; for nothing elſe can properly and perfectly reach them; but there are Ingredients to be uſed in this Manner, which ſpread their Effects ſo far, and operate ſo powerfully, that it is ſcarce poſſible for theſe Deſtroyers to eſcape or to ſupport themſelves againſt their Influence.

Books written on theſe Subjects, abound with Receipts for Liquors to ſprinkle over Plants covered with theſe little Deſtroyers; but theſe are trifling to the Method by Smoak, which is to be ſent among them much more eaſily, and ſpreads its Influence more univerſally.

For the Deſtruction of Flies of a larger Kind, that have ſeiz'd upon a Crop, a Quantity of Feathers may be burnt among wet Straw, and theſe give ſo offenſive a Flavour to the Smoak, that the Creatures will ſometimes be driven away entirely; but oftener, when only driven away thus, they return again. The Method that is therefore moſt eligible, is to kill them.

The Smoak of Brimſtone is, beyond all other Things, efficacious to this Purpoſe: there is a ſuffocating Steam attends it which no Creature can endure.

This is therefore very proper when it can be uſed conveniently, but it does not ſpread its Effects far. A few Matches burnt under a Place where there are a ſmall Parcel of theſe Vermin, will ſtifle them all, but there is no ſpreading the Influence of this over a whole Field.

As Sulphur is confined in its Sphere of Operation, there is a Drug called Orpiment, that is, of all known Subſtances, the moſt extended; and, happily for the Farmer, the Smoak of this is offenſive beyond all other Things.

A Dram of this will make as much Smother as a vaſt Quantity of Straw, Stubble, or any other ſuch Material; and the Smell is like that of Garlic, only vaſtly more offenſive.

This is the Farmer's beſt Safeguard againſt the Fly which ſeizes innumerably upon many of his Crops. He need not be afraid to uſe it, from

its

its having been called by ſome a poiſonous Subſtance; for that ariſes only from an Error: it is a common Thing to call yellow Ratſbane by its Name, but that is a Thing altogether different. Yellow Ratſbane is made by Art; but the right Orpiment is found natural in the Earth: and the Farmer's great Care muſt be to purchaſe it of an honeſt Perſon, and to explain what he does, and what he does not mean.

There needs no Addition to this; and there is very little Trouble in the uſing it.

Let the Farmer who has Crops over-ſpread with theſe Deſtroyers, take the Advantage of a Day when there is a little Wind; and place himſelf ſo that it may convey the Smoak he ſhall make directly upon his Crop. Then let him light a few Pieces of Charcoal, and ſet over theſe a Fire Shovel with an Ounce of Orpiment beat to Powder.

There will preſently riſe from it a thick white Smoak, of a moſt offenſive Smell. He will not be incommoded by it, becauſe the Wind drives it from him; but it will ſpread over a vaſt Space of Ground: if the Field be ſmall once burning will do; if larger, it may be repeated in two or three Places.

I have ſeen this tried in different Inſtances, and with various Effect. It hurts no Crop, and moſt Kinds of Flies are deſtroyed by it; but there are ſome it does not kill.

BOOK XIV. SECT. II.

Of Damages from larger Animals.

Chap.
1. *Of Mice.*
2. *Of Moles.*
3. *Of Birds.*

CHAP. I.

Of Mice.

FIELD Mice are as numerous as thoſe of the Houſe, and the Farmer often finds them as troubleſome, and ſometimes much more ſo. There are ſeveral Species of them; but they are all equally his Enemies: all feeding upon his Seed-Corn and Pulſe in the ſame Manner; and are all to be deſtroyed by the ſame Means.

Drier Lands are more ſubject to this Kind of Vermin than thoſe which lie wet; and of all the Kinds of ſowing, that under Furrow moſt expoſes the Seed to them.

In this Caſe, as the Furrows will fall ſomewhat hollow, they afford a Shelter to the Mice at the Time of their committing all their Havock.

The Farmer ſeems to contrive for their feaſting and Safety together in this Method; for the Corn or other Seed lies perfectly expoſed to them, and they are not expoſed to his Eye while they are feeding upon it.

In theſe Lands I have with great Concern often traced the Path of thoſe Devourers, and ſeen all eaten up, or carried away to ſome little Diſtance: for under the Covert of this Manner of Tillage they will make their Neſts and Granaries as it were in different Places; and the Seed ſhall be found ſtored up in one of theſe, that ſhould have covered a great Space of Ground with its Shoot.

The Huſbandman will by this ſee a great Diſadvantage attending that Kind of Tillage; and he will know in what Fields he is moſt to fear theſe Enemies.

Though this Manner of ſowing gives the Mice an Advantage, the other Way does not ſufficiently ſecure the Corn from them. When it is ſown in the common Way and harrow'd in, it is better covered; and there is a great deal more Trouble for them to get at it: but they are very induſtrious, and in this Caſe will dig after it, and tear up and deſtroy a great deal.

When it is ſown under Furrow they begin with it as ſoon as it is in the Ground; but when it is harrowed in they wait for its firſt Sprout. This gives the Farmer an Advantage, becauſe he knows exactly when he is to expect them; and it is a great Article of Safety to know when to guard againſt the Danger.

The careful Huſbandman is not in this Caſe to wait till he ſees the Shoot of his Seed; for the Mice have very quick Eyes, and they will perceive it a Day or two before he does: he is therefore to look to his Ground a Day or two before the Time of its being ſeen covered with the young Shoot; and then, as he knows the Devourers will be about, he is to prepare for their Deſtruction.

Traps are a very poor Method of getting rid of theſe Creatures. There is no Way well worth his Conſideration but Poiſon; and happily for him there are Drugs which will anſwer this Purpoſe of Poiſon to theſe Creatures, which are not literally and ſtrictly Poiſon to ourſelves. Theſe he is to uſe, and they will ſufficiently anſwer his Purpoſe. It would be a diſagreeable Thing to be meddling with Ratſbane; but there is no Harm in handling the Ingredients he has to uſe.

In the firſt Place let him conſider what Fields from their Soil are moſt likely to harbour Mice, and in what Places he has known them moſt miſchievous. Let him never ſow theſe under Furrow, for that takes from him all Opportunity of attacking his Enemies: they work under Ground as it were, and will never come into the Way of his Poiſon.

When theſe Fields have been ſown otherwiſe, and harrow'd over, the Mice muſt come upon the Surface and dig down for the Corn, and they will then certainly meet with any Thing he lays on the Ground for them.

Let him mix up a Peck of Barley Meal, a Pound of Powder of white Hellebore Root, and four Ounces of Powder of Staves-Acre; and when theſe are all mixed together by ſifting through a coarſe Hair Sieve, add half a Pound of Honey, and as much Milk as will work the whole into a Paſte.

Let this be broke into Pieces, and ſcattered over the Field at the Time when the Mice are known to be coming. They will eat it greedily, and it is certain Death to them. There is nothing in any of the Ingredients diſagreeable to the Taſte when thus mixed; and every Morſel of it will be devoured. The Mice will be kept from digging after the Corn; and at the ſame Time killed by the Ingredients.

This is the Method to be uſed juſt at the Time of Danger; but the Farmer who has a Field peſtered with theſe Vermin, will do well to be thinking at other Times alſo of deſtroying them.

They live at a ſmall Depth under Ground, and there breed in Abundance. The Paſſage into their Neſt is by a little round Hole, and theſe are eaſily ſeen in dry Weather.

On theſe Occaſions the Farmer ſhould go his Rounds with a Quantity of the Paſte before directed; and wherever he ſees a Hole throw in a Piece. A little Trouble of this Kind taken from time to time in the Heat of Summer when the Holes are moſt conſpicuous, would utterly root them out.

CHAP. II.

Of Moles.

THESE are ſubterranean Enemies of another Kind; but in their Way do as much Miſchief as the former. We ſee their Hills in Paſtures, where they work under Ground at a ſtrange Rate, and are very hurtful; but the Damage they do to Corn is much greater; and frequently comes upon the Farmer quite unexpectedly. He knows that the Ants and the Mice will eat the Grain when newly ſowed, and that the Slugs will deſtroy it when juſt ſhot up; but when theſe Times are over he is at Reſt on thoſe Heads. On the contrary, there is no Time at which the Mole may not deſtroy his Crop.

This Creature formed for living under Ground preys upon the Roots of Plants, and is fond in a particular Manner of thoſe of Corn; but beſide the Quantity they deſtroy by eating, they damage a vaſt deal more by undermining the Ground. 'Tis hard to be conceived what Havock one Way or other a ſingle Mole will make in a Field of Corn; or in how little Time, one of theſe Creatures will burrow through a third Part of an Acre in a Day; and this perhaps at a Time when the Corn is half grown.

The drieſt Lands are the moſt ſubject to theſe Animals, but they will get into any; and there is no Creature of all the Number to whoſe Injuries the Farmer is expoſed, againſt which it is ſo difficult to guard. There is no foreſeeing when they will come; but it is very important to know of their being in the Ground as ſoon as poſſible, in order to ſtop the Deſtruction.

The only Caution in the Farmer's Power is to obſerve whether there are any there at the Time of plowing; and if there be, he is to uſe every poſſible Method of deſtroying them: if not, he is to examine whether the Lands neareſt his own every Way be infeſted by them, or clear from them.

The freer they are they more likely he is to be clear of them; but there is no Certainty from this; for there are Times when they will come without any poſſible Manner of gueſſing from whence; and they will ſometimes have done irreparable Miſchief, before 'tis diſcoverd they are in the Place.

The next Caution to this of knowing when to expect them, is the deſtroying them when found. They are a very defenceleſs Creature, and not very cunning. Their only Security is the being hid under the Surface; and they betray themſelves in that Retreat by the Manner of their working.

The Huſbandman, whoſe Crop is ſuffering by them, is to look for the Tracks where they have gone; and theſe he will eaſily ſee by the different Colour of the new turned up Earth.

He is to follow the Courſe of one of theſe Paſſages, when he has got Sight of it; and he is to dig croſs Holes in it, and to watch the going out or coming back of the Mole. And wherever it is caſting, to ſtrike it through with an iron Inſtrument made for that Purpoſe. The Traps for catching them are alſo common, cheap, and of a plain Structure. Indeed the Deſtruction of this Creature is ſo eaſy, and ſo many are ready to undertake it at a trifling Price, that the Caution we firſt gave is the moſt important; which is the finding as ſoon as poſſible where they are growing miſchievous.

In ſome Places the Farmers content themſelves with driving them out of their Fields; and this is to be done by ſmoaking them, as other Creatures of a leſſer Kind are deſtroyed.

To this Purpoſe they open their Paſſages in ſeveral Places, and burn Heaps of Straw and ſome Brimſtone. This will drive the Moles out of a Corn Field ſpeedily enough; but this is not a ſafe or eligible Method. It is only ſending them out of ones own Ground into ones Neighbours, who may in the ſame Manner drive them back again. This is only a temporary Relief; and there is none wiſe or effectual but their Deſtruction.

CHAP. III.

Of Birds.

WE have gone through the Inſect and creeping Tribe of Enemies to the Farmer; and come to the flying. Theſe are as hurtful, and they muſt be guarded againſt by other Means. Thoſe who are unaccuſtomed to theſe Things will be ſurpriſed to ſee to how many Accidents, and to what a Variety of Devourers, the Huſbandman's Crop is expoſed. They will wonder any Care preſerves it from them; but certain it is that Care is neceſſary, or there will be but a poor Chance of eſcaping them.

Corn is open to a vaſt Variety of Birds, larger and

and ſmaller, from the Crow to the Sparrow; and they are continually ſeeking after it, from the Time it is out of the Seedſman's Hand in the Field, to the houſing it up in the Granary.

The ſmall Birds will follow the Sower, and one would think they would devour it as faſt as it comes from his Hand: from that Time they are daily ſeeking after every Grain that does not lie too deep for them; and they will in Spite of the beſt Care eat a great deal.

When it is about to ſhoot, the ſly Rook comes in. He perceives, as we have obſerved, the firſt Spire that gets above the Surface, before the Farmer's Eye ſees the leaſt Appearance of it; and he tears up a great deal. There is no Seed the Farmer ſows that is not a proper Food for theſe Devourers. They fall upon all alike, and happy for the Huſbandman it was, that in the old Way of ſowing, a great deal more Seed was allowed than was needful for the abſolute Growth.

The beſt Defence and Safety againſt theſe Devourers is the new Method of Huſbandry.

Drill ſowing gives great Security to the Seeds in general; and it limits the Time of the Danger of its being devoured, ſo that it is much more eaſy and cheap to protect it.

There is nothing of all that Loſs of the Seed as ſoon as thrown from the Hand; nor can theſe rapacious Creatures pick it up Day by Day afterwards as it lies expoſed; 'tis covered by that Practice, and the ſole Danger is juſt when it begins to peep above Ground. If a Boy or two be employed juſt at that Time to fright the Birds away, it is naturally ſecure at all others.

The ſteeping of Seed is another Defence againſt Birds; for they will hate the Taſte and neglect it.

A good Cuſtom would be to let a Perſon follow the Seedſman in the common Way with a Piſtol, diſcharging it frequently among the Cluſters that follow; hanging up any he chances to kill on a Stick by the Way.

This will defend the Seed in ſome Meaſure as ſown; and the ſame Practice will be uſeful afterwards when it begins to ſprout.

This will be needful whatever Method of Huſbandry has been followed; for the Rooks and other Birds will tear up the Seed from any Depth where they ſee its firſt Shoot.

Therefore about a Fortnight after the ſowing of Barley and other Summer Corn, and about ſix and twenty Days after the ſowing of Wheat, Rye, and the like, in Autumn, let a Couple of Boys with Piſtols be ſent into the Field. Guns are unmanageable for ſuch Perſons, and the killing is not ſo much the Purpoſe as the frighting. Any Servant of the Farmer's may with a Gun kill a Crow or two, or half a Dozen Sparrows, in any other Place, and they may be ſtuck up in the Field. The Boys need only fire Powder, and they will thus weary and fright the Birds away.

This Method and no other will defend the young Crop. It is but for a few Days that it is required, and no Servants the Farmer employs in his whole Profeſſion ſo well earn the Price he pays them.

Morning and Evening are the Time of Birds feeding. The Boys muſt be ſent into the Field an Hour before Sun-riſe, and muſt ſtay half an Hour after Sun-ſet; and theſe are the Times when they muſt be moſt vigilant. In the Middle of the Day there is leaſt Danger, and the moſt Damage of all is done at Day-break.

We have thus given the Farmer a general View of all the Dangers to which his Crops are expoſed from Animals; and the Methods found moſt ſucceſsful in preſerving and defending them againſt them.

One farther Damage there is to which he is expoſed, and this is from other Plants: of this we are to treat in the enſuing Chapters.

BOOK XIV. SECT. IV.

Of the Damage from WEEDS.

Chap.
1. *Of the Nature of Weeds.*
2. *Of the ſeveral Kinds of Weeds.*
3. *Of clearing the Ground of Weeds.*

CHAP. I.

Of the Nature of Weeds.

WHEN the Farmer has been at the Charge of enriching and tilling his Ground, he expects the Advantages of his Labours and Expence; and wiſhes the Improvements he has made in the Land may give all its Fertility to his Crop: but he is to conſider Nature ſows while he is ſowing; her Proviſion for keeping up the Species of Plants is very wonderful; their Seeds are ſcattered to great Diſtances, and where they fall they grow. While the Seeds of ſome Plants are winged with Down to make them float upon the Air, the Roots of others are ſo full of Life, that the leaſt Morſel of them remaining in the Ground will grow.

'Tis not with Plants as with Animals: in theſe the Loſs of a Limb or other eſſential Part cannot be reſtored, except in ſome few particular Kinds: but in Plants, while any thing remains the whole will be renewed.

Hence is the Origin of Weeds to be trac'd by the Farmer, and hence he will find them univerſal.

He is according to this diſtinct Manner of their Growth to divide them into two Kinds; the Perennial, or thoſe which commonly riſe from

Annual Weeds

Charlock

Poppy

Corn Marygold

Melilot

May Weed

Cockle

Sow-thistle

Perennial Weeds

Colts foot Leaves

The Colts foot Flower

Couch Grass

Thistle

Fern

Broad leaved Garlick

Crow Garlick

Wild Oat

Compleat Body of Husbandry, printing, by the Kings Authority, in weekly Numbers, at 6d Each.

from Roots left in the Ground; and the annual, which ſpring from Seeds brought on by the Winds.

A perennial Plant is one whoſe Root lives through the Winter, and ſhoots afreſh in Spring. The Seeds of theſe may be brought on by Winds; but they are moſt pernicious when they riſe from Roots; the Miſchief lying deeper, and the Plant being ſtronger.

The annual are ſuch as riſe from ſcattered Seeds: theſe flower during Summer, and die when they have perfected their own Seeds, which Nature ſcatters for a ſucceeding Crop.

From this Diſtinction the Farmer will ſee they are to be the Subjects of different Treatment. The perennial Weeds ought to be got out in the tilling of the Ground, their Roots being torn up by the Inſtruments: the annual are to be cleared away by a particular Practice afterwards; that is by hoeing: for they are not in Being when the Tillage is performed.

Beſide the Effect of Wind in bringing Seeds of theſe Plants upon the Ground, there is another Source from which many riſe: this is from Seeds buried there in former Tillage.

The Seeds of theſe, like thoſe of better Plants, will not grow unleſs they are near the Surface; but many of them will continue good when buried at a greater Depth, and grow when they are brought nearer the Air by Tillage.

The Farmer will ſee from this it is impoſſible to guard againſt Weeds, and that his Point muſt be to deſtroy them.

Every Method of right Huſbandry aſſiſts in reducing their Number; but none can utterly deſtroy their Seeds or Roots.

The better Fences are kept up, the fewer Seeds will be brought into the Grounds; becauſe the greater Part of thoſe that are brought by the Winds, are ſtopped by the Leaves, and fall there. This is the Reaſon why Hedge Bottoms are, in Spite of their ſheltered Condition, always ſo full of Weeds.

In the ſame Manner the better Tillage is uſed, the more the Roots of perennial Weeds will be torn up and taken out of the Ground; but in all this there will be ſtill Room for ſome Encreaſe.

Some Seeds will come in, and ſome will be ripened upon the Spot; ſo that notwithſtanding the beſt Care that can be taken to prevent their Growth, a great deal will alſo be required afterwards to deſtroy ſuch as riſe.

Weeds are in this Manner to be expected in all Places; and they will out-grow all Crops.

This riſes from a plain Reaſon: they are Natives of the Soil and Climate; and will therefore thrive better in it, than ſuch as are raiſed by Art.

It is a great Advantage in the Drill and Horſe-hoeing Huſbandry that they can from Time to Time be deſtroyed as the Crop is growing; and that every Time they are cut up the Ground receives a Kind of Tillage.

In the common Method they grow with the Crop; and as they are naturally more vigorous, they draw the greater Part of the Nouriſhment from it.

CHAP. II.

Of the ſeveral Kinds of Weeds.

EVERY Thing that grows without being ſown or planted, among a Crop that has been ſown or planted, is in that Place a Weed. The whole Benefit of the Tillage was intended for the Crop, and this robs it of a Part.

In general thoſe Weeds are moſt numerous which riſe from Seeds; and thoſe moſt difficult to be extirpated which come from Roots. *Sow-thiſtles* in Fields, and *Groundſell* in Gardens, are an Inſtance of the firſt Kind, and *Reſtharrow* of the latter; a Plant whoſe Root is ſo tough that it will impede the Progreſs of the Inſtruments according to its Name; and ſo full of Vigour in every Part, that the leaſt Morſel ſlightly covered will grow.

But there are ſome which have both theſe ill Qualities of propagating quickly and abundantly by their Seeds, and ſpreading and riſing alſo from their Roots.

Coltsfoot is an Inſtance of this Kind, its Seeds are winged with Down like the Groundſell or Sowthiſtles, and the Root is as tough and full of Life as that of *Reſtharrow*; theſe are the moſt pernicious of all.

Couchgraſs propagates almoſt entirely by the Root; but it ſpreads ſo faſt and ſo far, that nothing is more prejudicial.

From this Review of the ſeveral Natures of Weeds, the Farmer will know how he is to conduct himſelf in this Reſpect.

Let him when he is about to enter upon the Tillage of a Piece of Ground, conſider what are the Weeds upon it, and by that determine his Method of working: for all Lands the Horſe-hoeing Huſbandry is preferable in this Reſpect to the other, but moſt of all where the Ground is over-run with perennial Weeds. Let him take Care he know theſe by Sight, and underſtand what he is to do by their Appearance.

If he ſees the *Common Way Thiſtle*, this is one of thoſe of the worſt Kind, its Roots creeping and ſpreading, while its Seeds fly by Means of the Down.

Fern is another terrible creeping rooted Weed; and *Melilot* is hateful, not only by its abundant Propagation, but its abominable Flavour. Such as this hurt the Farmer two Ways; they impoveriſh his Crop, and give an ill Condition to the Grain. Wild Garlick does the ſame Damage.

Wherever there are an Abundance of theſe Thiſtles, and ſuch other of the rooted Kinds, let the Farmer underſtand that the Ground will coſt him much more Expence than under any other Condition, whatſoever Method he follows; and that his beſt Practice is to tear it up with the four coultered Plow, to harrow away the Roots immediately after every plowing, and to work it up by the Drill and Horſe-hoeing Method.

This will in a few Years perfectly clear it of the worſt Weeds that can infeſt it, be they ever ſo abundant; and if he follow any other Practice, they may remain Torments to him throughout the longeſt Leaſe.

The

The deep Plowing we have directed, and the repeated Harrowings will tear up and draw off a very great Part of theſe Roots; but as any ſmall Fragments will grow and ſoon encreaſe to any great Length, they would after this, be all the Care poſſible employed in it, riſe among the Crop, and ſtrengthen themſelves in the Ground during its Growth: whereas in the Horſe-hoeing Method, the very ſmalleſt Fragments as ſoon as they begin to grow will be torn up and thrown out in the Intervals, and very eaſily cleared from among the Rows of the Crop; and as theſe Intervals of the preſent Year are to be the Places of Rows of Crop in the ſucceeding, it cannot be but that the Ground muſt in a few Seaſons be perfectly cleared from them.

We have upon many Occaſions, and for various Reaſons, ſtrongly recommended this Practice in the preceding Parts of this Work; and we cannot but add this as one very eſſential Preeminence it has over the common Method, or any other ever brought into Uſe.

CHAP. III.

Of clearing the Ground of Weeds.

THE Conſideration of Weeds is very eſſential to the Huſbandman, becauſe ſcarce any of his Land eſcapes from being abundantly infeſted with them; and none is ever entirely free. They utterly deſtroy ſome Crops; and they never fail to injure others in Proportion to their Number and Nature.

The Hand-hoeing will, in ſome Caſes, anſwer the Purpoſe with the annual Weeds, as the Horſe-hoeing does with the others; but even this, in the common random Way of Sowing, is a Thing ſcarce practicable.

We have told the Farmer what he is to do in a Land over-run with the perennial Kind; and we ſhall ſuppoſe him now about to undertake a Piece that is tolerably free from theſe, but is abundantly covered with the annual ones. In this Caſe, as well as the other, the Horſe-hoeing Method is vaſtly preferable to any other, becauſe it not only effectually deſtroys ſuch as riſe after the Sowing, but makes them uſeful as a Manure: but if the Farmer is averſe to this, let him take a middle Courſe.

Where he ſees this abundant Growth of Annual Weeds, he may be ſure there will be a proportional Increaſe among his Crop: they muſt be deſtroyed, or they will ſtarve his Corn, by drawing to themſelves the far greater Part of the Nouriſhment: in the common random Way of Sowing, nothing is ſo difficult as to get out Weeds in the Growth; but in this Caſe it would be impracticable: therefore if he will not admit the Hoe-Plough into wide Intervals, at leaſt let him ſow by the Drill with ſomewhat narrower, that his Crop may ſtand clear, and well diſtinguiſhed from the wild Growth; and that the Hoers may eaſily and conveniently clear the Ground between the Rows with Hand-Hoes.

This is an Improvement of the common Practice, and will be of great Service; becauſe the Hoers, while they clear the Intervals between the Rows, may alſo draw up the Weeds by Hand that grow among the Crop in the Rows; but this is by no Means comparable in the Effect to the other Method.

The Hand-Hoers leave Parts of the Roots in the Ground, and after the firſt Shower there is a new Crop of the Weeds; but the Horſe-Hoe, tearing up the Roots, admits of no ſuch ſpeedy Return.

Theſe are the Methods the Huſbandman will find moſt ſucceſsful; but if he be ſo devoted to the old Method, that no Proſpect of Advantage can lead him out of his beaten Tract, then his proper Recourſe muſt be to a Summer's Fallow; and this muſt be carefully obſerved. The more the Ground is infeſted with Weeds, the more Care muſt be taken in the turning up the Ground.

A dry Summer will deſtroy a vaſt Number of them, when they are thus from Time to Time torn up as they riſe, and expos'd to the Sun; but there are Seeds that will lie under very little Diſadvantages a whole Year without ſhooting, and on theſe the Fallow takes no Effect.

The wild Oat is of this Kind, and ſeveral others; for there are Plants whoſe Seeds naturally lie twelve or eighteen Months in the Ground.

Theſe eſcape all the Farmer's Diligence in a Summer Fallow; they are not to ſhoot till the ſucceeding Spring, and then they come up with great Vigour, as if the fallowing had been a Preparation of the Earth for them.

Thus altho' a Summer's Fallow is the beſt Expedient the Farmer can uſe who will not follow the new Improvements, yet it is not to be compar'd in Efficacy to the Methods they offer for his Service.

It will deſtroy a great many Weeds, but the Horſe-hoeing Method utterly extirpates all; and that without the Loſs of the Seaſon ſacrific'd to the Operations of Fallowing.

We repreſent theſe Things to the practical Farmer as they are, on theſe repeated Inſtances; and hope the ſeveral Proofs of Advantages of various Kinds attending on the Practice of the new Method, will, when he ſees them thus candidly laid before him, induce him to follow it.

The Seeds that lie this length of Time in the Ground, and eſcape by that the Summer's Fallow, are not the only Source of a ſucceeding Year's Growth of Weeds; a vaſt Number are brought in with the Dung and other common Manures, and the great Quantity beſide riſing from Seeds, wafted in by Winds, join in ſhewing that a Method of Huſbandry which deſtroys them while the Crop is growing, muſt much more perfectly anſwer the Purpoſe, than one by which they are only kill'd before the Sowing.

Dung, which is the univerſal Manure in moſt Places, is compoſed chiefly of the Stalks of Corn; and, among theſe, there go into the Litter the Stalks of Weeds and their Seeds; therefore while the Farmer is enriching the Land for his Crop, he is alſo ſowing Weeds to reap the Benefit of it.

Theſe will be ſure to riſe in their full Number, and they will thrive upon the newly-enrich'd Soil abundantly. They can only be deſtroy'd

while the Crop is growing, becauſe they only grow with it. The Farmer will ſee by this, as by the other Inſtances, that there is no Way of deſtroying Weeds ſuited to his Purpoſe, or that can be effectual, but the doing it while the Crop is growing.

He is ſenſible of this; and in ſome Caſes attempts it, by weeding among his Corn: but this is a Method the worſt calculated for real Benefit of all that ever were introduced into Huſbandry.

The Feet of the Weeders muſt do harm, and it is often more than their Hands do good. The Corn ſtanding irregularly, there is no avoiding trampling ſome of it down; and in other Crops which more reſemble Weeds in their firſt Shoot, there is beſide the Damage of the treading them down, the Danger of tearing them up; and great Miſchief happens both ways.

This is the Caſe with the annual Weeds, and it is ſtill worſe with the perennial: they cannot be torn up, becauſe that would tear up ſome of the Corn with them. All that can be done is the cutting off their Heads; the nearer the Root, the better; but ſtill however near this is done, the Remedy is only ſlight, temporary and imperfect; the Root remains in all its Vigour, and new Shoots preſently riſe in the Place of the old one. Theſe are commonly more numerous than the old, and conſequently they draw more Nouriſhment. Thus what appears a Remedy, is, in theſe Caſes, an Increaſe of the Diſeaſe.

All this is obviated by the Horſe-hoeing Huſbandry: that tears up and deſtroys all Weeds without any poſſible Damage to the Crop. This is plain to Reaſon, and it is found true by Experience; and with this laſt Recommendation, added to the many we have occaſionally named before, we cloſe this Part of our Treatiſe.

End of the FOURTEENTH BOOK.

A COMPLEAT BODY OF HUSBANDRY.

BOOK XV.

Of the poiſonous and hurtful Plants native of this Kingdom.

In TWO SECTIONS.

SECT. I. POISONOUS.

CHAP.

1. *Of Henbane.*
2. *Of Hemlock.*
3. *Of Deadly Nightſhade.*
4. *Of Water Dropwort.*
5. *Of Dogs Mercury.*
6. *Herb Chriſtopher.*
7. *Of Water-Crowfoot.*
8. *Of Yew.*

SECT. II. HURTFUL.

9. *Of White Rot, or Cotyledon Paluſtre.*
10. *Of Red Rot, or Ros Solis.*
11. *Of Louſewort, or Pedicularis.*
12. *Of Spurge-Laurel.*

The INTRODUCTION.

WE have thus, in a compleat Courſe of the Practice of Huſbandry, to the utmoſt of our Power, acquainted the Farmer with every thing he ought to know, and every thing he ought to do for the Succeſs of his Buſineſs and Improvement of his Crops. We have occaſionally, together with what he is to undertake, ſhewn him what he is to avoid, and there requires but the ſingle Article we are here to treat of, to finiſh the Deſign; which, if the Execution have been at all proportioned to the Intent, and to the Aſſiſtances received for compleating it, we hope will be a Benefit to the Public and to Poſterity.

In treating of the Diſorders of Cattle, we have mentioned their eating unwholſome Plants; and it is theſe we are to conſider more at large in this Place. This Kingdom does not afford many; but what there are the Huſbandman ought to know, for the Security of his Stock, and of the young among his Family.

Inſtinct gives Creatures a general Direction not to feed on hurtful Things; but they ſometimes neglect the Caution; Appetite in them, as well as in ourſelves, getting the better of all other Admonition. To us who have Reaſon, this Inſtinct is not given; and while too young to exert it, we are in the Way of Danger; nor are we at any Time, without due Information, altogether above the Power of Accidents of this Nature.

It is for this Reaſon we ſhall here give the Huſbandman the full and diſtinct Knowledge of what hurtful Plants will fall in his Way, adding to their Deſcriptions the Aſſiſtance of Figures, that he may deſtroy them wherever he perceives them riſe.

Mentane

Hemlock

Deadly Nightshade

Burnet Saxifrage

Dog's Mercury

Herb Christopher

Water Crowfoot

The Yew Tree

White Rot

Common Sundew

Red Rattle

Spurge Laurell

Engrav'd for The compleat Body of Husbandry *printing, by the Kings Authority in Weekly Numbers at 6.d Each.*

BOOK XV. SECT. I.

Plants abſolutely poiſonous.

OF theſe we are ſo happy, that there are no more than eight naturally wild in ENGLAND: the Farmer will, from the Figures and Deſcriptions, eaſily be acquainted with this ſmall Number: we ſhall give him an Account of their Effects, not exaggerated by Fancy of falſe Hiſtories, but from Experience and Authorities above the Reach of Queſtion; and he will thus know what he is to avoid, both with Reſpect to his Family and his Cattle; and why he is to avoid them.

CHAP. I.

Of Henbane.

HENBANE is a large ſpreading Plant: it is capable of doing great Miſchief; and, unhappily for the Farmer, it is not confined to Woods or remote Places, but grows naturally upon Ditch Banks, and is common almoſt every where.

Nature which has thrown it thus in the Way of Mankind, yet has ſtamp'd ſo ſtrong a Mark of its Qualities in every Part, and given Notices of its hurtful Properties ſo evidently to all the Senſes, that ſhe ſeems to have rais'd a ſufficient Caution againſt any Danger.

It differs from all other Plants in the Form and Hue of its Leaves: its Flowers are of a deadly diſmal Colour; and the whole Plant forbidding in its Aſpect. The Eye marks it for a Poiſon; and when offered to the other Senſes, they anſwer in the ſame Language. Its Taſte is filthy and nauſeous, but this cannot eaſily come into Tryal; for its Smell, which will be perceiv'd firſt, is offenſive and forbidding.

By this diſmal Look, and this forbidding Smell, has Nature warn'd Men to beware of Henbane tho' they ſee it frequent about their Dwellings: we ſhall prevent the Poſſibility of miſtaking it for any other Plant, by adding the Deſcription of its ſeveral Parts.

The Root is thick, long, and irregular in its Shape. From this riſe eight or ten Leaves. They are very large, long, and of a whitiſh or a greyiſh green Colour. They are very deeply indented at the Sides, and of a ſtinking filthy Smell.

The Stalk grows up in the midſt of theſe, and is whitiſh, hard, woody, full of Branches, and two Feet high. The upper Branches ſpread out very much.

Many Leaves grow upon this, like thoſe that firſt riſe from the Root: and of the ſame Smell.

The Flowers are numerous and large, but they are not conſpicuous. They are hollow, like a Bell, and are of a dead Colour, vein'd in a very curious Manner with Purple.

After theſe come ſhort thick Seed-veſſels, which are full of ſmall brown Seeds.

Every Part of this Plant is poiſonous, and it deſtroys People by throwing them into Drowſineſs, like a Lethargy, with Convulſions.

Cattle will ſometimes eat the young Leaves of it; and this throws them into the Sleepy Evil, deſcribed before: if they have eat a great deal no Medicines can recover them. Hogs will grub up the Root, and it affects them in the ſame Manner.

Chickens will pick out the Seeds; and if they eat a large Quantity, they die by it. This is the Reaſon of its Name *Henbane*.

Theſe are ſufficient Reaſons why the Farmer ſhould let none of it grow near his Fields; but there is yet greater Cauſe for tearing up in his Yard where it is very common.

There have been Inſtances of Country Fellows eating the Roots by Miſtake; and they have dy'd in the moſt miſerable Manner in Convulſions, and with gnaſhing of their Teeth.

The Seeds of white Henbane which are uſed in Medicine, are thoſe of a different Plant. This is altogether poiſonous.

CHAP. II.

Of Hemlock.

THIS is another of thoſe poiſonous Plants which Nature, for Reaſons to us unknown, has made to grow in great Abundance near our Habitations.

It is not characteris'd like Henbane, by a peculiar forbidding Aſpect; yet it is a gloomy-looking Plant, and by no Means inviting to the Eye. Its Smell alſo is heavy, and ſeems to the moſt ignorant Perſon unwholſome.

There is a Sort of Hemlock which grows of itſelf in Gardens, and reſembles Parſley; but this, tho' a very unwholſome Plant, is not the poiſonous Kind. That is the large Kind which grows wild in Hedges; and it is ſufficiently diſtinguiſhed by its Height, its Aſpect, and its painted Stalk, to prevent any Miſtake to the Farmer, who ſhall have obſerved its Deſcription and its Figure.

The Root is white, thick, long, and of an unpleaſant Smell.

The Leaves that grow from this are very large, two Foot broad, but divided into innumerable ſmall Parts, in a regular and beautiful Manner; and they are of a dull and blackiſh green.

The Stalk grows up in the midſt of theſe, and it is two Yards high, and as thick as a Child's

Child's Arm. It is of a deep dingy green, but painted in a very ſurpriſing and beautiful Manner with Manner with Purple, ſo that it reſembles the ſpeckled Skin of a Snake.

The Flowers are white, they are ſmall ſingly, but they ſtand in thick and large Cluſters at the Tops of the Branches.

The Seeds are roundiſh, of a pale green Colour, and ſtriated. Two come after every Flower.

There are ſeveral other Kinds of this, beſide that firſt mentioned, and the preſent; eſpecially a very ſingular one with a thick Stalk, that grows in Waters. They are all of a poiſonous Quality; but this common Hedge Kind worſt of all.

The Stalks are the moſt poiſonous Part; and next to them the Seeds. Some pretend the Root has ſcarce any bad Qualities; but this is not confirmed upon ſufficient Experience.

The Athenians extracted the Juice of Hemlock from the lower Parts of the Stalks before the Plant roſe up to flower; and with this Poiſon they executed Criminals inſtead of hanging. Socrates died by this Doſe.

The Knowledge of the poiſonous Qualities of Hemlock is ſo common, that we do not hear of any bad Effect among our own Species who are guarded againſt it: but many of thoſe Diſeaſes of Cattle which perplex the Farmer and the Farrier, and at length end in the Creature's Death, are the Effect of eating the young Shoots of this Plant. Some Birds feed upon the Seeds without Hurt; but they are fatal to other Creatures.

CHAP. III.

Of Deadly Nightſhade.

THIS is a Plant not ſo common about Towns and Houſes as the others; and that wherever it is ſeen ſhould be rooted up, for it is fatal to Children. Nature, which has not planted this in the Way of Men ſo much as the other two, has not been careful to mark it as thoſe for a Thing to be dreaded. On the contrary, it is an extremely beautiful Plant, yet with a ſomewhat melancholy Aſpect.

The Root is long and thick, and it creeps under the Surface of the Ground.

From this riſe many large and broad Leaves of a deep green Colour, and not at all notch'd or divided at the Edges.

The Stalk is round and thick, divided into many Branches, and a Yard high. It is full of Leaves like thoſe from the Root, and toward the Top has many Flowers.

Theſe are large, hollow like a Bell, and of a duſky Purple Colour.

After theſe come Berries which are large, and of a very tempting Aſpect; they are of a ſhining and jetty black, and are as big as large black Cherries. They are ripe in July and Auguſt.

Children are tempted to eat theſe, and they are always fatal. A ſingle Berry will bring on Convulſions; but they ſeldom ſtop with one or two. They commonly die miſerably a few Hours after eating them.

I remember an Inſtance of two Children in Northamptonshire, who eat immoderately of them and did not live to get Home. They were track'd from the Plant to the Place where they fell by bloody Stools, and there died in Convulſions.

CHAP. IV.

Of Water Dropwort.

THIS is a Plant, which, like the former, has been fatal to many Perſons who have been tempted by the cleanly Look to eat of it; and which the Farmer ſhould know, that he may guard againſt it with the utmoſt Care. The Root in this Plant poſſeſſes the greateſt Degree of Poiſon.

It always grows by Waters, and is very common in moſt Parts of the Kingdom.

The Root is compoſed of ſeveral long and large Pieces which reſemble Parſnips in Shape and Colour, and are of a ſharp Taſte.

The Leaves that riſe from theſe are large, and of a pale green, and they are divided into a great Number of Segments.

The Stalks riſe ſeveral together, and are upright, divided into many Branches, and a Yard high.

They have ſeveral Leaves upon them like thoſe from the Root, and of the ſame faint Colour.

The Flowers are ſmall and yellowiſh; they grow in great Tufts at the Tops of the Stalks, and after every one of them there come two ſmall Seeds.

The Roots when they are freſh taken up have an inviting Aſpect: they run out a white Juice like Milk when cut; and this preſently after turns yellow.

Many have eat of them, and all died. We have Inſtances of the ſad Effects from very early Time; and within theſe few Years the ſame fatal Scene has been repeated. They take the ſame Effect whether raw or boiled; and thoſe who eat them die raving and in Convulſions.

CHAP. V.

Of Dog's Mercury.

THIS is another of thoſe Plants which tempt the Ignorant by their pleaſing Aſpect, and are in their Effects fatal. The whole Herb appears very inviting; it is freſh and green at a Time when every thing elſe is dead; and many have eat it raw or boiled, and periſhed by it.

It is a Plant common under our Hedges, and on which Nature has ſtamped no Mark of Caution: on the contrary it has a very alluring Look.

The Root is ſlender and long; it divides into many Branches, and ſpreads under the Surface of the Ground.

The Stalks are round, upright, not at all branched, of a faint green, and about a Foot high.

They are almoſt naked toward the Bottom, but nearer the Top there ſtand many Leaves; theſe are long and notched at the Edges; and they are of a very bright pleaſant Green.

The Flowers are inconſiderable. On ſome Parts there ſtand Spikes of a greeniſh Colour, and on others Seeds, which are as it were double.

The Plant is in full Vigour early in Spring, and its freſh, green, and wholeſome Look has tempted many to boil it for Food. Whole Families have been poiſoned by it. The Children have generally died; ſometimes the Father and Mother have recovered; but in other Inſtances all have periſhed together. They die in Convulſions, and in the greateſt Agonies.

CHAP. VI.

Of Herb Chriſtopher.

THIS is a Plant as fatal in its Effects as any; but very happily it is found in few Parts of this Kingdom, and there generally in Woods, and far remote from Dwellings.

The Root is long, thick and whitiſh.

From this riſe ſeveral large Leaves, ſupported on long, reddiſh Foot-ſtalks. Each Leaf is divided into many ſmall Parts, or is as it were compoſed of many ſmall ones; and it is of a deep green Colour.

The Stalk riſes in the Midſt of theſe, and is round, upright, reddiſh, and two Feet high.

Several Leaves grow upon this, which in all Reſpects reſemble thoſe from the Root, and are when rubbed or bruiſed of an unpleaſing Smell.

The Flowers ſtand in long Cluſters upon ſmall Stalks growing at the Top of the Plant, and from the Boſoms of the Leaves; they are ſmall and White.

The Berries that follow theſe hang in the Manner of Bunches of Currants, and they are of a ſhining black Colour. They are ripe in Autumn.

Children who have gone out to gather Blackberries have been tempted to eat theſe, and have in Conſequence died in Convulſions The Plant has been from this named Bane-berries. The young Shoots alſo poiſon Cattle.

CHAP. VII.

Of Water Crowfoot.

EVERY one knows the common Crowfoot of the Meadows, which Children call Butter Cups: this is of a burning and cauſtick Quality; but there is one Kind of it which has been ſometimes eaten, and has never failed to prove a very deſperate Poiſon, deſtroying People in a particular and very frightful Manner. This Kind is common in watery Places, and is perfectly different from all the others, and indeed from all other Plants; ſo that the Huſbandman will have no Difficulty in knowing it at Sight, by the Means of our Deſcription and Figure.

The Root is compoſed of a great many fine white Threads.

The Leaves riſe from this, a great many together, and they are broad, of a roundiſh Shape, but irregularly divided about the Edges into three or more Parts: they are ſmooth, of a ſhining Surface, and of a pale yellowiſh green Colour.

The Stalk riſes up in the Midſt of theſe, and is very thick, fleſhy, of a pale green Colour, two Foot high, and divided into a great many Branches.

Several Leaves grow upon this which in all Reſpects reſemble thoſe from the Root, and are like them of a pale green Colour.

The Flowers ſtand at the Tops of the Branches: they are very ſmall and yellow; and they reſemble the common Crowfoot Flowers in Shape, but they are paler coloured.

The Seeds follow theſe, and are ſmall and green; they ſtand cluſtering together in a Kind of oval Heads, and eaſily fall off when touched.

The Plant is common about the Edges of Ponds; and where Water has ſtood in Winter. Its Leaves are up early in Spring, and by their Freſhneſs tempt Cattle and ſometimes Men to eat them. They are the Cauſes of many of thoſe Diſorders which affect Cows and Oxen in the early Seaſon.

Their Effect on Mankind is terrible: Death is a certain Conſequence; and they die laughing.

CHAP. VIII.

Of Yew.

THE Yew is a Tree too well known to need a long Deſcription. Its Trunk is covered with a reddiſh Bark. Its Branches ſpread irregularly, and its Leaves are compoſed of many ſmall and narrow ones, which ſtand regularly on the two Sides of a Stalk in Rows, and are of a blackiſh Green.

The Fruit is of a particular Form and Appearance; it is compoſed of a green Button placed in a red juicy Cup, reſembling the Huſk of an Acorn.

The Tree is wild in our Woods in many Places, and is planted alſo for Ornament; being an Ever-green.

Children eat the juicy Part of the Fruit, which happily is not poiſonous, or in the leaſt of Kin to the reſt of the Tree.

The Farmer's Care muſt be to keep his Cattle from the Leaves. They will frequently eat the Clippings thrown out of Gardens, or the young Shoots when it is planted where they can get at it.

When they eat but little of it, they fall into Diſorders which often end in their Death: but when they ſwallow it in a larger Quantity, they die preſently.

BOOK XV. SECT. II.

Such as are not abſolutely poiſonous, but very hurtful.

CHAP. IX.

Of White Rot.

THIS is a little obſcure Plant, which often grows in great Abundance where it is little minded, and is the Cauſe of very terrible Miſchief to the Farmer.

It conſiſts principally of a Parcel of Stalks which lie upon the Ground; and ſpread themſelves about in a very irregular Manner. They are as ſmall as a Packthread, and of a pale whitiſh green. Sometimes they riſe a little upwards, but rarely.

Theſe Stalks ſend down little Tufts of fibrous Roots in various Places; and generally where theſe ſhoot from the lower Part, there riſe alſo from the upper Side, Leaves.

Theſe are as large as a Half Crown-Piece, and of a round Shape, but indented irregularly at the Edges. The Stalk which ſupports them, is long and ſlender; and it is inſerted not at the Edges, as in moſt other Plants, but in the Middle.

The Colour of the whole Leaf is whitiſh, and it is of a thin Subſtance.

The Flowers are very ſmall and inconſiderable: they are of a pale Colour, and they ſtand on ſlender Foot-ſtalks riſing from the Boſoms of theſe Leaves, or the Part where their Foot-ſtalk joins to the main Stalk. The Seeds are ſmall and brown.

This is the whole of a Plant, whoſe low Condition renders it unſuſpected by the Farmer, while it is the Ruin of his Flock.

It is very common in marſhy Grounds, where it runs cloſe to the Bottom, and is hid among the Graſs.

The Sheep find it, tho' their Owner does not perceive it; and they eat of it abundantly among the Graſs, being pleas'd with its ſharp Taſte. The Conſequence is, their falling into that terrible Diſtemper the Rot: from which few, that have ſwallowed any large Quantity of this Herb, eſcape.

CHAP. X.

Of Sun-dew.

THIS is another of thoſe Plants which is fatal to Sheep; and which, in the ſame Manner, is often overlook'd by thoſe who know its bad Effects; by Reaſon of its Smallneſs: but in this they are the leſs to be excus'd, becauſe, tho' a very little Plant, its Singularity renders it conſpicuous.

It is but about ſix Inches high, but it ſtrikes the Eye at firſt, by being all over of a red Colour; and, upon a cloſer Examination, it ſurpriſes yet more, by being covered with large Drops of Water in the moſt violent Heats: it hence obtained the ENGLISH Name Sun-dew; and it is alſo called frequently Roſa Solis.

The Root is compoſed of a few ſmall Fibres.

The Leaves riſe in a little Tuft eight or ten together. Each is ſupported on a long ſlender Foot-ſtalk. They are of the Bigneſs of a Silver Penny, round, of a red Colour, but covered with very long and ſtiff yellow Hairs: upon theſe reſt the great Drops of Water.

The Stalk riſes in the midſt of theſe, and is about ſix Inches high: it is upright, very ſlender, and has no Leaves upon it. It generally divides into two Parts at the Top, but otherwiſe it has no Branches.

The Flowers grow in a Row at the Top: they are ſmall and white; and they ſeldom open perfectly. The Seed-veſſel is ſhort, and the Seeds are very ſmall.

This Plant grows, like the former, on boggy Grounds; and it has, like that, a ſharp Taſte, for which the Sheep like it. They eat it too frequently, and its Effects are the ſame as thoſe of the former. It brings on the Rot; and thoſe which have eat much are incurable.

CHAP. XI.

Of Louſewort.

THIS is another Inhabitant of the wet and marſhy Grounds, which is hurtful to Sheep in a terrible Manner, though not ſo fatal as the others.

It is a much larger Plant than either of thoſe, and eaſier ſeen, but it is as often overlook'd or diſregarded.

The Root is compos'd of a vaſt Number of Fibres, which run deep in the Ground.

The Leaves riſe in little Tufts from this, and they are ſmall, and beautifully divided into a Number of leſſer Parts. They are of a fleſhy Subſtance, and of a faint green; but very often they are brown, and ſometimes reddiſh.

The Stalks are weak, and do not ſtand well upright: they are ſix or eight Inches long, and of a reddiſh Colour. They have many Leaves on them, in all Reſpects reſembling thoſe which grow from the Root; and at their Tops ſtand the Flowers.

Theſe are gaping, and of a full red; and they ſtand in reddiſh and ſtreaked Huſks.

All our wet Meadows abound with this Plant. Its juicy Subſtance and Taſte allure the Sheep to eat of it; in thoſe Places eſpecially where there is but little Graſs, which is too common a Caſe where this Plant is abundant; and it throws them into many Diſorders.

There is no Herb that has ſo ſpeedy, evident, and certain an Effect in fouling the Blood. The moſt healthy and clean Flock, will, in a Fortnight, grow ſcabby and ſcurfy upon the Skin; their Wool will be looſe, and they will be overrun with Vermin.

We have, in a preceding Part of this Work, delivered the Method of curing this Diſorder; and the Farmer muſt be careful to obſerve the Direction of removing the Sheep under Cure to a dry upland Paſture. Thoſe are Places where the Plant cannot grow; and there is no Security but that of the Creature's not feeding upon it, while under Cure.

CHAP. XII.

Of Spurge-Laurel.

THIS is a ſhrubby Plant of a very pleaſing Aſpect, and worthy to be introduced as an Ornament into Gardens; but it is one that the Farmer ſhould extirpate carefully from his Fields when he happens to have it. The ſingular Appearance renders it eaſily known, and it is only found on hilly Grounds.

The Root is compoſed of ſeveral long and tough Fibres.

The Stem is as thick as a Man's Thumb; and it is covered with a brown Bark.

Toward the Bottom it is naked; but there are numerous Leaves about the upper Part. The whole Shrub is three or four Foot high; and the Leaves grow principally at the extream Ends of the Branches.

They are long, broad, and of a firm Subſtance: their Colour is a deep green; and they in ſome Meaſure reſemble the Leaves of the common Laurel.

The Flowers grow in Cluſters below the Leaves, and they are ſmall and green.

After them come Berries, which when ripe are black: they are of a longiſh Shape, and have a ſingle large Kernel.

It is frequent on waſte Ground in hilly Places in many Parts of ENGLAND, and flowers very early in Spring.

Cattle are tempted by the Freſhneſs of the Leaves to taſte them; and they are ſo ſharp that they inflame their Mouths. Some will eat them in ſmall Quantities, and the Effect is terrible; they bring on the moſt violent Purgings with bloody Stools; and often theſe Complaints reſiſt the Power of all Remedies, and terminate in the Creature's Death.

I had in the Year 1740 an Inſtance of this in three Cows, which had been ſeen eating the Tops of this Shrub in APRIL. They all fell into theſe Purgings, and though every Method was uſed that could be thought of, all three died.

We have elſewhere in its Place informed the Huſbandman in what Manner he is to undertake the Cure of theſe Diſorders; but it is much better to prevent them by rooting out ſuch hurtful Plants, as are their worſt Cauſe.

The END.

This Day is publiſhed,

In FOUR VOLUMES, (Price bound 12s)

The WORKS of the moſt Reverend Dr. EDWARD SYNGE, late Lord Archbiſhop of *Tuam* in *Ireland*. Conſiſting of great Variety of TRACTS, wrote on the moſt *uſeful*, *intereſting*, and *important Points* and *Doctrines* of the CHRISTIAN RELIGION. The Subjects whereof may be ſeen at large in the following CONTENTS of each Volume, *viz.*

The Firſt Volume of Dr. SYNGE's WORKS, contains the following religious Tracts.

I. A Help to the Devout Performance of private Prayer. Price 1d, or 6s. a Hundred.
II. Plain Inſtructions for the Young and Ignorant, comprized in a ſhort and eaſy Expoſition of the Church Catechiſm. Price 3d, or 20s a Hundred.
III. Some ſhort and plain Directions for ſpending one Day well; by which, if every Day carefully obſerved, a Man may be much enabled, through God's Grace, to ſpend his whole Life well. Price 1d, or 6s a Hundred.
IV. An Anſwer to all the Excuſes and Pretences which Men ordinarily make for their not coming to the Holy Communion. To which is added, A brief Account of the End and Deſign of the Holy Communion, the Obligation to receive it, the Way to prepare for it, and the Behaviour of ourſelves both at and after it. Price 3d, or 20s a Hundred.
V. The Way to eternal Salvation plainly pointed out. Price 2d, or 12s a Hundred.
VI. A Perſuaſive to the Study of the Holy Scriptures, in a Letter to a ſober Gentleman of the Church of Rome. Price 4d, or 1l 5s a Hundred.
VII. Some Rules for the Conduct of Human Life. Price 3d, or 20s a Hundred.
VIII. An Eſſay on fooliſh Queſtions. Another on contending for the Faith, being the Subſtance of two Viſitation Sermons. Price 6d.
IX. Eternal Salvation the only End and Deſign of Religion. Price 3d.
X. The Divine Authority of Church Government and Epiſcopacy, ſtated and aſſerted upon Principles common to all Chriſtians. Price 4d.
XI. A Sermon before the Houſe of Commons at Dublin, October 23d, 1711. Price 4d.

Volume the Second of Dr. SYNGE's WORKS, contains the following Devotional Pieces.

I. A Gentleman's Religion in three Parts: The firſt contains the Principles of Natural Religion; the ſecond and third the Doctrines of Chriſtianity, both as to Faith and Practice. With an Appendix, wherein is proved, that nothing contrary to our Reaſon can poſſibly be the Object of our Belief; but that it is no juſt Exception againſt ſome of the Doctrines of Chriſtianity, that they are above our Reaſon. Price 2s.
II. An Eſſay towards making the Knowledge of Religion eaſy to the meaneſt Capacity: being a ſhort and plain Account of the Doctrines and Rules of Chriſtianity. Price 2d, or 12s a Hundred.
III. A plain and eaſy Method, whereby a Man of moderate Capacity may arrive at full Satisfaction in all Things that concern his everlaſting Salvation. To which is added, a Paraphraſe on St. Athanaſius's Creed. Price 6d, or 5s a Dozen.
IV. The Rule of Self Examination; or, The only Way of baniſhing Doubts and Scruples, and directing the Conſcience in the ſatisfactory Practice of all Chriſtian Duties. Price 4d.
V. The true Nature of an Oath; a Letter to a ſober Quaker, concerning his ſolemn Affirmation. Price 1d.

Volume the Third of Dr. SYNGE's WORKS, contains the following Religious Tracts.

I. Free Thinking in Matters of Religion ſtated and recommended. Price 4d.
II. Catholic Chriſtianity, or an Eſſay towards leſſening the Number of Controverſies among Chriſtians. Price 4d.
III. A Brief Diſcourſe of the Fundamentals of Chriſtianity, and the Uſe that is to be made of them. With an Appendix, in which, from the Principles laid down or ſuggeſted in the Diſcourſe, an Anſwer is given to three important Queſtions, the Determination whereof would much conduce to the reſtoring Communion between different Churches. Price 4d.
IV. The Authority of the Church in Matters of Religion. Price 4d.
V. The Wiſdom of being Religious. Price 3d.
VI. A Charitable Addreſs to all who are of the Communion of the Church of Rome. Price 6d, or 2l 2s a Hundred.
VII. An Anſwer to two Objections made againſt the Charitable Addreſs, to all who are of the Communion of the Church of Rome. Price 6d.
VIII. Honeſty the beſt Policy: An Eſſay concerning the true Way of rendring a Nation happy, and its Government firm and laſting. Price 2d, or 12s a Hundred.

Volume the Fourth of Dr. SYNGE's WORKS, concludes with the following Books of Piety and Devotion.

I. Religion tried by the Teſt of ſober and impartial Reaſon. Price 1s.
II. St. Paul's Deſcription of his own Religion opened and explained. Price 4d.
III. The true Churchman ſet in a juſt and clear Light; or an Eſſay towards the right Character of a faithful Son of the eſtabliſhed Church. Price 4d
IV. An Abſtract of the Ch. Catechiſm, briefly containing the Subſtance of all that is neceſſary to Salvation. Price 2d, or 12s a hundred.
V. Advice to a young Divine concerning Preaching. Price 1d.
VI. A ſincere Chriſtian and Convert from the Church of Rome, exemplified in the Life of Daniel Herley, a poor Iriſh Peaſant. Price 3d, or 20s a Hundred.
VII. Sober Thoughts for the Cure of Melancholy, eſpecially that which is religious. Price 2d, or, 12s a Hundred.
VIII. A Diſcourſe of Confirmation; in a Dialogue between the Miniſter of a Pariſh and a young Servant Maid named Sarah. Containing proper Inſtructions for ſuch as are to be confirmed. Humbly offered to the Conſideration of all Parents, and others who have the Care of educating Youth. Price 2d, or 12s a Hundred.
IX. Two Tracts; the one, Directions to a ſober Chriſtian for the acceptable Offering up the Lord's Prayer to God in his private Devotions; the other, Sober Thoughts on the Doctrine of Predeſtination. Price 1d. or 6s a Hundred.
X. The Root and Spring of true Virtue and Piety; a Sermon preached at Tuam, much enlarged. Price 4d.

N. B. Many of theſe Religious Tracts are diſperſed by the Society for promoting Chriſtian Knowledge.

The Books contained in the above mentioned four Volumes *are all ſold ſeparate*, with good Allowance to ſuch well diſpoſed Perſons as buy Numbers of each of them, to give away.

All Printed for, and Sold by THOMAS TRYE, Bookſeller, near *Grays-Inn-Gate, Holborn, LONDON.*
